9.8 The experience of the analyst performing GC/MS analyses is invaluable to the success of the methods. Each day that analysis is performed, the calibration verification standard should be evaluated to determine if the chromatographic system is operating properly. Questions that should be asked are: Do the peaks look normal? Is the response obtained comparable to the response from previous calibrations? Careful examination of the standard chromatogram can indicate whether the column is still performing acceptably, the injector is leaking, the injector septum needs replacing, etc. When any changes are made to the system (e.g., the column is changed, a septum is changed), see the guidance in Method 8000 regarding whether recalibration of the system must take place.

9.9 It is recommended that the laboratory adopt additional quality assurance practices for use with this method. The specific practices that are most productive depend upon the needs of the laboratory and the nature of the samples. Whenever possible, the laboratory should analyze standard reference materials and participate in relevant performance evaluation studies.

10.0 CALIBRATION AND STANDARDIZATION

See Sec 11.3 for information on calibration and standardization.

11.0 PROCEDURE

11.1 Sample preparation

11.1.1 Samples are normally prepared by one of the following methods prior to GC/MS analysis.

<u>Matrix</u>	<u>Methods</u>
Air (particulates and sorbent resin)	3542
Water (including TCLP leachates)	3510, 3520, 3535
Soil/sediment	3540, 3541, 3545, 3546, 3550, 3560, 3561
Waste	3540, 3541, 3545, 3546, 3550, 3560, 3561, 3580

11.1.2 In very limited applications, direct injection of the sample into the GC/MS system with a 10- μ L syringe may be appropriate. The quantitation limit is very high (approximately 10,000 μ g/L). Therefore, it is only appropriate where concentrations in excess of 10,000 μ g/L are expected.

11.2 Extract cleanup -- Cleanup procedures may not be necessary for a relatively clean sample matrix, but most extracts from environmental and waste samples will require additional preparation before analysis. The specific cleanup procedure used will depend on the nature of the sample to be analyzed and the data quality objectives for the measurements. General guidance for sample extract cleanup is provided in this section and in Method 3600.

Extracts may be cleaned up by any of the following methods prior to GC/MS analysis.

<u>Analytes of Interest</u>	<u>Methods</u>
Aniline and aniline derivatives	3620
Phenols	3630, 3640, 8041 ^a
Phthalate esters	3610, 3620, 3640
Nitrosamines	3610, 3620, 3640
Organochlorine pesticides	3610, 3620, 3630, 3640, 3660
PCBs	3620, 3630, 3660, 3665
Nitroaromatics and cyclic ketones	3620, 3640
Polynuclear aromatic hydrocarbons	3611, 3630, 3640
Haloethers	3620, 3640
Chlorinated hydrocarbons	3620, 3640
Organophosphorus pesticides	3620
Petroleum waste	3611, 3650
All base, neutral, and acid priority pollutants	3640

^a Method 8041 includes a derivatization technique and a GC/ECD analysis, if interferences are encountered on GC/FID.

11.3 Initial calibration

Establish the GC/MS operating conditions, using the following recommendations as guidance.

Mass range:	35-500 amu
Scan time:	# 1 sec/scan
Initial temperature:	40 EC, hold for 4 min
Temperature program:	40-320 EC at 10 EC/min
Final temperature:	320 EC, hold until 2 min after benzo[g,h,i]perylene elutes
Injector temperature:	250-300 EC
Transfer line temperature:	250-300 EC
Source temperature:	According to manufacturer's specifications
Injector:	Grob-type, splitless
Injection volume:	1-2 µL
Carrier gas:	Hydrogen at 50 cm/sec or helium at 30 cm/sec
Ion trap only:	Set axial modulation, manifold temperature, and emission current to manufacturer's recommendations

Split injection is allowed if the sensitivity of the mass spectrometer is sufficient.

11.3.1 The GC/MS system must be hardware-tuned such that injecting 50 ng or less of DFTPP meets the manufacturer's specified acceptance criteria or as listed in Table 3. The tuning criteria as outlined in Table 3 were developed using quadrupole mass spectrometer instrumentation and it is recognized that other tuning criteria may be more effective depending on the type of instrumentation, e.g., Time-of-Flight, Ion Trap, etc. In

these cases it would be appropriate to follow the manufacturer's tuning instructions or some other consistent tuning criteria. However, no matter which tuning criteria is selected, the system calibration must not begin until the tuning acceptance criteria are met with the sample analyses performed under the same conditions as the calibration standards.

11.3.1.1 In the absence of specific recommendations on how to acquire the mass spectrum of DFTPP from the instrument manufacturer, the following approach should be used: Three scans (the peak apex scan and the scans immediately preceding and following the apex) are acquired and averaged. Background subtraction is required, and must be accomplished using a single scan acquired within 20 scans of the elution of DFTPP. The background subtraction should be designed only to eliminate column bleed or instrument background ions. Do not subtract part of the DFTPP peak or any other discrete peak that does not coelute with DFTPP.

11.3.1.2 Use the DFTPP mass intensity criteria in the manufacturer's instructions as primary tuning acceptance criteria or those in Table 3 as default tuning acceptance criteria if the primary tuning criteria are not available. Alternatively, other documented tuning criteria may be used (e.g. CLP, or Method 625), provided that method performance is not adversely affected. The analyst is always free to choose criteria that are tighter than those included in this method or to use other documented criteria provided they are used consistently throughout the initial calibration, calibration verification, and sample analyses.

NOTE: All subsequent standards, samples, MS/MSDs, and blanks associated with a DFTPP analysis must use the identical mass spectrometer instrument conditions.

11.3.1.3 The GC/MS tuning standard solution should also be used to assess GC column performance and injection port inertness. Degradation of DDT to DDE and DDD should not exceed 20%. (See Method 8081 for the percent breakdown calculation.) Benzidine and pentachlorophenol should be present at their normal responses, and should not exceed a tailing factor of 2 given by the following equation:

$$\text{TailingFactor} = \frac{BC}{AB}$$

Where the peak is defined as follows: AC is the width at 10% height; DE is the height of peak and B is the height at 10% of DE. This equation compares the width of the back half of the peak to the width of the front half of the peak at 10% of the height. (See Figure 1 for an example tailing factor calculation.)

11.3.1.4 If degradation is excessive and/or poor chromatography is noted, the injection port may require cleaning. It may also be necessary to break off the first 6 to 12 in. of the capillary column. The use of a guard column (Sec. 6.1.6) between the injection port and the analytical column may help prolong analytical column performance life.

11.3.2 The internal standards selected in Sec. 7.5 should permit most of the components of interest in a chromatogram to have retention times of 0.80-1.20 relative to one of the internal standards. Use the base peak ion from the specific internal standard as the primary ion for quantitation (see Table 1). If interferences are noted, use the next most intense ion as the quantitation ion (e.g., for 1,4-dichlorobenzene- d_4 , use m/z 150 for quantitation).

11.3.3 Analyze 1-2 μL of each calibration standard (containing the compounds for quantitation and the appropriate surrogates and internal standards) and tabulate the area of the primary ion against concentration for each target analyte (as indicated in Table 1). A set of at least five calibration standards is necessary (see Sec. 7.7 and Method 8000). Alternate injection volumes may be used if the applicable quality control requirements for using this method are met. The injection volume must be the same for all standards and sample extracts. Figure 2 shows a chromatogram of a calibration standard containing base/neutral and acid analytes.

11.3.4 Initial calibration calculations

Calculate response factors (RFs) for each target analyte relative to one of the internal standards (see Table 5) as follows:

$$\text{RF} = \frac{A_s \times C_{is}}{A_{is} \times C_s}$$

where:

A_s = Peak area (or height) of the analyte or surrogate.

A_{is} = Peak area (or height) of the internal standard.

C_s = Concentration of the analyte or surrogate, in $\mu\text{g/L}$.

C_{is} = Concentration of the internal standard, in $\mu\text{g/L}$.

11.3.4.1 Calculate the mean response factor and the relative standard deviation (RSD) of the response factors for each target analyte using the following equations. The RSD should be less than or equal to 20% for each target analyte. It is also recommended that a minimum response factor for the most common target analytes, as noted in Table 4, be demonstrated for each individual calibration level as a means to ensure that these compounds are behaving as expected. In addition, meeting the minimum response factor criteria for the lowest calibration standard is critical in establishing and demonstrating the desired sensitivity. Due to the large number of compounds that may be analyzed by this method, some compounds will fail to meet this criteria. For these occasions, it is acknowledged that the failing compounds may not be critical to the specific project and therefore they may be used as qualified data or estimated values for screening purposes. The analyst should also strive to place more emphasis on meeting the calibration criteria for those compounds that are critical project compounds, rather than meeting the criteria for those less important compounds.

$$\text{mean RF} = \overline{RF} = \frac{\sum_{i=1}^n RF_i}{n}$$

$$SD = \sqrt{\frac{\sum_{i=1}^n (RF_i - \overline{RF})^2}{n-1}}$$

$$RSD = \frac{SD}{\overline{RF}} \times 100$$

where:

RF_i = RF for each of the calibration standards

\overline{RF} = mean RF for each compound from the initial calibration

n = Number of calibration standards, e.g., 5

11.3.4.2 If more than 10% of the compounds included with the initial calibration exceed the 20% RSD limit and do not meet the minimum correlation coefficient (0.99) for alternate curve fits, then the chromatographic system is considered too reactive for analysis to begin. Clean or replace the injector liner and/or capillary column, then repeat the calibration procedure beginning with Sec. 11.3.

11.3.5 Evaluation of retention times -- The relative retention time (RRT) of each target analyte in each calibration standard should agree within 0.06 RRT units. Late-eluting target analytes usually have much better agreement.

$$RRT = \frac{\text{Retention time of the analyte}}{\text{Retention time of the internal standard}}$$

11.3.6 Linearity of target analytes -- If the RSD of any target analyte is 20% or less, then the relative response factor is assumed to be constant over the calibration range, and the average relative response factor may be used for quantitation (Sec. 11.7.2).

11.3.6.1 If the RSD of any target analyte is greater than 20%, refer to Method 8000 for additional calibration options. One of the options must be applied to GC/MS calibration in this situation, or a new initial calibration must be performed. The average RF should not be used for compounds that have an RSD greater than 20% unless the concentration is reported as estimated.

11.3.6.2 When the RSD exceeds 20%, the plotting and visual inspection of a calibration curve can be a useful diagnostic tool. The inspection may indicate analytical problems, including errors in standard preparation, the presence of active sites in the chromatographic system, analytes that exhibit poor chromatographic behavior, etc.

11.3.6.3 Due to the large number of compounds that may be analyzed by this method, some compounds may fail to meet either the 20% RSD, minimum correlation coefficient criteria (0.99), or the acceptance criteria for alternative calibration procedures in Method 8000. Any calibration method described in Method 8000 may be used, but it should be used consistently. It is considered inappropriate once the calibration analyses are completed to select an alternative calibration procedure in order to pass the recommended criteria on a case-by-case basis. If compounds fail to meet these criteria, the associated concentrations may still be determined but they must be reported as estimated. In order to report non-detects, it must be demonstrated that there is adequate sensitivity to detect the failed compounds at the applicable lower quantitation limit.

11.4 GC/MS calibration verification -- Calibration verification consists of three steps that are performed at the beginning of each 12-hr analytical shift.

11.4.1 Prior to the analysis of samples or calibration standards, inject 50 ng or less of the DFTPP standard into the GC/MS system. The resultant mass spectrum for DFTPP must meet the criteria as outlined in Sec. 11.3.1 before sample analysis begins. These criteria must be demonstrated each 12-hr shift during which samples are analyzed.

11.4.2 The initial calibration function for each target analyte should be checked immediately after the first occurrence in the region of the middle of the calibration range with a standard from a source different from that used for the initial calibration. The value determined from the second source check should be within 30% of the expected concentration. An alternative recovery limit may be appropriate based on the desired project-specific data quality objectives. Quantitative sample analyses should not proceed for those analytes that fail the second source standard initial calibration verification. However, analyses may continue for those analytes that fail the criteria with an understanding these results could be used for screening purposes and would be considered estimated values.

11.4.3 The initial calibration (Sec. 11.3) for each compound of interest should be verified once every 12 hrs prior to sample analysis, using the introduction technique and conditions used for samples. This is accomplished by analyzing a calibration standard (containing all the compounds for quantitation) at a concentration either near the midpoint concentration for the calibrating range of the GC/MS or near the action level for the project. The results must be compared against the most recent initial calibration curve and should meet the verification acceptance criteria provided in Secs. 11.4.5 through 11.4.7.

NOTE: The DFTPP and calibration verification standard may be combined into a single standard as long as both tuning and calibration verification acceptance criteria for the project can be met without interferences.

11.4.4 A method blank should be analyzed prior to sample analyses in order to ensure that the total system (introduction device, transfer lines and GC/MS system) is free of contaminants. If the method blank indicates contamination, then it may be appropriate to analyze a solvent blank to demonstrate that the contamination is not a result of carryover from standards or samples. See Method 8000 for information regarding method blank performance criteria.

11.4.5 Calibration verification standard criteria

11.4.5.1 Each of the most common target analytes in the calibration verification standard should meet the minimum response factors as noted in Table 4. This criteria is particularly important when the common target analytes are also critical project-required compounds. This is the same check that is applied during the initial calibration.

11.4.5.2 If the minimum response factors are not met, the system should be evaluated, and corrective action should be taken before sample analysis begins. Possible problems include standard mixture degradation, injection port inlet contamination, contamination at the front end of the analytical column, and active sites in the column or chromatographic system.

11.4.5.3 All target compounds of interest must be evaluated using a 20% criterion. Use percent difference when performing the average response factor model calibration. Use percent drift when calibrating using a regression fit model. Refer to Method 8000 for guidance on calculating percent difference and drift.

11.4.5.4 If the percent difference or percent drift for a compound is less than or equal to 20%, then the initial calibration for that compound is assumed to be valid. Due to the large numbers of compounds that may be analyzed by this method, it is expected that some compounds will fail to meet the criterion. If the criterion is not met (i.e., greater than 20% difference or drift) for more than 20% of the compounds included in the initial calibration, then corrective action must be taken prior to the analysis of samples. In cases where compounds fail, they may still be reported as non-detects if it can be demonstrated that there was adequate sensitivity to detect the compound at the applicable quantitation limit. For situations when the failed compound is present, the concentrations must be reported as estimated values.

11.4.5.5 Problems similar to those listed under initial calibration could affect the ability to pass the calibration verification standard analysis. If the problem cannot be corrected by other measures, a new initial calibration must be generated. The calibration verification criteria must be met before sample analysis begins.

11.4.5.6 The method of linear regression analysis has the potential for a significant bias to the lower portion of a calibration curve, while the relative percent difference and quadratic methods of calibration do not have this potential bias. When calculating the calibration curves using the linear regression model, a minimum quantitation check on the viability of the lowest calibration point should be performed by re-fitting the response from the low concentration calibration standard back into the curve (see Method 8000 for additional details). It is not necessary to re-analyze a low concentration standard, rather the data system can recalculate the concentrations as if it were an unknown sample. The recalculated concentration of the low calibration point should be within $\pm 30\%$ of the standard's true concentration. Other recovery criteria may be applicable depending on the project's data quality objectives and for those situations the minimum quantitation check criteria should be outlined in a laboratory standard operating procedure, or a project-specific Quality Assurance Project Plan. Analytes which do not meet the minimum quantitation calibration re-fitting criteria should be considered "out of control" and corrective action such as redefining the lower limit of quantitation

and/or reporting those "out of control" target analytes as estimated when the concentration is at or near the lowest calibration point may be appropriate.

11.4.6 Internal standard retention time -- The retention times of the internal standards in the calibration verification standard must be evaluated immediately after or during data acquisition. If the retention time for any internal standard changes by more than 30 sec from that in the mid-point standard level of the most recent initial calibration sequence, then the chromatographic system must be inspected for malfunctions and corrections must be made, as required. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

11.4.7 Internal standard response -- If the EICP area for any of the internal standards in the calibration verification standard changes by a factor of two (-50% to +100%) from that in the mid-point standard level of the most recent initial calibration sequence, the mass spectrometer must be inspected for malfunctions and corrections must be made, as appropriate. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

11.5 GC/MS analysis of samples

11.5.1 It is highly recommended that sample extracts be screened on a GC/FID or GC/PID using the same type of capillary column used in the GC/MS system. This will minimize contamination of the GC/MS system from unexpectedly high concentrations of organic compounds.

11.5.2 Allow the sample extract to warm to room temperature. Just prior to analysis, add 10 μL of the internal standard solution to the 1 mL of concentrated sample extract obtained from sample preparation.

11.5.3 Inject an aliquot of the sample extract into the GC/MS system, using the same operating conditions that were used for the calibration (Sec. 11.3). The volume to be injected should include an appropriate concentration that is within the calibration range of base/neutral and acid surrogates using the surrogate solution as noted in Sec. 7.8. The injection volume must be the same volume that was used for the calibration standards.

11.5.4 If the response for any quantitation ion exceeds the initial calibration range of the GC/MS system, the sample extract must be diluted and reanalyzed. Additional internal standard solution must be added to the diluted extract to maintain the same concentration as in the calibration standards (usually 40 $\text{ng}/\mu\text{L}$, or other concentrations as appropriate, if a more sensitive GC/MS system is being used). Secondary ion quantitation should be used only when there are sample interferences with the primary ion.

NOTE: It may be a useful diagnostic tool to monitor internal standard retention times in all samples, spikes, blanks, and standards to effectively check drifting, method performance, poor injection execution, and anticipate the need for system inspection and/or maintenance. Internal standard responses (area counts) must be monitored in all samples, spikes, blanks for similar reasons. If the EICP area for any of the internal standards in samples, spikes and blanks changes by a factor of two (-50% to +100%) from the areas determined in the continuing calibration analyzed that day, corrective action must be taken. The samples, spikes or blanks should be reanalyzed or the data should be qualified.

11.5.4.1 When ions from a compound in the sample saturate the detector, this analysis should be followed by the analysis of an instrument blank consisting of clean solvent. If the blank analysis is not free of interferences, then the system must be decontaminated. Sample analysis may not resume until the blank analysis is demonstrated to be free of interferences. Contamination from one sample to the next on the instrument usually takes place in the syringe. If adequate syringe washes are employed, then carryover from high concentration samples can usually be avoided.

11.5.4.2 All dilutions should keep the response of the major constituents (previously saturated peaks) in the upper half of the linear range of the curve.

11.5.5 The use of selected ion monitoring (SIM) is acceptable for applications requiring quantitation limits below the normal range of electron impact mass spectrometry. However, SIM may provide a lesser degree of confidence in the compound identification, since less mass spectral information is available. Using the primary ion for quantitation and the secondary ions for confirmation set up the collection groups based on their retention times. The selected ions are nominal ions and most compounds have small mass defect, usually less than 0.2 amu, in their spectra. These mass defects should be used in the acquisition table. The dwell time may be automatically calculated by the laboratory's GC/MS software or manually calculated using the following formula. The total scan time should be less than 1,000 msec and produce at least 5 to 10 scans per chromatographic peak. The start and stop times for the SIM groups are determined from the full scan analysis using the formula below:

$$\text{Dwell Time for the Group} = \frac{\text{Scan Time (msec)}}{\text{Total Ions in the Group}}$$

Additional guidance for performing SIM analyses, in particular for PAHs and phenol target analyte compounds, can be found in the most recent CLP semivolatile organic methods statement of work (SOW). See the SIM sections from the following CLP SOW for further details: [EPA CLP Organics SOW](#). (Reference 14)

11.6 Analyte identification

11.6.1 The qualitative identification of compounds determined by this method is based on retention time and on comparison of the sample mass spectrum, after background correction, with characteristic ions in a reference mass spectrum. The reference mass spectrum must be generated by the laboratory using the conditions of this method. The characteristic ions from the reference mass spectrum are defined as the three ions of greatest relative intensity, or any ions over 30% relative intensity, if less than three such ions occur in the reference spectrum. Compounds are identified when the following criteria are met.

11.6.1.1 The intensities of the characteristic ions of a compound must maximize in the same scan or within one scan of each other. Selection of a peak by a data system target compound search routine where the search is based on the presence of a target chromatographic peak containing ions specific for the

target compound at a compound-specific retention time will be accepted as meeting this criterion.

11.6.1.2 The RRT of the sample component is within ± 0.06 RRT units of the RRT of the standard component.

11.6.1.3 The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum. (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%.) Use professional judgement in interpretation where interferences are observed.

11.6.1.4 Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 50% of the average of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. The resolution should be verified on the mid-point concentration of the initial calibration as well as the laboratory designated continuing calibration verification level if closely eluting isomers are to be reported (e.g., benzo(b)fluoranthene and benzo(k)fluoranthene).

11.6.1.5 Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e., a broadened peak with shoulder(s) or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important.

11.6.1.6 Examination of extracted ion current profiles of appropriate ions can aid in the selection of spectra and in qualitative identification of compounds. When analytes coelute (i.e., only one chromatographic peak is apparent), the identification criteria may be met, but each analyte spectrum will contain extraneous ions contributed by the coeluting compound.

11.6.2 For samples containing components not associated with the calibration standards, a library search may be made for the purpose of tentative identification. The necessity to perform this type of identification will be determined by the purpose of the analyses being conducted. Data system library search routines should not use normalization routines that would misrepresent the library or unknown spectra when compared to each other.

For example, the RCRA permit or waste delisting requirements may require the reporting of non-target analytes. Only after visual comparison of sample spectra with the nearest library searches may the analyst assign a tentative identification. Guidelines for tentative identification are:

- (1) Relative intensities of major ions in the reference spectrum (ions > 10% of the most abundant ion) should be present in the sample spectrum.
- (2) The relative intensities of the major ions should agree within $\pm 30\%$. (Example: For an ion with an abundance of 50% in the standard spectrum, the corresponding sample ion abundance must be between 20 and 80%.)

- (3) Molecular ions present in the reference spectrum should be present in the sample spectrum.
- (4) Ions present in the sample spectrum but not in the reference spectrum should be reviewed for possible background contamination or presence of coeluting compounds.
- (5) Ions present in the reference spectrum but not in the sample spectrum should be reviewed for possible subtraction from the sample spectrum because of background contamination or coeluting peaks. Data system library reduction programs can sometimes create these discrepancies.

11.7 Quantitation

11.7.1 Once a target compound has been identified, the quantitation of that compound will be based on the integrated abundance of the primary characteristic ion from the EICP.

11.7.1.1 It is highly recommended to use the integration produced by the software if the integration is correct because the software should produce more consistent integrations. However, manual integrations may be necessary when the software does not produce proper integrations because baseline selection is improper; the correct peak is missed; a coelution is integrated; the peak is partially integrated; etc. The analyst is responsible for ensuring that the integration is correct whether performed by the software or done manually.

11.7.1.2 Manual integrations should not be substituted for proper maintenance of the instrument or setup of the method (e.g. retention time updates, integration parameter files, etc). The analyst should seek to minimize manual integration by properly maintaining the instrument, updating retention times, and configuring peak integration parameters.

11.7.2 If the RSD of a compound's response factor is 20% or less, then the concentration in the extract may be determined using the average response factor (~~RF~~) from initial calibration data (Sec. 11.3.4). See Method 8000 for the equations describing internal standard calibration and either linear or non-linear calibrations.

11.7.3 Where applicable, the concentration of any non-target analytes identified in the sample (Sec. 11.6.2) should be estimated. The same formula as in Sec. 11.3.4 should be used with the following modifications: The areas A_x and A_{is} should be from the total ion chromatograms, and the RF for the compound should be assumed to be 1.

11.7.4 The resulting concentration should be reported indicating that the value is an estimate. Use the nearest internal standard free of interferences.

11.7.5 Quantitation of multicomponent compounds (e.g., Toxaphene, Aroclors, etc.) is beyond the scope of Method 8270. Normally, quantitation is performed using a GC/ECD, for example by using Methods 8081 or 8082. However, this method (8270) may be used to confirm the identification of these compounds, when the concentrations are at least 10 ng/ μ L in the concentrated sample extract.

11.7.6 Quantitation of multicomponent parameters such as diesel range organics (DROs) and total petroleum hydrocarbons (TPH) using the Method 8270 recommended internal standard quantitation technique is beyond the scope of this method. Typically,

analyses for these parameters are performed using GC/FID or GC with a MS detector capability that is available with Method 8015.

11.7.7 Structural isomers that produce very similar mass spectra should be quantitated as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 50% of the average of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. The resolution should be verified on the mid-point concentration of the initial calibration as well as the laboratory designated continuing calibration verification level if closely eluting isomers are to be reported (e.g., benzo(b)fluoranthene and benzo(k)fluoranthene).

12.0 DATA ANALYSIS AND CALCULATIONS

See Sec. 11.7 and Method 8000 for information on data analysis and calculations.

13.0 METHOD PERFORMANCE

13.1 Performance data and related information are provided in SW-846 methods only as examples and guidance. The data do not represent required performance criteria for users of the methods. Instead, performance criteria should be developed on a project-specific basis, and the laboratory should establish in-house QC performance criteria for the application of this method. These performance data are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

13.2 Single laboratory initial demonstration of capability data were generated from five replicate measurements using a modified continuous liquid-liquid extractor (Method 3520) with hydrophobic membrane. In this case only a single acid pH extraction was performed using the CLP calibration criteria and the applicable CLP target analytes. These data are presented in Table 6. Laboratories should generate their own acceptance criteria depending on the extraction and instrument conditions. (See Method 8000.)

13.3 Chromatograms from calibration standards analyzed with Day 0 and Day 7 samples were compared to detect possible deterioration of GC performance. These recoveries (using Method 3510 extraction) are presented in Table 7. These data are provided for guidance purposes only.

13.4 Method performance data using Method 3541 (automated Soxhlet extraction) are presented in Tables 8 and 9. Single laboratory accuracy and precision data were obtained for semivolatiles organics in a clay soil by spiking at a concentration of 6 mg/kg for each compound. The spiking solution was mixed into the soil during addition and then allowed to equilibrate for approximately 1 hour prior to extraction. The spiked samples were then extracted by Method 3541 (Automated Soxhlet). Three extractions were performed and each extract was analyzed by gas chromatography/mass spectrometry following Method 8270. The low recovery of the more volatile compounds is probably due to volatilization losses during equilibration. These data as listed were taken from Reference 7 and are provided for guidance purposes only.

13.5 Surrogate precision and accuracy data are presented in Table 10 from a field dynamic spiking study based on air sampling by Method 0010. The trapping media were prepared for analysis by Method 3542 and subsequently analyzed by this method (8270). These data are provided for guidance purposes only.

13.6 Single laboratory precision and bias data using Method 3545 (pressurized fluid extraction) for semivolatile organic compounds are presented in Table 11. The samples were conditioned spiked samples prepared and certified by a commercial supplier that contained 57 semivolatile organics at three concentrations (250, 2500, and 12,500 µg/kg) on three types of soil (clay, loam and sand). Spiked samples were extracted both by the Dionex Accelerated Solvent Extraction system and by the Perstorp Environmental Soxtec™ (automated Soxhlet). The data in Table 11 represent seven replicate extractions and analyses for each individual sample and were taken from Reference 9. The average recoveries from the three matrices for all analytes and all replicates relative to the automated Soxhlet data are as follows: clay 96.8%, loam 98.7% and sand 102.1%. The average recoveries from the three concentrations also relative to the automated Soxhlet data are as follows: low - 101.2%, mid - 97.2% and high - 99.2%. These data are provided for guidance purposes only.

13.7 Single laboratory precision and bias data using Method 3561 (SFE extraction of PAHs with a variable restrictor and solid trapping material) were obtained for the method analytes by the extraction of two certified reference materials (EC-1, a lake sediment from Environment Canada and HS-3, a marine sediment from the National Science and Engineering Research Council of Canada, both naturally-contaminated with PAHs). The SFE instrument used for these extractions was a Hewlett-Packard Model 7680. Analysis was by GC/MS. Average recoveries from six replicate extractions range from 85 to 148% (overall average of 100%) based on the certified value (or a Soxhlet value if a certified value was unavailable for a specific analyte) for the lake sediment. Average recoveries from three replicate extractions range from 73 to 133% (overall average of 92%) based on the certified value for the marine sediment. The data are found in Tables 12 and 13 and were taken from Reference 10. These data are provided for guidance purposes only.

13.8 Single laboratory precision and accuracy data using Method 3561 (SFE extraction of PAHs with a fixed restrictor and liquid trapping) were obtained for twelve of the method analytes by the extraction of a certified reference material (a soil naturally contaminated with PAHs). The SFE instrument used for these extractions was a Dionex Model 703-M. Analysis was by GC/MS. Average recoveries from four replicate extractions range from 60 to 122% (overall average of 89%) based on the certified value. The instrument conditions that were utilized to extract a 3.4 g sample were as follows: Pressure -- 300 atm; time -- 60 min.; extraction fluid -- CO₂; modifier -- 10% 1:1 (v/v) methanol/methylene chloride; Oven temperature -- 80 °C; Restrictor temperature -- 120 °C; and, trapping fluid -- chloroform (methylene chloride has also been used). The data are found in Table 14 and were taken from Reference 11. These data are provided for guidance purposes only.

13.9 Tables 15 and 16 contain single-laboratory precision and accuracy data for solid-phase extraction of TCLP buffer solutions spiked at two levels and extracted using Method 3535. These data are provided for guidance purposes only.

13.10 Table 17 contains multiple-laboratory data for solid-phase extraction of spiked TCLP soil leachates extracted using Method 3535. These data are provided for guidance purposes only.

13.11 Tables 18 through 22 contain single-laboratory PAH recovery data for microwave extraction of contaminated soils and standard reference materials using Method 3546. These data are provided for guidance purposes only.

14.0 POLLUTION PREVENTION

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity and/or toxicity of waste at the point of generation. Numerous opportunities for pollution prevention exist in laboratory operations. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.

14.2 For information about pollution prevention that may be applicable to laboratories and research institutions consult *Less is Better: Laboratory Chemical Management for Waste Reduction* available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th St., N.W. Washington, D.C. 20036, <http://www.acs.org>.

15.0 WASTE MANAGEMENT

The Environmental Protection Agency requires that laboratory waste management practices be conducted consistent with all applicable rules and regulations. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods and bench operations, complying with the letter and spirit of any sewer discharge permits and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management, consult *The Waste Management Manual for Laboratory Personnel* available from the American Chemical Society at the address listed in Sec. 14.2.

^a The data presented are representative of DB-5 type analytical columns

^b Compounds cannot be separated for quantitation

^c Substitute for the non-specific mixture, tricresyl phosphate

TABLE 2

EXAMPLE LOWER LIMITS OF QUANTITATION FOR SEMIVOLATILE ORGANICS

Compound	Lower Limits of Quantitation ^a	
	Ground water (µg/L)	Low Soil/Sediment ^b (µg/kg)
Acenaphthene	10	660
Acenaphthylene	10	660
Acetophenone	10	ND
2-Acetylaminofluorene	20	ND
1-Acetyl-2-thiourea	1000	ND
2-Aminoanthraquinone	20	ND
Aminoazobenzene	10	ND
4-Aminobiphenyl	20	ND
Anilazine	100	ND
o-Anisidine	10	ND
Anthracene	10	660
Aramite	20	ND
Azinphos-methyl	100	ND
Barban	200	ND
Benz(a)anthracene	10	660
Benzo(b)fluoranthene	10	660
Benzo(k)fluoranthene	10	660
Benzoic acid	50	3300
Benzo(g,h,i)perylene	10	660
Benzo(a)pyrene	10	660
p-Benzoquinone	10	ND
Benzyl alcohol	20	1300
Bis(2-chloroethoxy)methane	10	660
Bis(2-chloroethyl) ether	10	660
Bis(2-chloroisopropyl) ether	10	660
4-Bromophenyl phenyl ether	10	660
Bromoxynil	10	ND
Butyl benzyl phthalate	10	660
Captafol	20	ND
Captan	50	ND
Carbaryl	10	ND
Carbofuran	10	ND
Carbophenothion	10	ND
Chlorfenvinphos	20	ND
4-Chloroaniline	20	1300
Chlorobenzilate	10	ND
5-Chloro-2-methylaniline	10	ND
4-Chloro-3-methylphenol	20	1300

TABLE 2
(continued)

Compound	Lower Limits of Quantitation ^a	
	Ground water (µg/L)	Low Soil/Sediment ^b (µg/kg)
3-(Chloromethyl)pyridine hydrochloride	100	ND
2-Chloronaphthalene	10	660
2-Chlorophenol	10	660
4-Chlorophenyl phenyl ether	10	660
Chrysene	10	660
Coumaphos	40	ND
p-Cresidine	10	ND
Crotoxyphos	20	ND
2-Cyclohexyl-4,6-dinitrophenol	100	ND
Demeton-O	10	ND
Demeton-S	10	ND
Diallate (cis or trans)	10	ND
Diallate (trans or cis)	10	ND
2,4-Diaminotoluene	20	ND
Dibenz(a,j)acridine	10	ND
Dibenz(a,h)anthracene	10	660
Dibenzofuran	10	660
Dibenzo(a,e)pyrene	10	ND
Di-n-butyl phthalate	10	ND
Dichlone	NA	ND
1,2-Dichlorobenzene	10	660
1,3-Dichlorobenzene	10	660
1,4-Dichlorobenzene	10	660
3,3'-Dichlorobenzidine	20	1300
2,4-Dichlorophenol	10	660
2,6-Dichlorophenol	10	ND
Dichlorovos	10	ND
Dicrotophos	10	ND
Diethyl phthalate	10	660
Diethylstilbestrol	20	ND
Diethyl sulfite	100	ND
Dimethoate	20	ND
3,3'-Dimethoxybenzidine	100	ND
Dimethylaminoazobenzene	10	ND
7,12-Dimethylbenz(a)anthracene	10	ND
3,3'-Dimethylbenzidine	10	ND
2,4-Dimethylphenol	10	660
Dimethyl phthalate	10	660
1,2-Dinitrobenzene	40	ND

Trifluralin	10	ND
2,4,5-Trimethylaniline	10	ND
Trimethyl phosphate	10	ND
1,3,5-Trinitrobenzene	10	ND
Tris(2,3-dibromopropyl) phosphate	200	ND
Tri-p-tolyl phosphate(h)	10	ND

TABLE 2
(continued)

- ^a Sample lower limits of quantitation are highly matrix-dependent and those listed here are provided for guidance and may not always be achievable.
- ^b Lower limits of quantitation listed for soil/sediment are based on wet weight. When data are reported on a dry weight basis, the lower limits will be higher based on the % dry weight of each sample. These lower limits are based on a 30-g sample and gel permeation chromatography cleanup.

ND = Not Determined

NA = Not Applicable

Other Matrices

Factor^c

High-concentration soil and sludges by ultrasonic extractor
Non-water miscible waste

7.5
75

^cLower limit of quantitation = (Lower limit of quantitation for low soil/sediment given above in Table 2) x (Factor)

TABLE 3

DFTPP KEY IONS AND ION ABUNDANCE CRITERIA^{a,b}

Mass	Ion Abundance Criteria
51	10-80% of Base Peak
68	< 2% of mass 69
70	< 2% of mass 69
127	10-80% of Base Peak
197	< 2% of mass 198
198	Base peak, or > 50% of Mass 442
199	5-9% of mass 198
275	10-60% of Base Peak
365	> 1% of mass 198
441	present but < 24% of mass 442
442	Base Peak, or > 50% of mass 198
443	15-24% of mass 442

^a The majority of the data are taken from Reference 13 (Method 525.2).

^b The criteria in this table are intended to be used as default criteria for quadrupole instrumentation if optimized manufacturer's operating conditions are not available. Alternate tuning criteria may be employed (e.g., CLP or Method 625), provided that method performance is not adversely affected. See Sec. 11.3.1

TABLE 4

RECOMMENDED MINIMUM RESPONSE FACTOR CRITERIA FOR INITIAL AND
CONTINUING CALIBRATION VERIFICATION USING THE SUGGESTED IONS
FROM TABLE 1

Semivolatile Compounds	Minimum Response Factor (RF)
Benzaldehyde	0.010
Phenol	0.800
Bis(2-chloroethyl)ether	0.700
2-Chlorophenol	0.800

2,4,5-Trichlorophenol	50	47.7	95.4
2,4,6-Trichlorophenol	50	49.2	98.4

\bar{x} = Average recovery for five initial demonstration of capability measurements, in µg/L

^a Extraction using acidic pH only with a modified continuous liquid-liquid extractor with hydrophobic membrane according to Method 3520. These values are for guidance only. Appropriate derivation of acceptance criteria for similar extraction conditions may result in much different recovery ranges. See Method 8000 for information on developing and updating acceptance criteria for method performance.

TABLE 7
EXTRACTION EFFICIENCY AND AQUEOUS STABILITY RESULTS

Compound	Percent Recovery, Day 0		Percent Recovery, Day 7	
	Mean	RSD	Mean	RSD
3-Amino-9-ethylcarbazole	80	8	73	3
4-Chloro-1,2-phenylenediamine	91	1	108	4

GAS CHROMATOGRAM OF BASE/NEUTRAL AND ACID CALIBRATION STANDARD

No. L-10

Aroclor PCBs

SW-846 Method 8082

METHOD 8082

POLYCHLORINATED BIPHENYLS (PCBs)
BY GAS CHROMATOGRAPHY

1.0 SCOPE AND APPLICATION

1.1 Method 8082 is used to determine the concentrations of polychlorinated biphenyls (PCBs) as Aroclors or as individual PCB congeners in extracts from solid and aqueous matrices. Open-tubular, capillary columns are employed with electron capture detectors (ECD) or electrolytic conductivity detectors (ELCD). When compared to packed columns, these fused-silica, open-tubular columns offer improved resolution, better selectivity, increased sensitivity, and faster analysis. The target compounds listed below may be determined by either a single- or dual-column analysis system. The PCB congeners listed below have been tested by this method, and the method may be appropriate for additional congeners.

Compound	CAS Registry No.	IUPAC #
Aroclor 1016	12674-11-2	-
Aroclor 1221	11104-28-2	-
Aroclor 1232	11141-16-5	-
Aroclor 1242	53469-21-9	-
Aroclor 1248	12672-29-6	-
Aroclor 1254	11097-69-1	-
Aroclor 1260	11096-82-5	-
2-Chlorobiphenyl	2051-60-7	1
2,3-Dichlorobiphenyl	16605-91-7	5
2,2',5-Trichlorobiphenyl	37680-65-2	18
2,4',5-Trichlorobiphenyl	16606-02-3	31
2,2',3,5'-Tetrachlorobiphenyl	41464-39-5	44
2,2',5,5'-Tetrachlorobiphenyl	35693-99-3	52
2,3',4,4'-Tetrachlorobiphenyl	32598-10-0	66
2,2',3,4,5'-Pentachlorobiphenyl	38380-02-8	87
2,2',4,5,5'-Pentachlorobiphenyl	37680-73-2	101
2,3,3',4',6-Pentachlorobiphenyl	38380-03-9	110
2,2',3,4,4',5'-Hexachlorobiphenyl	35065-28-2	138
2,2',3,4,5,5'-Hexachlorobiphenyl	52712-04-6	141
2,2',3,5,5',6-Hexachlorobiphenyl	52663-63-5	151
2,2',4,4',5,5'-Hexachlorobiphenyl	35065-27-1	153
2,2',3,3',4,4',5-Heptachlorobiphenyl	35065-30-6	170
2,2',3,4,4',5,5'-Heptachlorobiphenyl	35065-29-3	180
2,2',3,4,4',5',6-Heptachlorobiphenyl	52663-69-1	183
2,2',3,4',5,5',6-Heptachlorobiphenyl	52663-68-0	187
2,2',3,3',4,4',5,5',6-Nonachlorobiphenyl	40186-72-9	206

1.2 Aroclors are multi-component mixtures. When samples contain more than one Aroclor, a higher level of analyst expertise is required to attain acceptable levels of qualitative and quantitative analysis. The same is true of Aroclors that have been subjected to environmental degradation ("weathering") or degradation by treatment technologies. Such weathered multi-component mixtures may have significant differences in peak patterns than those of Aroclor standards.

1.3 Quantitation of PCBs as Aroclors is appropriate for many regulatory compliance determinations, but is particularly difficult when the Aroclors have been weathered by long exposure in the environment. Therefore, this method provides procedures for the determination of selected individual PCB congeners. The 19 PCB congeners listed above have been tested by this method.

1.4 The PCB congener approach potentially affords greater quantitative accuracy when PCBs are known to be present. As a result, this method may be used to determine Aroclors, some PCB congeners, or "total PCBs," depending on regulatory requirements and project needs. The congener method is of particular value in determining weathered Aroclors. However, analysts should use caution when using the congener method when regulatory requirements are based on Aroclor concentrations.

1.5 Compound identification based on single-column analysis should be confirmed on a second column, or should be supported by at least one other qualitative technique. This method describes analytical conditions for a second gas chromatographic column that can be used to confirm the measurements made with the primary column. GC/MS Method 8270 is also recommended as a confirmation technique when sensitivity permits (Sec. 8.0).

1.6 This method also describes a dual-column option. The option allows a hardware configuration of two analytical columns joined to a single injection port. The option allows one injection to be used for dual-column analysis. Analysts are cautioned that the dual-column option may not be appropriate when the instrument is subject to mechanical stress, many samples are to be run in a short period, or when highly contaminated samples are analyzed.

1.7 The analyst must select columns, detectors and calibration procedures most appropriate for the specific analytes of interest in a study. Matrix-specific performance data must be established and the stability of the analytical system and instrument calibration must be established for each analytical matrix (e.g., hexane solutions from sample extractions, diluted oil samples, etc.). Example chromatograms and GC conditions are provided as guidance.

1.8 The MDLs for Aroclors vary in the range of 0.054 to 0.90 µg/L in water and 57 to 70 µg/kg in soils. Estimated quantitation limits may be determined using the data in Table 1.

1.9 This method is restricted to use by, or under the supervision of, analysts experienced in the use of gas chromatographs (GC) and skilled in the interpretation of gas chromatograms. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 A measured volume or weight of sample (approximately 1 L for liquids, 2 g to 30 g for solids) is extracted using the appropriate matrix-specific sample extraction technique.

2.2 Aqueous samples are extracted at neutral pH with methylene chloride using Method 3510 (separatory funnel), Method 3520 (continuous liquid-liquid extractor), or other appropriate technique.

2.3 Solid samples are extracted with hexane-acetone (1:1) or methylene chloride-acetone (1:1) using Method 3540 (Soxhlet), Method 3541 (automated Soxhlet), or other appropriate technique.

2.4 Extracts for PCB analysis may be subjected to a sulfuric acid/potassium permanganate cleanup (Method 3665) designed specifically for these analytes. This cleanup technique will remove (destroy) many single component organochlorine or organophosphorus pesticides. Therefore, Method 8082 is not applicable to the analysis of those compounds. Instead, use Method 8081.

2.5 After cleanup, the extract is analyzed by injecting a 2- μ L aliquot into a gas chromatograph with a narrow- or wide-bore fused silica capillary column and electron capture detector (GC/ECD).

2.6 The chromatographic data may be used to determine the seven Aroclors in Sec. 1.1, individual PCB congeners, or total PCBs.

3.0 INTERFERENCES

3.1 Refer to Methods 3500 (Sec. 3.0, in particular), 3600, and 8000 for a discussion of interferences.

3.2 Interferences co-extracted from the samples will vary considerably from matrix to matrix. While general cleanup techniques are referenced or provided as part of this method, unique samples may require additional cleanup approaches to achieve desired degrees of discrimination and quantitation. Sources of interference in this method can be grouped into three broad categories.

3.2.1 Contaminated solvents, reagents, or sample processing hardware.

3.2.2 Contaminated GC carrier gas, parts, column surfaces, or detector surfaces.

3.2.3 Compounds extracted from the sample matrix to which the detector will respond.

3.3 Interferences by phthalate esters introduced during sample preparation can pose a major problem in PCB determinations.

3.3.1 Common flexible plastics contain varying amounts of phthalate esters which are easily extracted or leached from such materials during laboratory operations. Interferences from phthalate esters can best be minimized by avoiding contact with any plastic materials and checking all solvents and reagents for phthalate contamination.

3.3.2 Exhaustive cleanup of solvents, reagents and glassware may be required to eliminate background phthalate ester contamination.

3.3.3 These materials can be removed through the use of Method 3665 (sulfuric acid/permanganate cleanup).

3.4 Cross-contamination of clean glassware routinely occurs when plastics are handled during extraction steps, especially when solvent-wetted surfaces are handled. Glassware must be scrupulously cleaned.

Clean all glassware as soon as possible after use by rinsing with the last solvent used. This should be followed by detergent washing with hot water, and rinses with tap water and organic-free

reagent water. Drain the glassware, and dry it in an oven at 130°C for several hours, or rinse with methanol and drain. Store dry glassware in a clean environment.

NOTE: Oven-drying of glassware used for PCB analysis can increase contamination because PCBs are readily volatilized in the oven and spread to other glassware. Therefore, exercise caution, and do not dry glassware from samples containing high concentrations of PCBs with glassware that may be used for trace analyses.

3.5 Elemental sulfur (S_8) is readily extracted from soil samples and may cause chromatographic interferences in the determination of PCBs. Sulfur can be removed through the use of Method 3660.

4.0 APPARATUS AND MATERIALS

4.1 Gas chromatograph - An analytical system complete with gas chromatograph suitable for on-column and split-splitless injection and all required accessories including syringes, analytical columns, gases, electron capture detectors (ECD), and recorder/integrator or data system.

4.2 GC columns

This method describes procedures for both single-column and dual-column analyses. The single-column approach involves one analysis to determine that a compound is present, followed by a second analysis to confirm the identity of the compound (Sec. 8.4 describes how GC/MS confirmation techniques may be employed). The single-column approach may employ either narrow-bore (≤ 0.32 mm ID) columns or wide-bore (0.53 mm ID) columns. The dual-column approach involves a single injection that is split between two columns that are mounted in a single gas chromatograph. The dual-column approach employs only wide-bore (0.53 mm ID) columns. A third alternative is to employ dual columns mounted in a single GC, but with each column connected to a separate injector and a separate detector.

The columns listed in this section were the columns used to develop the method performance data. Listing these columns in this method is not intended to exclude the use of other columns that may be developed. Laboratories may use other capillary columns provided that they document method performance (e.g., chromatographic resolution, analyte breakdown, and MDLs) that equals or exceeds the performance specified in this method.

4.2.1 Narrow-bore columns for single-column analysis (use both columns to confirm compound identifications unless another confirmation technique such as GC/MS is employed). Narrow bore columns should be installed in split/splitless (Grob-type) injectors.

4.2.1.1 30 m x 0.25 or 0.32 mm ID fused silica capillary column chemically bonded with SE-54 (DB-5 or equivalent), 1 μ m film thickness.

4.2.1.2 30 m x 0.25 mm ID fused silica capillary column chemically bonded with 35 percent phenyl methylpolysiloxane (DB-608, SPB-608, or equivalent), 2.5 μ m coating thickness, 1 μ m film thickness.

4.2.2 Wide-bore columns for single-column analysis (use two of the three columns listed to confirm compound identifications unless another confirmation technique such as GC/MS is employed). Wide-bore columns should be installed in 1/4 inch injectors, with deactivated liners designed specifically for use with these columns.

4.2.2.1 30 m x 0.53 mm ID fused silica capillary column chemically bonded with 35 percent phenyl methylpolysiloxane (DB-608, SPB-608, RTx-35, or equivalent), 0.5 µm or 0.83 µm film thickness.

4.2.2.2 30 m x 0.53 mm ID fused silica capillary column chemically bonded with 14% cyanopropylmethylpolysiloxane (DB-1701, or equivalent), 1.0 µm film thickness.

4.2.2.3 30 m x 0.53 mm ID fused silica capillary column chemically bonded with SE-54 (DB-5, SPB-5, RTx-5, or equivalent), 1.5 µm film thickness.

4.2.3 Wide-bore columns for dual-column analysis (choose one of the two pairs of columns listed below).

4.2.3.1 Column pair 1

30 m x 0.53 mm ID fused silica capillary column chemically bonded with SE-54 (DB-5, SPB-5, RTx-5, or equivalent), 1.5 µm film thickness.

30 m x 0.53 mm ID fused silica capillary column chemically bonded with 14% cyanopropylmethylpolysiloxane (DB-1701, or equivalent), 1.0 µm film thickness.

Column pair 1 is mounted in a press-fit Y-shaped glass 3-way union splitter (J&W Scientific, Catalog No. 705-0733) or a Y-shaped fused-silica connector (Restek, Catalog No. 20405), or equivalent.

4.2.3.2 Column pair 2

30 m x 0.53 mm ID fused silica capillary column chemically bonded with SE-54 (DB-5, SPB-5, RTx-5, or equivalent), 0.83 µm film thickness.

30 m x 0.53 mm ID fused silica capillary column chemically bonded with 14% cyanopropylmethylpolysiloxane (DB-1701, or equivalent), 1.0 µm film thickness.

Column pair 2 is mounted in an 8 in. deactivated glass injection tee (Supelco, Catalog No. 2-3665M), or equivalent.

4.3 Column rinsing kit - Bonded-phase column rinse kit (J&W Scientific, Catalog No. 430-3000), or equivalent.

4.4 Volumetric flasks - 10-mL and 25-mL, for preparation of standards.

5.0 REAGENTS

5.1 Reagent grade or pesticide grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

NOTE: Store the standard solutions (stock, composite, calibration, internal, and surrogate standards) at 4°C in polytetrafluoroethylene (PTFE)-sealed containers

in the dark. When a lot of standards is prepared, it is recommended that aliquots of that lot be stored in individual small vials. All stock standard solutions must be replaced after one year or sooner if routine QC (Sec. 8.0) indicates a problem. All other standard solutions must be replaced after six months or sooner if routine QC (Sec. 8.0) indicates a problem.

5.2 Sample extracts prepared by Methods 3510, 3520, 3540, 3541, 3545, or 3550 need to undergo a solvent exchange step prior to analysis. The following solvents are necessary for dilution of sample extracts. All solvent lots should be pesticide quality or equivalent and should be determined to be phthalate-free.

5.2.1 n-Hexane, C_6H_{14}

5.2.2 Isooctane, $(CH_3)_3CCH_2CH(CH_3)_2$

5.3 The following solvents may be necessary for the preparation of standards. All solvent lots must be pesticide quality or equivalent and should be determined to be phthalate-free.

5.3.1 Acetone, $(CH_3)_2CO$

5.3.2 Toluene, $C_6H_5CH_3$

5.4 Organic-free reagent water - All references to water in this method refer to organic-free reagent water as defined in Chapter One.

5.5 Stock standard solutions (1000 mg/L) - May be prepared from pure standard materials or can be purchased as certified solutions.

5.5.1 Prepare stock standard solutions by accurately weighing about 0.0100 g of pure compound. Dissolve the compound in isooctane or hexane and dilute to volume in a 10-mL volumetric flask. If compound purity is 96 percent or greater, the weight may be used without correction to calculate the concentration of the stock standard solution.

5.5.2 Commercially-prepared stock standard solutions may be used at any concentration if they are certified by the manufacturer or by an independent source.

5.6 Calibration standards for Aroclors

5.6.1 A standard containing a mixture of Aroclor 1016 and Aroclor 1260 will include many of the peaks represented in the other five Aroclor mixtures. As a result, a multi-point initial calibration employing a mixture of Aroclors 1016 and 1260 at five concentrations should be sufficient to demonstrate the linearity of the detector response without the necessity of performing initial calibrations for each of the seven Aroclors. In addition, such a mixture can be used as a standard to demonstrate that a sample does not contain peaks that represent any one of the Aroclors. This standard can also be used to determine the concentrations of either Aroclor 1016 or Aroclor 1260, should they be present in a sample. Prepare a minimum of five calibration standards containing equal concentrations of both Aroclor 1016 and Aroclor 1260 by dilution of the stock standard with isooctane or hexane. The concentrations should correspond to the expected range of concentrations found in real samples and should bracket the linear range of the detector.

5.6.2 Single standards of each of the other five Aroclors are required to aid the analyst in pattern recognition. Assuming that the Aroclor 1016/1260 standards described in Sec. 5.6.1 have been used to demonstrate the linearity of the detector, these single standards of the remaining five Aroclors are also used to determine the calibration factor for each Aroclor. Prepare a standard for each of the other Aroclors. The concentrations should correspond to the mid-point of the linear range of the detector.

5.7 Calibration standards for PCB congeners

5.7.1 If results are to be determined for individual PCB congeners, then standards for the pure congeners must be prepared. The table in Sec. 1.1 lists 19 PCB congeners that have been tested by this method along with the IUPAC numbers designating these congeners. This procedure may be appropriate for other congeners as well.

5.7.2 Stock standards may be prepared in a fashion similar to that described for the Aroclor standards, or may be purchased as commercially-prepared solutions. Stock standards should be used to prepare a minimum of five concentrations by dilution of the stock standard with isooctane or hexane. The concentrations should correspond to the expected range of concentrations found in real samples and should bracket the linear range of the detector.

5.8 Internal standard

5.8.1 When PCB congeners are to be determined, the use of an internal standard is highly recommended. Decachlorobiphenyl may be used as an internal standard, added to each sample extract prior to analysis, and included in each of the initial calibration standards.

5.8.2 When PCBs are to be determined as Aroclors, an internal standard is not used, and decachlorobiphenyl is employed as a surrogate (see Sec. 5.8).

5.9 Surrogate standards

5.9.1 When PCBs are to be determined as Aroclors, decachlorobiphenyl is used as a surrogate, and is added to each sample prior to extraction. Prepare a solution of decachlorobiphenyl at a concentration of 5 mg/L in acetone.

5.9.2 When PCB congeners are to be determined, decachlorobiphenyl is recommended for use as an internal standard, and therefore, cannot also be used as a surrogate. Therefore, tetrachloro-meta-xylene may be used as a surrogate for PCB congener analysis. Prepare a solution of tetrachloro-meta-xylene at a concentration of 5 mg/L in acetone.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 See Chapter Four, Organic Analytes for sample collection and preservation instructions.

6.2 Extracts must be stored under refrigeration in the dark and analyzed within 40 days of extraction.

7.0 PROCEDURE

7.1 Sample extraction

7.1.1 Refer to Chapter Two and Method 3500 for guidance in choosing the appropriate extraction procedure. In general, water samples are extracted at a neutral pH with methylene chloride using a separatory funnel (Method 3510) or a continuous liquid-liquid extractor (Method 3520) or other appropriate procedure. Solid samples are extracted with hexane-acetone (1:1) or methylene chloride-acetone (1:1) using one of the Soxhlet extraction (Method 3540 or 3541) procedures, ultrasonic extraction (Method 3550), or other appropriate procedure.

NOTE: Use of hexane-acetone generally reduces the amount of interferences that are extracted and improves signal-to-noise.

7.1.2 Reference materials, field-contaminated samples, or spiked samples should be used to verify the applicability of the selected extraction technique to each new sample type. Such samples should contain or be spiked with the compounds of interest in order to determine the percent recovery and the limit of detection for that sample type (see Chapter One). When other materials are not available and spiked samples are used, they should be spiked with the analytes of interest, either specific Aroclors or PCB congeners. When the presence of specific Aroclors is not anticipated, the Aroclor 1016/1260 mixture may be an appropriate choice for spiking. See Methods 3500 and 8000 for guidance on demonstration of initial method proficiency as well as guidance on matrix spikes for routine sample analysis.

7.2 Extract cleanup

Refer to Methods 3660 and 3665 for information on extract cleanup.

7.3 GC conditions

This method allows the analyst to choose between a single-column or a dual-column configuration in the injector port. Either wide- or narrow-bore columns may be used. See Sec. 7.7 for information on techniques for making positive identifications of multi-component analytes.

7.3.1 Single-column analysis

This capillary GC/ECD method allows the analyst the option of using 0.25-0.32 mm ID capillary columns (narrow-bore) or 0.53 mm ID capillary columns (wide-bore). The use of narrow-bore (0.25-0.32 mm ID) columns is recommended when the analyst requires greater chromatographic resolution. Use of narrow-bore columns is suitable for relatively clean samples or for extracts that have been prepared with one or more of the clean-up options referenced in the method. Wide-bore columns (0.53 mm ID) are suitable for more complex environmental and waste matrices.

7.3.2 Dual-column analysis

The dual-column/dual-detector approach involves the use of two 30 m x 0.53 mm ID fused-silica open-tubular columns of different polarities, thus different selectivities towards the target compounds. The columns are connected to an injection tee and ECD detectors.

7.3.3 GC temperature programs and flow rates

7.3.3.1 Table 2 lists GC operating conditions for the analysis of PCBs as Aroclors for single-column analysis, using either narrow-bore or wide-bore capillary columns. Table 3 lists GC operating conditions for the dual-column analysis. Use the conditions in these tables as guidance and establish the GC temperature program and flow rate necessary to separate the analytes of interest.

7.3.3.2 When determining PCBs as congeners, difficulties may be encountered with coelution of congener 153 and other sample components. When determining PCBs as Aroclors, chromatographic conditions should be adjusted to give adequate separation of the characteristic peaks in each Aroclor (see Sec. 7.4.6).

7.3.3.3 Tables 4 and 5 summarize the retention times of up to 73 Aroclor peaks determined during dual-column analysis using the operating conditions listed in Table 2. These retention times are provided as guidance as to what may be achieved using the GC columns, temperature programs, and flow rates described in this method. Note that the peak numbers used in these tables are *not* the IUPAC congener numbers, but represent the elution order of the peaks on these GC columns.

7.3.3.4 Once established, the same operating conditions must be used for the analysis of samples and standards.

7.4 Calibration

7.4.1 Prepare calibration standards as described in Sec. 5.0. Refer to Method 8000 (Sec. 7.0) for proper calibration techniques for both initial calibration and calibration verification. When PCBs are to be determined as congeners, the use of internal standard calibration is highly recommended. Therefore, the calibration standards must contain the internal standard (see Sec. 5.7) at the same concentration as the sample extracts. When PCBs are to be determined as Aroclors, external standard calibration should be used.

NOTE: Because of the sensitivity of the electron capture detector, the injection port and column should always be cleaned prior to performing the initial calibration.

7.4.2 When PCBs are to be quantitatively determined as congeners, an initial five-point calibration must be performed that includes standards for all the target analytes (congeners).

7.4.3 When PCBs are to be quantitatively determined as Aroclors, the initial calibration consists of two parts, described below.

7.4.3.1 As noted in Sec. 5.6.1, a standard containing a mixture of Aroclor 1016 and Aroclor 1260 will include many of the peaks represented in the other five Aroclor mixtures. Thus, such a standard may be used to demonstrate the linearity of the detector and that a sample does not contain peaks that represent any one of the Aroclors. This standard can also be used to determine the concentrations of either Aroclor 1016 or Aroclor 1260, should they be present in a sample. Therefore, an initial five-point calibration is performed using the mixture of Aroclors 1016 and 1260 described in Sec. 5.6.1.

7.4.3.2 Standards of the other five Aroclors are necessary for pattern recognition. These standards are also used to determine a single-point calibration factor for each Aroclor, assuming that the Aroclor 1016/1260 mixture in Sec. 7.3.4.1 has been used to describe the detector response. The standards for these five Aroclors should be analyzed before the analysis of any samples, and may be analyzed before or after the analysis of the five 1016/1260 standards in Sec. 7.3.4.1.

7.4.3.3 In situations where only a few Aroclors are of interest for a specific project, the analyst may employ a five-point initial calibration of each of the Aroclors of interest (e.g., five standards of Aroclor 1232 if this Aroclor is of concern) and not use the 1016/1260 mixture described in Sec. 7.4.3.1 or the pattern recognition standards described in 7.4.3.2.

7.4.4 Establish the GC operating conditions appropriate for the configuration (single-column or dual column, Sec. 7.3). Optimize the instrumental conditions for resolution of the target compounds and sensitivity. A final temperature of 240-270°C may be required to elute decachlorobiphenyl. Use of injector pressure programming will improve the chromatography of late eluting peaks.

NOTE: Once established, the same operating conditions must be used for both calibrations and sample analyses.

7.4.5 A 2-μL injection of each calibration standard is recommended. Other injection volumes may be employed, provided that the analyst can demonstrate adequate sensitivity for the compounds of interest.

7.4.6 Record the peak area (or height) for each congener or each characteristic Aroclor peak to be used for quantitation.

7.4.6.1 A minimum of 3 peaks must be chosen for each Aroclor, and preferably 5 peaks. The peaks must be characteristic of the Aroclor in question. Choose peaks in the Aroclor standards that are at least 25% of the height of the largest Aroclor peak. For each Aroclor, the set of 3 to 5 peaks should include at least one peak that is unique to that Aroclor. Use at least five peaks for the Aroclor 1016/1260 mixture, none of which should be found in both of these Aroclors.

7.4.6.2 Late-eluting Aroclor peaks are generally the most stable in the environment. Table 6 lists diagnostic peaks in each Aroclor, along with their retention times on two GC columns suitable for single-column analysis. Table 7 lists 13 specific PCB congeners found in Aroclor mixtures. Table 8 lists PCB congeners with corresponding retention times on a DB-5 wide-bore GC column. Use these tables as guidance in choosing the appropriate peaks.

7.4.7 When determining PCB congeners by the internal standard procedure, calculate the response factor (RF) for each congener in the calibration standards relative to the internal standard, decachlorobiphenyl, using the equation that follows.

$$RF = \frac{A_s \times C_{is}}{A_{is} \times C_s}$$

where:

- A_s = Peak area (or height) of the analyte or surrogate.
 A_{is} = Peak area (or height) of the internal standard.
 C_s = Concentration of the analyte or surrogate, in $\mu\text{g/L}$.
 C_{is} = Concentration of the internal standard, in $\mu\text{g/L}$.

7.4.8 When determining PCBs as Aroclors by the external standard technique, calculate the calibration factor (CF) for each characteristic Aroclor peak in each of the initial calibration standards (from either Sec. 7.4.3.1 or 7.4.3.2) using the equation below.

$$CF = \frac{\text{Peak Area (or Height) in the Standard}}{\text{Total Mass of the Standard Injected (in nanograms)}}$$

Five sets of calibration factors will be generated for the Aroclor 1016/1260 mixture, each set consisting of the calibration factors for each of the five (or more) peaks chosen for this mixture. The single standard for each of the other Aroclors (see Sec. 7.4.3.1) will generate at least three calibration factors, one for each selected peak.

7.4.9 The response factors or calibration factors from the initial calibration are used to evaluate the linearity of the initial calibration. This involves the calculation of the mean response or calibration factor, the standard deviation, and the relative standard deviation (RSD) for each congener or Aroclor peak. See Method 8000 for the specifics of the evaluation of the linearity of the calibration and guidance on performing non-linear calibrations. When the Aroclor 1016/1260 mixture is used to demonstrate the detector response, the calibration model (see Method 8000) chosen for this mixture must be applied to the other five Aroclors for which only single standards are analyzed. If multi-point calibration is performed for individual Aroclors (see Sec. 7.4.3.3), use the calibration factors from those standards to evaluate linearity.

7.5 Retention time windows

Retention time windows are crucial to the identification of target compounds. Absolute retention times are used for the identification of PCBs as Aroclors. When PCBs are determined as congeners by an internal standard technique, absolute retention times may be used in conjunction with relative retention times (relative to the internal standard). Retention time windows are established to compensate for minor shifts in absolute retention times as a result of sample loadings and normal chromatographic variability. The width of the retention time window should be carefully established to minimize the occurrence of both false positive and false negative results. Tight retention time windows may result in false negatives and/or may cause unnecessary reanalysis of samples when surrogates or spiked compounds are erroneously not identified. Overly wide retention time windows may result in false positive results that cannot be confirmed upon further analysis. Analysts should consult Method 8000 for the details of establishing retention time windows.

7.6 Gas chromatographic analysis of sample extracts

7.6.1 The same GC operating conditions used for the initial calibration must be employed for samples analyses.

7.6.2 Verify calibration each 12-hour shift by injecting calibration verification standards prior to conducting any sample analyses. A calibration standard must also be injected at intervals of not less than once every twenty samples (after every 10 samples is recommended to minimize the number of samples requiring re-injection when QC limits are exceeded) and at the end of the analysis sequence. For Aroclor analyses, the calibration verification standard should be a mixture of Aroclor 1016 and Aroclor 1260. The calibration verification process

does not *require* analysis of the other Aroclor standards used for pattern recognition, but the analyst may wish to include a standard for one of these Aroclors after the 1016/1260 mixture used for calibration verification throughout the analytical sequence.

7.6.2.1 The calibration factor for each analyte calculated from the calibration verification standard (CF_v) must not exceed a difference of more than ± 15 percent when compared to the mean calibration factor from the initial calibration curve.

$$\% \text{ Difference} = \frac{\overline{CF} - CF_v}{\overline{CF}} \times 100$$

7.6.2.2 When internal standard calibration is used for PCB congeners, the response factor calculated from the calibration verification standard (RF_v) must not exceed a ± 15 percent difference when compared to the mean response factor from the initial calibration

$$\% \text{ Difference} = \frac{\overline{RF} - RF_v}{\overline{RF}} \times 100$$

7.6.2.3 If this criterion is exceeded for any calibration factor or response factor, inspect the gas chromatographic system to determine the cause and perform whatever maintenance is necessary before verifying calibration and proceeding with sample analysis.

7.6.2.4 If routine maintenance does not return the instrument performance to meet the QC requirements (Sec. 8.2) based on the last initial calibration, then a new initial calibration must be performed.

7.6.3 Inject a 2- μ L aliquot of the concentrated sample extract. Record the volume injected to the nearest 0.05 μ L and the resulting peak size in area (or peak height) units.

7.6.4 Qualitative identifications of target analytes are made by examination of the sample chromatograms, as described in Sec. 7.7.

7.6.5 Quantitative results are determined for each identified analyte (Aroclors or congeners), using the procedures described in Secs. 7.8 and 7.9 for either the internal or the external calibration procedure (Method 8000). If the responses in the sample chromatogram exceed the calibration range of the system, dilute the extract and reanalyze. Peak height measurements are recommended over peak area when overlapping peaks cause errors in area integration.

7.6.6 Each sample analysis must be bracketed with an acceptable initial calibration, calibration verification standard(s) (each 12-hour shift), or calibration standards interspersed within the samples. When a calibration verification standard fails to meet the QC criteria, all samples that were injected after the last standard that last met the QC criteria must be re-injected.

Multi-level standards (mixtures or multi-component analytes) are highly recommended to ensure that detector response remains stable for all analytes over the calibration range.

7.6.7 Sample injections may continue for as long as the calibration verification standards and standards interspersed with the samples meet instrument QC requirements. It is *recommended* that standards be analyzed after every 10 samples (*required* after every 20 samples and at the end of a set) to minimize the number of samples that must be re-injected when the standards fail the QC limits. The sequence ends when the set of samples has been injected or when qualitative or quantitative QC criteria are exceeded.

7.6.8 If the peak response is less than 2.5 times the baseline noise level, the validity of the quantitative result may be questionable. The analyst should consult with the source of the sample to determine whether further concentration of the sample is warranted.

7.6.9 Use the calibration standards analyzed during the sequence to evaluate retention time stability. If any of the standards fall outside their daily retention time windows, the system is out of control. Determine the cause of the problem and correct it.

7.6.10 If compound identification or quantitation is precluded due to interference (e.g., broad, rounded peaks or ill-defined baselines are present) cleanup of the extract or replacement of the capillary column or detector is warranted. Rerun the sample on another instrument to determine if the problem results from analytical hardware or the sample matrix. Refer to Method 3600 for the procedures to be followed in sample cleanup.

7.7 Qualitative identification

The identification of PCBs as either Aroclors or congeners using this method with an electron capture detector is based on agreement between the retention times of peaks in the sample chromatogram with the retention time windows established through the analysis of standards of the target analytes. See Method 8000 for information on the establishment of retention time windows.

Tentative identification of an analyte occurs when a peak from a sample extract falls within the established retention time window for a specific target analyte. Each tentative identification must be confirmed: using a second GC column of dissimilar stationary phase (as in the dual-column analysis), based on a clearly identifiable Aroclor pattern, or using another technique such as GC/MS (see Sec. 7.10).

7.7.1 When simultaneous analyses are performed from a single injection (the dual-column GC configuration described in Sec. 7.3), it is not practical to designate one column as the analytical (primary) column and the other as the confirmation column. Since the calibration standards are analyzed on both columns, the results for both columns must meet the calibration acceptance criteria. If the retention times of the peaks on both columns fall within the retention time windows on the respective columns, then the target analyte identification has been confirmed.

7.7.2 The results of a single column/single injection analysis may be confirmed on a second, dissimilar, GC column. In order to be used for confirmation, retention time windows must have been established for the second GC column. In addition, the analyst must demonstrate the sensitivity of the second column analysis. This demonstration must include the analysis of a standard of the target analyte at a concentration at least as low as the concentration estimated from the primary analysis. That standard may be either the individual congeners, individual Aroclor or the Aroclor 1016/1260 mixture.

7.7.3 When samples are analyzed from a source known to contain specific Aroclors, the results from a single-column analysis may be confirmed on the basis of a clearly recognizable Aroclor pattern. This approach should not be attempted for samples from unknown or unfamiliar sources or for samples that appear to contain mixtures of Aroclors. In order to employ this approach, the analyst must document:

- The peaks that were evaluated when comparing the sample chromatogram and the Aroclor standard.
- The absence of major peaks representing any other Aroclor.
- The source-specific information indicating that Aroclors are anticipated in the sample (e.g., historical data, generator knowledge, etc.).

This information should either be provided to the data user or maintained by the laboratory.

7.7.4 See Sec. 7.10 for information on GC/MS confirmation.

7.8 Quantitation of PCBs as congeners

7.8.1 The quantitation of PCB congeners is accomplished by the comparison of the sample chromatogram to those of the PCB congener standards, using the internal standard technique (see Method 8000). Calculate the concentration of each congener.

7.8.2 Depending on project requirements, the PCB congener results may be reported as congeners, or may be summed and reported as total PCBs. The analyst should use caution when using the congener method for quantitation when regulatory requirements are based on Aroclor concentrations. See Sec. 9.3.

7.9 Quantitation of PCBs as Aroclors

The quantitation of PCB residues as Aroclors is accomplished by comparison of the sample chromatogram to that of the most similar Aroclor standard. A choice must be made as to which Aroclor is most similar to that of the residue and whether that standard is truly representative of the PCBs in the sample.

7.9.1 Use the individual Aroclor standards (not the 1016/1260 mixtures) to determine the pattern of peaks on Aroclors 1221, 1232, 1242, 1248, and 1254. The patterns for Aroclors 1016 and 1260 will be evident in the mixed calibration standards.

7.9.2 Once the Aroclor pattern has been identified, compare the responses of 3 to 5 major peaks in the single-point calibration standard for that Aroclor with the peaks observed in the sample extract. The amount of Aroclor is calculated using the individual calibration factor for each of the 3 to 5 characteristic peaks chosen in Sec. 7.4.6.1. and the calibration model (linear or non-linear) established from the multi-point calibration of the 1016/1260 mixture. A concentration is determined using each of the characteristic peaks and then those 3 to 5 concentrations are averaged to determine the concentration of that Aroclor.

7.9.3 Weathering of PCBs in the environment and changes resulting from waste treatment processes may alter the PCBs to the point that the pattern of a specific Aroclor is no longer recognizable. Samples containing more than one Aroclor present similar problems. If the purpose of the analysis is not regulatory compliance monitoring on the basis of Aroclor

concentrations, then it may be more appropriate to perform the analyses using the PCB congener approach described in this method. If results in terms of Aroclors are required, then the quantitation as Aroclors may be performed by measuring the total area of the PCB pattern and quantitating on the basis of the Aroclor standard that is most similar to the sample. Any peaks that are not identifiable as PCBs on the basis of retention times should be subtracted from the total area. When quantitation is performed in this manner, the problems should be fully described for the data user and the specific procedures employed by the analyst should be thoroughly documented.

7.10 GC/MS confirmation may be used in conjunction with either single-or dual-column analysis if the concentration is sufficient for detection by GC/MS.

7.10.1 Full-scan quadrupole GC/MS will normally require a higher concentration of the analyte of interest than full-scan ion trap or selected ion monitoring techniques. The concentrations will be instrument-dependent, but values for full-scan quadrupole GC/MS may be as high as 10 ng/ μ L in the final extract, while ion trap or SIM may only require a concentration of 1 ng/ μ L.

7.10.2 The GC/MS must be calibrated for the specific target analytes. When using SIM techniques, the ions and retention times should be characteristic of the Aroclors to be confirmed.

7.10.3 GC/MS confirmation should be accomplished by analyzing the same extract used for GC/ECD analysis and the extract of the associated blank.

7.10.4 The base/neutral/acid extract and the associated blank may be used for GC/MS confirmation if the surrogates and internal standards do not interfere. However, if the compounds are *not* detected in the base/neutral/acid extract, then GC/MS analysis of the pesticide extract should be performed.

7.10.5 A QC reference sample containing the compound must also be analyzed by GC/MS. The concentration of the QC reference sample must demonstrate that those PCBs identified by GC/ECD can be confirmed by GC/MS.

7.11 Chromatographic System Maintenance as Corrective Action

When system performance does not meet the established QC requirements, corrective action is required, and may include one or more of the following.

7.11.1 Splitter connections

For dual columns which are connected using a press-fit Y-shaped glass splitter or a Y-shaped fused-silica connector, clean and deactivate the splitter port insert or replace with a cleaned and deactivated splitter. Break off the first few inches (up to one foot) of the injection port side of the column. Remove the columns and solvent backflush according to the manufacturer's instructions. If these procedures fail to eliminate the degradation problem, it may be necessary to deactivate the metal injector body and/or replace the columns.

7.11.2 Metal injector body

Turn off the oven and remove the analytical columns when the oven has cooled. Remove the glass injection port insert (instruments with on-column injection). Lower the

injection port temperature to room temperature. Inspect the injection port and remove any noticeable foreign material.

7.11.2.1 Place a beaker beneath the injector port inside the oven. Using a wash bottle, rinse the entire inside of the injector port with acetone and then rinse it with toluene, catching the rinsate in the beaker.

7.11.2.2 Consult the manufacturer's instructions regarding deactivating the injector port body. Glass injection port liners may require deactivation with a silanizing solution containing dimethyldichlorosilane.

7.11.3 Column rinsing

The column should be rinsed with several column volumes of an appropriate solvent. Both polar and nonpolar solvents are recommended. Depending on the nature of the sample residues expected, the first rinse might be water, followed by methanol and acetone. Methylene chloride is a good final rinse and in some cases may be the only solvent required. The column should then be filled with methylene chloride and allowed to stand flooded overnight to allow materials within the stationary phase to migrate into the solvent. The column is then flushed with fresh methylene chloride, drained, and dried at room temperature with a stream of ultrapure nitrogen.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One and Method 8000 for specific quality control (QC) procedures. Quality control procedures to ensure the proper operation of the various sample preparation techniques can be found in Method 3500. If an extract cleanup procedure was performed, refer to Method 3600 for the appropriate quality control procedures. Each laboratory should maintain a formal quality assurance program. The laboratory should also maintain records to document the quality of the data generated.

8.2 Quality control procedures necessary to evaluate the GC system operation are found in Method 8000, Sec. 7.0 and include evaluation of retention time windows, calibration verification and chromatographic analysis of samples.

8.3 Initial Demonstration of Proficiency - Each laboratory must demonstrate initial proficiency with each sample preparation and determinative method combination it utilizes, by generating data of acceptable accuracy and precision for target analytes in a clean matrix. The laboratory must also repeat the following operations whenever new staff are trained or significant changes in instrumentation are made. See Method 8000, Sec. 8.0 for information on how to accomplish this demonstration.

8.3.1 The QC Reference Sample concentrate (Method 3500) should contain PCBs as Aroclors at 10-50 mg/L for water samples, or PCBs as congeners at the same concentrations. A 1-mL volume of this concentrate spiked into 1 L of organic-free reagent water will result in a sample concentration of 10-50 µg/L. If Aroclors are not expected in samples from a particular source, then prepare the QC reference samples with a mixture of Aroclors 1016 and 1260. However, when specific Aroclors are known to be present or expected in samples, the specific Aroclors should be used for the QC reference sample.

8.3.1.1 The frequency of analysis of the QC reference sample analysis is equivalent to a minimum of 1 per 20 samples or 1 per batch if less than 20 samples.

8.3.1.2 If the recovery of any compound found in the QC reference sample is less than 80 percent or greater than 120 percent of the certified value, the laboratory performance is judged to be out of control, and the problem must be corrected. A new set of calibration standards should be prepared and analyzed.

8.3.2 Include a calibration standard after each group of 20 samples (it is *recommended* that a calibration standard be included after every 10 samples to minimize the number of repeat injections) in the analysis sequence as a calibration check. The response factors for the calibration should be within 15 percent of the initial calibration. When this continuing calibration is out of this acceptance window, the laboratory should stop analyses and take corrective action.

8.3.3 Whenever quantitation is accomplished using an internal standard, internal standards must be evaluated for acceptance. The measured area of the internal standard must be no more than 50 percent different from the average area calculated during calibration. When the internal standard peak area is outside the limit, all samples that fall outside the QC criteria must be reanalyzed.

8.4 Sample Quality Control for Preparation and Analysis - The laboratory must also have procedures for documenting the effect of the matrix on method performance (precision, accuracy, and detection limit). At a minimum, this includes the analysis of QC samples including a method blank, a matrix spike, a duplicate, and a laboratory control sample (LCS) in each analytical batch and the addition of surrogates to each field sample and QC sample.

8.4.1 Documenting the effect of the matrix should include the analysis of at least one matrix spike and one duplicate unspiked sample or one matrix spike/matrix spike duplicate pair. The decision on whether to prepare and analyze duplicate samples or a matrix spike/matrix spike duplicate must be based on a knowledge of the samples in the sample batch. If samples are not expected to contain target analytes, laboratories should use a matrix spike and matrix spike duplicate pair, spiked with the Aroclor 1016/1260 mixture. However, when specific Aroclors are known to be present or expected in samples, the specific Aroclors should be used for spiking. If samples are expected to contain target analytes, then laboratories may use one matrix spike and a duplicate analysis of an unspiked field sample.

8.4.2 A Laboratory Control Sample (LCS) should be included with each analytical batch. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS is spiked with the same analytes at the same concentrations as the matrix spike. When the results of the matrix spike analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix.

8.4.3 See Method 8000, Sec. 8.0 for the details on carrying out sample quality control procedures for preparation and analysis.

8.5 Surrogate recoveries - The laboratory must evaluate surrogate recovery data from individual samples versus the surrogate control limits developed by the laboratory. See Method 8000, Sec. 8.0 for information on evaluating surrogate data and developing and updating surrogate limits.

8.6 It is recommended that the laboratory adopt additional quality assurance practices for use with this method. The specific practices that are most productive depend upon the needs of the laboratory and the nature of the samples. Whenever possible, the laboratory should analyze standard reference materials and participate in relevant performance evaluation studies.

9.0 METHOD PERFORMANCE

9.1 The MDL is defined in Chapter One. The MDLs for Aroclors vary in the range of 0.054 to 0.90 µg/L in water and 57 to 70 µg/kg in soils, with the higher MDLs for the more heavily chlorinated Aroclors. Estimated quantitation limits may be determined using the data in Table 1.

9.2 Estimated quantitation limits for PCBs as congeners vary by congener, in the range of 5 - 25 ng/L in water and 160 - 800 ng/kg in soils, with the higher values for the more heavily chlorinated congeners.

9.3 The accuracy and precision obtainable with this method depend on the sample matrix, sample preparation technique, optional cleanup techniques, and calibration procedures used. Table 9 provides single laboratory recovery data for Aroclors spiked into clay and soil and extracted with automated Soxhlet. Table 10 provides multiple laboratory data on the precision and accuracy for Aroclors spiked into soil and extracted by automated Soxhlet.

9.4 During method performance studies, the concentrations determined as Aroclors were larger than those obtained using the congener method. In certain soils, interference prevented the measurement of congener 66. Recoveries of congeners from soils spiked with Aroclor 1254 and Aroclor 1260 were between 80% and 90%. Recoveries of congeners from environmental reference materials ranged from 51 - 66% of the certified Aroclor values.

TABLE 1

FACTORS FOR DETERMINATION OF ESTIMATED QUANTITATION LIMITS^a (EQLs)
FOR VARIOUS MATRICES

Matrix	Factor
Ground water	10
Low-concentration soil by sonication with GPC cleanup	670
High-concentration soil and sludges by sonication	10,000
Non-water miscible waste	100,000

^aEQL = [MDL for water (see Sec. 1.8)] times [Factor in this table]

For nonaqueous samples, the factor is on a wet-weight basis. Sample EQLs are highly matrix-dependent. EQLs determined using these factors are provided as guidance and may not always be achievable.

TABLE 2

GC OPERATING CONDITIONS FOR PCBs AS AROCLORS
SINGLE COLUMN ANALYSIS

Narrow-bore columns

Narrow-bore Column 1 - 30 m x 0.25 or 0.32 mm ID fused silica capillary column chemically bonded with SE-54 (DB-5 or equivalent), 1 μ m film thickness.

Carrier gas (He)	16 psi
Injector temperature	225°C
Detector temperature	300°C
Initial temperature	100°C, hold 2 minutes
Temperature program	100°C to 160°C at 15°C/min, followed by 160°C to 270°C at 5°C/min
Final temperature	270°C

Narrow-bore Column 2 - 30 m x 0.25 mm ID fused silica capillary column chemically bonded with 35 percent phenyl methylpolysiloxane (DB-608, SPB-608, or equivalent) 25 μ m coating thickness, 1 μ m film thickness

Carrier gas (N ₂)	20 psi
Injector temperature	225°C
Detector temperature	300°C
Initial temperature	160°C, hold 2 minutes
Temperature program	160°C to 290°C at 5°C/min
Final temperature	290°C, hold 1 min

Wide-bore columns

Wide-bore Column 1 - 30 m x 0.53 mm ID fused silica capillary column chemically bonded with 35 percent phenyl methylpolysiloxane (DB-608, SPB-608, RTx-35, or equivalent), 0.5 μ m or 0.83 μ m film thickness.

Wide-bore Column 2 - 30 m x 0.53 mm ID fused silica capillary column chemically bonded with 14% cyanopropylmethylpolysiloxane (DB-1701, or equivalent), 1.0 μ m film thickness.

Carrier gas (He)	5-7 mL/minute
Makeup gas (argon/methane [P-5 or P-10] or N ₂)	30 mL/min
Injector temperature	250°C
Detector temperature	290°C
Initial temperature	150°C, hold 0.5 minute
Temperature program	150°C to 270°C at 5°C/min
Final temperature	270°C, hold 10 min

(continued)

TABLE 2 (cont.)

GC OPERATING CONDITIONS FOR PCBs AS AROCLORS
SINGLE COLUMN ANALYSIS

Wide-bore Columns (continued)

Wide-bore Column 3 - 30 m x 0.53 mm ID fused silica capillary column chemically bonded with SE-54 (DB-5, SPB-5, RTx-5, or equivalent), 1.5 μ m film thickness.

Carrier gas (He)	6 mL/minute
Makeup gas (argon/methane [P-5 or P-10] or N ₂)	30 mL/min
Injector temperature	205°C
Detector temperature	290°C
Initial temperature	140°C, hold 2 min
Temperature program	140°C to 240°C at 10°C/min, hold 5 minutes at 240°C, 240°C to 265°C at 5°C/min
Final temperature	265°C, hold 18 min

TABLE 3

GC OPERATING CONDITIONS FOR PCBs AS AROCLORS
FOR THE DUAL COLUMN METHOD OF ANALYSIS
HIGH TEMPERATURE, THICK FILM

Column 1 - DB-1701 or equivalent, 30 m x 0.53 mm ID, 1.0 μm film thickness.

Column 2 - DB-5 or equivalent, 30 m x 0.53 mm ID, 1.5 μm film thickness.

Carrier gas (He) flow rate	6 mL/min
Makeup gas (N ₂) flow rate	20 mL/min
Temperature program	0.5 min hold 150°C to 190°C, at 12°C/min, 2 min hold 190°C to 275°C, at 4°C/min, 10 min hold
Injector temperature	250°C
Detector temperature	320°C
Injection volume	2 μL
Solvent	Hexane
Type of injector	Flash vaporization
Detector type	Dual ECD
Range	10
Attenuation	64 (DB-1701)/64 (DB-5)
Type of splitter	J&W Scientific press-fit Y-shaped inlet splitter

December 2007

Introduction

EPA Method 1699 determines organochlorine, organophosphorus, triazine, and pyrethroid pesticides in environmental samples by high resolution gas chromatography/high resolution mass spectrometry (HRGC/HRMS) using isotope dilution and internal standard quantitation techniques. This method has been developed for use with aqueous, solid, tissue and biosolids matrices.

Disclaimer

This method has been reviewed by the Engineering and Analytical Support Branch of the Engineering and Analysis Division (EAD) in OST. The method is available for general use, but has not been published in 40 CFR Part 136. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

Method 1699: Pesticides in Water, Soil, Sediment, Biosolids, and Tissue by HRGC/HRMS

1.0 Scope and Application

- 1.1 Method 1699 is for determination of selected organochlorine, organo-phosphorus, triazine, and pyrethroid pesticides in multi-media environmental samples by high resolution gas chromatography/high resolution mass spectrometry (HRGC/HRMS).
- 1.2 This Method was developed for use in EPA's Clean Water Act (CWA) programs; other applications are possible. It is based on existing EPA methods (Reference 1) and procedures developed at Axys Analytical Services (Reference 2).
- 1.3 The analytes that may be measured by this method and their corresponding Chemical Abstracts Service Registry Numbers (CASRNs) and ambient water quality criteria are listed in Table 1.
- 1.4 The detection limits and quantitation levels in this Method are usually dependent on the level of interferences rather than instrumental limitations. The method detection limits (MDLs; 40 CFR 136, appendix B) and minimum levels of quantitation (MLs; 68 FR 11790) in Table 1 are the levels at which pesticides can be determined in the absence of interferences.
- 1.5 This Method is restricted for use by analysts experienced in HRGC/HRMS or under the close supervision of such qualified persons. Each laboratory that uses this Method must demonstrate the ability to generate acceptable results using the procedure in Section 9.2.
- 1.6 This method is performance-based which means that you may modify the method to improve performance (e.g., to overcome interferences or improve the accuracy or precision of the results) provided that you meet all performance requirements in this method. These requirements for establishing equivalency of a modification are in Section 9.1.2. For Clean Water Act (CWA) uses, additional flexibility is described at 40 CFR 136.6. Modifications not in the scope of Part 136.6 or in Section 9 of this method may require prior review and approval.

2.0 Summary of Method

Flow charts that summarize procedures for sample preparation, extraction, and analysis are given in Figure 1 for aqueous and solid samples, Figure 2 for multi-phase samples, and Figure 3 for tissue samples.

2.1 Extraction (Section 12)

- 2.1.1 Aqueous samples (samples containing less than one percent solids) – Stable isotopically labeled analogs of the pesticides are spiked into a 1-L sample. The sample is extracted at neutral pH with methylene chloride using separatory funnel extraction (SFE) or continuous liquid/liquid extraction (CLLE).
- 2.1.2 Solid, semi-solid, and multi-phase samples (excluding municipal sludge and tissue) – The labeled compounds are spiked into a sample containing 10 g (dry weight) of solids. Samples containing multiple phases are pressure filtered and any aqueous liquid is discarded. Coarse solids are ground or homogenized. Any non-aqueous liquid from multi-phase samples is combined with the solids and extracted with methylene chloride, methylene chloride:hexane (1:1) or acetone:hexane (1:1) in a Soxhlet extractor or with toluene in a Soxhlet/Dean-Stark (SDS) extractor (Reference 3).
- 2.1.3 Municipal sludges are homogenized, spiked with labeled compounds, and Soxhlet extracted with dichloromethane.
- 2.1.4 Fish and other tissue – A 20-g aliquot of sample is homogenized, and a 10-g aliquot is spiked with the labeled compounds. The sample is mixed with anhydrous sodium sulfate, allowed to dry for 30 minutes minimum, and extracted for 18 - 24 hours using methylene chloride in a Soxhlet extractor. The extract is evaporated to dryness, and the lipid content is determined.

2.2 Concentration (Section 12)

- 2.2.1 Extracts are macro-concentrated using rotary evaporation, a heating mantle, or a Kuderna-Danish evaporator.
- 2.2.2 Extracts to be injected into the HRGC/HRMS are concentrated to a final volume of 20 μ L using nitrogen evaporation (blowdown).

2.3 Cleanup (Section 13)

- 2.3.1 Extracts of aqueous, solid or mixed phase samples are cleaned up using an aminopropyl SPE column followed by a microsilica column.
- 2.3.2 Extracts may be further cleaned up using gel permeation chromatography (GPC) or solid-phase cartridge techniques.

- 2.3.3** Extracts in which the organo-chlorine pesticides only are to be determined may be further cleaned up using silica gel, Florisil, or alumina chromatography.
- 2.4** Determination by GC/HRMS – Immediately prior to injection, a labeled injection internal standard is added to each extract and an aliquot of the extract is injected into the gas chromatograph (GC). The analytes are separated by the GC and detected by a high-resolution ($\geq 8,000$) mass spectrometer. Two exact m/z's for each pesticide are monitored throughout a pre-determined retention time window.
- 2.5** An individual pesticide is identified by comparing the GC retention time and ion-abundance ratio of two exact m/z's with the corresponding retention time of an authentic standard and the theoretical or acquired ion-abundance ratio of the two exact m/z's.
- 2.6** Quantitative analysis is performed in one of two ways using selected ion current profile (SICP) areas:
- 2.6.1** For pesticides for which a labeled analog is available, the GC/HRMS is multi-point calibrated and the concentration is determined using the isotope dilution technique.
- 2.6.2** Pesticides for which a labeled analog is not available are determined using the internal standard technique. The labeled compounds are used as internal standards, affording recovery correction for all pesticides.
- 2.7** The quality of the analysis is assured through reproducible calibration and testing of the extraction, cleanup, and GC/MS systems.

3.0 Definitions and units of measure

Definitions and units of measure are given in the glossary at the end of this Method.

4.0 Interferences

- 4.1** Solvents, reagents, glassware, and other sample processing hardware may yield artifacts, elevated baselines, and/or lock-mass suppression causing misinterpretation of chromatograms. Specific selection of reagents and purification of solvents by distillation in all-glass systems may be required. Where possible, reagents are cleaned by extraction or solvent rinse.
- 4.2** Proper cleaning of glassware is extremely important, because glassware may not only contaminate the samples but may also remove the analytes of interest by adsorption on the glass surface.
- 4.2.1** Glassware should be rinsed with solvent and washed with a detergent solution as soon after use as is practical. Sonication of glassware containing a detergent

solution for approximately 30 seconds may aid in cleaning. Glassware with removable parts, particularly separatory funnels with fluoropolymer stopcocks, must be disassembled prior to detergent washing.

- 4.2.2** After detergent washing, glassware should be rinsed immediately, first with methanol, then with hot tap water. The tap water rinse is followed by another methanol rinse, then acetone, and then methylene chloride.
 - 4.2.3** Baking of glassware in a kiln or other high temperature furnace (300 - 500°C) may be warranted after particularly dirty samples are encountered. The kiln or furnace should be vented to prevent laboratory contamination by pesticide vapors. Baking should be minimized, as repeated baking of glassware may cause active sites on the glass surface that may irreversibly adsorb pesticides. Volumetric ware should not be baked at high temperature.
 - 4.2.4** After drying and cooling, glassware should be sealed and stored in a clean environment to prevent any accumulation of dust or other contaminants. Store inverted or capped with aluminum foil.
 - 4.2.5** Immediately prior to use, the Soxhlet apparatus should be pre-extracted for approximately 3 hours and the extraction apparatus should be rinsed with the extraction solvent.
- 4.3** All materials used in the analysis must be demonstrated to be free from interferences by running reference matrix method blanks (Section 9.5) initially and with each sample batch (samples started through the extraction process on a given 12-hour shift, to a maximum of 20 samples).
- 4.3.1** The reference matrix must simulate, as closely as possible, the sample matrix under test. Ideally, the reference matrix should not contain the pesticides in detectable amounts, but should contain potential interferents in the concentrations expected to be found in the samples to be analyzed.
 - 4.3.2** When a reference matrix that simulates the sample matrix under test is not available, reagent water (Section 7.6.1) can be used to simulate water samples; playground sand (Section 7.6.2) or white quartz sand (Section 7.3.2) can be used to simulate soils; filter paper (Section 7.6.3) can be used to simulate papers and similar materials; and corn oil (Section 7.6.4) can be used to simulate tissues.
- 4.4** Interferences co-extracted from samples will vary considerably from source to source, depending on the diversity of the site being sampled. Interfering compounds may be present at concentrations several orders of magnitude higher than the pesticides. The most frequently encountered interferences are chlorinated biphenyls, chlorinated and brominated dibenzodioxins and dibenzofurans, methoxy biphenyls, hydroxydiphenyl ethers, benzylphenyl ethers, brominated diphenyl ethers, polynuclear aromatics, and polychlorinated naphthalenes. Because very low levels of pesticides are measured by this Method, elimination of interferences is essential. The cleanup steps given in Section 13

can be used to reduce or eliminate these interferences and thereby permit reliable determination of the pesticides at the levels shown in Table 1.

- 4.5** Each piece of reusable glassware should be numbered to associate that glassware with the processing of a particular sample. This will assist the laboratory in tracking possible sources of contamination for individual samples, identifying glassware associated with highly contaminated samples that may require extra cleaning, and determining when glassware should be discarded.
- 4.6** Organic acids and other substances make it difficult to extract and clean up biosolids (sewage sludge) samples. The exact procedures to be used are dependent on the analytes to be determined. If all analytes in this Method are to be determined, gel permeation chromatography (GPC), the amino-propyl SPE column, and the layered alumina/Florisil column have been found effective. For the organo-chlorine pesticides, sequential extraction with acetonitrile and methylene chloride followed by back extraction with sodium sulfate-saturated water has been found effective. An anthropogenic isolation column (Section 13.6; see Section 7.5.2 for column details), GPC (Section 13.2), high performance liquid chromatography (HPLC; Section 13.5), Florisil (Section 13.7), and alumina (Section 13.8) are additional steps that may be employed to minimize interferences in the sludge matrix.
- 4.7** The natural lipid content of tissue can interfere in the analysis of tissue samples for measurement of pesticides. The lipid contents of different species and portions of tissue can vary widely. Lipids are soluble to varying degrees in various organic solvents and may be present in sufficient quantity to overwhelm the column chromatographic cleanup procedures used for sample extracts. Lipids must be removed by the anthropogenic isolation column procedure in Section 13.6, followed by GPC (Section 13.2).

5.0 Safety

- 5.1** The toxicity or carcinogenicity of each chemical used in this Method has not been precisely determined; however, each compound should be treated as a potential health hazard. Exposure to these compounds should be reduced to the lowest possible level.
 - 5.1.1** Some pesticides, most notably 4,4'-DDT and 4,4'-DDD, have been tentatively classified as known or suspected human or mammalian carcinogens. Pure standards of the pesticides should be handled only by highly trained personnel thoroughly familiar with handling and cautionary procedures and the associated risks.
 - 5.1.2** It is recommended that the laboratory purchase dilute standard solutions of the analytes in this Method. However, if primary solutions are prepared, they must be prepared in a hood, and a NIOSH/MESA approved toxic gas respirator must be worn when high concentrations are handled.

- 5.2** This Method does not address all safety issues associated with its use. The laboratory is responsible for maintaining a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this Method. A reference file of material safety data sheets (MSDSs) should also be made available to all personnel involved in these analyses. It is also suggested that the laboratory perform personal hygiene monitoring of each analyst who uses this Method and that the results of this monitoring be made available to the analyst. Additional information on laboratory safety can be found in References 4-7. The references and bibliography at the end of Reference 6 are particularly comprehensive in dealing with the general subject of laboratory safety.
- 5.3** The pure pesticides and samples suspected to contain high concentrations of these compounds are handled using essentially the same techniques employed in handling radioactive or infectious materials. Well-ventilated, controlled access laboratories are required. Assistance in evaluating the health hazards of particular laboratory conditions may be obtained from certain consulting laboratories and from State Departments of Health or Labor, many of which have an industrial health service. Each laboratory must develop a strict safety program for handling these compounds. The practices in Reference 8 for handling chlorinated dibenzo-*p*-dioxins and dibenzofurans (CDDs/CDFs) are also recommended for handling pesticides.
- 5.3.1** Facility – When finely divided samples (dusts, soils, dry chemicals) are handled, all operations (including removal of samples from sample containers, weighing, transferring, and mixing) should be performed in a glove box demonstrated to be leak tight or in a fume hood demonstrated to have adequate air flow. Gross losses to the laboratory ventilation system must not be allowed. Handling of the dilute solutions normally used in analytical and animal work presents no inhalation hazards except in the case of an accident.
- 5.3.2** Protective equipment – Disposable plastic gloves, apron or lab coat, safety glasses or mask, and a glove box or fume hood adequate for radioactive work should be used. During analytical operations that may give rise to aerosols or dusts, personnel should wear respirators equipped with activated carbon filters. Eye protection (preferably full face shields) must be worn while working with exposed samples or pure analytical standards. Latex gloves are commonly used to reduce exposure of the hands. When handling samples suspected or known to contain high concentrations of the pesticides, an additional set of gloves can also be worn beneath the latex gloves.
- 5.3.3** Training – Workers must be trained in the proper method of removing contaminated gloves and clothing without contacting the exterior surfaces.
- 5.3.4** Personal hygiene – Hands and forearms should be washed thoroughly after each operation involving high concentrations of the pesticides, and before breaks (coffee, lunch, and shift).

- 5.3.5** Confinement – Isolated work areas posted with signs, segregated glassware and tools, and plastic absorbent paper on bench tops will aid in confining contamination.
- 5.3.6** Effluent vapors – The effluent of the sample splitter from the gas chromatograph (GC) and from roughing pumps on the mass spectrometer (MS) should pass through either a column of activated charcoal or be bubbled through a trap containing oil or high-boiling alcohols to condense pesticide vapors.
- 5.3.7** Waste handling – Good technique includes minimizing contaminated waste. Plastic bag liners should be used in waste cans. Janitors and other personnel should be trained in the safe handling of waste.
- 5.3.8** Decontamination
- 5.3.8.1** Decontamination of personnel – Use any mild soap with plenty of scrubbing action.
- 5.3.8.2** Glassware, tools, and surfaces – Chloroethene NU Solvent is a less toxic solvent that should be effective in removing pesticides. Satisfactory cleaning may be accomplished by rinsing with Chloroethene, then washing with any detergent and water. If glassware is first rinsed with solvent, the wash water may be disposed of in the sewer. Given the cost of disposal, it is prudent to minimize solvent wastes.
- 5.3.9** Laundry – Clothing known to be contaminated should be collected in plastic bags. Persons that convey the bags and launder clothing should be advised of the hazard and trained in proper handling. Clothing may be put into a washer without contact if the launderer knows of the potential problem. The washer should be run through a cycle before being used again for other clothing.
- 5.3.10** Wipe tests – A useful method of determining cleanliness of work surfaces and tools is to perform a wipe test of the surface suspected of being contaminated.
- 5.3.10.1** Using a piece of filter paper moistened with Chloroethene or other solvent, wipe an area approximately 10 x 10 cm.
- 5.3.10.2** Extract and analyze the wipe by GC with an electron capture detector (ECD) or by this Method.
- 5.3.10.3** Using the area wiped (e.g., 10 x 10 cm = 0.01 m²), calculate the concentration in µg/m². A concentration less than 1 µg/m² indicates acceptable cleanliness; anything higher warrants further cleaning. More than 100 µg/m² constitutes an acute hazard and requires prompt cleaning before further use of the equipment or work space, and indicates that unacceptable work practices have been employed.

- 5.4** Biosolids samples may contain high concentrations of biohazards, and must be handled with gloves and opened in a hood or biological safety cabinet to prevent exposure. Laboratory staff should know and observe the safety procedures required in a microbiology laboratory that handles pathogenic organisms when handling biosolids samples.

6.0 Apparatus and materials

Note: Brand names, suppliers, and part numbers are for illustration purposes only and no endorsement is implied. Equivalent performance may be achieved using apparatus and materials other than those specified here. Meeting the performance requirements of this Method is the responsibility of the laboratory.

6.1 Sampling equipment for discrete or composite sampling

6.1.1 Sample bottles and caps

6.1.1.1 Liquid samples (waters, sludges and similar materials containing 5 percent solids or less) – Sample bottle, amber glass, 1.1-L minimum, with screw cap.

6.1.1.2 Solid samples (soils, sediments, sludges, paper pulps, filter cake, compost, and similar materials that contain more than 5 percent solids) – Sample bottle, wide mouth, amber glass, 500-mL minimum.

6.1.1.3 If amber bottles are not available, samples must be protected from light.

6.1.1.4 Bottle caps – Threaded to fit sample bottles. Caps must be lined with fluoropolymer.

6.1.1.5 Cleaning

6.1.1.5.1 Bottles are detergent water washed, then solvent rinsed before use.

6.1.1.5.2 Liners are detergent water washed and rinsed with reagent water (Section 7.6.1).

6.1.2 Compositing equipment – Automatic or manual compositing system incorporating glass containers cleaned per bottle cleaning procedure above. Only glass or fluoropolymer tubing must be used. If the sampler uses a peristaltic pump, a minimum length of compressible silicone rubber tubing may be used in the pump only. Before use, the tubing must be thoroughly rinsed with methanol, followed by repeated rinsing with reagent water to minimize sample contamination. An integrating flow meter is used to collect proportional composite samples.

6.2 Equipment for glassware cleaning

Note: *If blanks from bottles or other glassware or with fewer cleaning steps than required in this Method show no detectable pesticide contamination, unnecessary cleaning steps and equipment may be eliminated.*

6.2.1 Laboratory sink with overhead fume hood

6.2.2 Kiln – Capable of reaching 450°C within 2 hours and maintaining 450 - 500°C within $\nabla 10^{\circ}\text{C}$, with temperature controller and safety switch (Cress Manufacturing Co, Santa Fe Springs, CA, B31H, X31TS, or equivalent). See the precautions in Section 4.2.3.

6.2.3 Aluminum foil – solvent rinsed or baked in a kiln. If baked in a kiln, heavy-duty aluminum foil is required, as thinner foil will become brittle and unusable.

6.3 Equipment for sample preparation

6.3.1 Laboratory fume hood of sufficient size to contain the sample preparation equipment listed below.

6.3.2 Glove box (optional)

6.3.3 Tissue homogenizer – VirTis Model 45 Macro homogenizer (American Scientific Products H-3515, or equivalent) with stainless steel Macro-shaft and Turbo-shear blade.

6.3.4 Meat grinder – Hobart, or equivalent, with 3- to 5-mm holes in inner plate.

6.3.5 Equipment for determining percent moisture

6.3.5.1 Oven – Capable of maintaining a temperature of $110 \nabla 5^{\circ}\text{C}$

6.3.5.2 Desiccator

6.3.6 Balances

6.3.6.1 Analytical – Capable of weighing 0.1 mg

6.3.6.2 Top loading – Capable of weighing 10 mg

6.4 Extraction apparatus

6.4.1 Water and solid samples

- 6.4.1.1** pH meter, with combination glass electrode
- 6.4.1.2** pH paper, wide range (Hydrion Papers, or equivalent)
- 6.4.1.3** Graduated cylinder, glass, 1-L capacity and Erlenmeyer Flask, glass, 1-L capacity
- 6.4.1.4** Liquid/liquid extraction – Separatory funnels, 250-, 500-, and 2000-mL, with fluoropolymer stopcocks
- 6.4.1.5** Solid-phase extraction
 - 6.4.1.5.1** 1-L filtration apparatus, including glass funnel, frit support, clamp, adapter, stopper, filtration flask, and vacuum tubing (Figure 4). For wastewater samples, the apparatus should accept 90 or 144 mm disks. For drinking water or other samples containing low solids, smaller disks may be used.
 - 6.4.1.5.2** Vacuum source – Capable of maintaining 25 in. Hg, equipped with shutoff valve and vacuum gauge
 - 6.4.1.5.3** Glass-fiber filter – Whatman GMF 150 (or equivalent), 1 micron pore size, to fit filtration apparatus in Section 6.4.1.5.1
 - 6.4.1.5.4** Solid-phase extraction disk containing octadecyl (C₁₈) bonded silica uniformly enmeshed in an inert matrix – Fisher Scientific 14-378F (or equivalent), to fit filtration apparatus in Section 6.4.1.5.1
- 6.4.1.6** Continuous liquid/liquid extraction (CLLE) – Fluoropolymer or glass connecting joints and stopcocks without lubrication, 1.5-2 L capacity (Hershberg-Wolf Extractor, Cal-Glass, Costa Mesa, California, 1000 mL or 2000 mL, or equivalent)
- 6.4.2** Soxhlet/Dean-Stark (SDS) extractor (Figure 5 and Reference 3) for filters and solid/sludge samples
 - 6.4.2.1** Soxhlet – 50-mm ID, 200-mL capacity with 500-mL flask (Cal-Glass LG-6900, or equivalent, except substitute 500-mL round-bottom flask for 300-mL flat-bottom flask)
 - 6.4.2.2** Thimble – 43 H 123 to fit Soxhlet (Cal-Glass LG-6901-122, or equivalent)
 - 6.4.2.3** Moisture trap – Dean Stark or Barret with fluoropolymer stopcock, to fit Soxhlet

-
- 6.4.2.4** Heating mantle – Hemispherical, to fit 500-mL round-bottom flask (Cal-Glass LG-8801-112, or equivalent)
 - 6.4.2.5** Variable transformer – Powerstat (or equivalent), 110-volt, 10-amp
 - 6.4.3** Beakers – 400- to 500-mL
 - 6.4.4** Spatulas – Stainless steel
 - 6.5** Filtration apparatus
 - 6.5.1** Pyrex glass wool – Solvent-extracted using a Soxhlet or SDS extractor for 3 hours minimum
 - 6.5.2** Glass funnel – 125- to 250-mL
 - 6.5.3** Glass-fiber filter paper – Whatman GF/D (or equivalent), to fit glass funnel in Section 6.5.2.
 - 6.5.4** Drying column – 15- to 20-mm ID Pyrex chromatographic column equipped with coarse-glass frit or glass-wool plug
 - 6.5.5** Buchner funnel – 15-cm
 - 6.5.6** Glass-fiber filter paper for Buchner funnel above
 - 6.5.7** Filtration flasks – glass, 1.5- to 2.0-L, with side arm
 - 6.5.8** Pressure filtration apparatus – Millipore YT30 142 HW, or equivalent
 - 6.6** Centrifuge apparatus
 - 6.6.1** Centrifuge – Capable of rotating 500-mL centrifuge bottles or 15-mL centrifuge tubes at 5,000 rpm minimum
 - 6.6.2** Centrifuge bottles – 500-mL, with screw-caps, to fit centrifuge
 - 6.6.3** Centrifuge tubes – 12- to 15-mL, with screw-caps, to fit centrifuge
 - 6.7** Cleanup apparatus
 - 6.7.1** Automated gel permeation chromatograph (Analytical Biochemical Labs, Inc, Columbia, MO, Model GPC Autoprep 1002, or equivalent)

- 6.7.1.1** Column – 600-700 mm long H 25 mm ID glass, packed with 70 g of 200-400 mesh SX-3 Bio-beads (Bio-Rad Laboratories, Richmond, CA, or equivalent)
- 6.7.1.2** Syringe – 10-mL, with Luer fitting
- 6.7.1.3** Syringe filter holder – stainless steel, and glass-fiber or fluoropolymer filters (Gelman 4310, or equivalent)
- 6.7.1.4** UV detectors – 254-nm, preparative or semi-preparative flow cell (Isco, Inc., Type 6; Schmadzu, 5-mm path length; Beckman-Altex 152W, 8- μ L micro-prep flow cell, 2-mm path; Pharmacia UV-1, 3-mm flow cell; LDC Milton-Roy UV-3, monitor #1203; or equivalent)
- 6.7.2** Reverse-phase high-performance liquid chromatograph (Reference 9)
 - 6.7.2.1** Pump – Perkin-Elmer Series 410, or equivalent
 - 6.7.2.2** Injector – Perkin-Elmer ISS-100 Autosampler, or equivalent
 - 6.7.2.3** 6-Port switching valve – Valco N60, or equivalent
 - 6.7.2.4** Column – Hypercarb, 100 x 4.6 mm, 5 Φ m particle size, Keystone Scientific, or equivalent
 - 6.7.2.5** Detector – Altex 110A (or equivalent) operated at 0.02 AUFS at 235 nm
 - 6.7.2.6** Fraction collector – Isco Foxy II, or equivalent
- 6.7.3** Pipets, precleaned
 - 6.7.3.1** Disposable, Pasteur, 150-mm long x 5-mm ID (Fisher Scientific 13-678-6A, or equivalent)
 - 6.7.3.2** Disposable, serological, 50-mL (8- to 10- mm ID)
- 6.7.4** Glass chromatographic columns
 - 6.7.4.1** 150-mm long x 8-mm ID, (Kontes K-420155, or equivalent) with coarse-glass frit or glass-wool plug and 250-mL reservoir
 - 6.7.4.2** 200-mm long x 15-mm ID, with coarse-glass frit or glass-wool plug and 250-mL reservoir
 - 6.7.4.3** 300-mm long x 22-mm ID, with coarse-glass frit, 300-mL reservoir, and glass or fluoropolymer stopcock

- 6.7.5** Oven – For baking and storage of adsorbents, capable of maintaining a constant temperature (∇ 5°C) in the range of 105-250°C
- 6.7.6** System for solid-phase extraction
 - 6.7.6.1** Vac-Elute Manifold (Analytichem International, or equivalent)
 - 6.7.6.2** Vacuum trap: Made from 500-mL sidearm flask fitted with single-hole rubber stopper and glass tubing
 - 6.7.6.3** Rack for holding 50-mL volumetric flasks in the manifold
- 6.8** Concentration apparatus
 - 6.8.1** Rotary evaporator – Buchi/Brinkman-American Scientific No. E5045-10 or equivalent, equipped with a variable temperature water bath
 - 6.8.1.1** Vacuum source for rotary evaporator equipped with vacuum gauge and with shutoff valve at the evaporator
 - 6.8.1.2** A recirculating water pump and chiller are recommended. Use of tap water for cooling the evaporator wastes large volumes of water and can lead to inconsistent performance as water temperatures and pressures vary.
 - 6.8.1.3** Round-bottom flask – 100-mL and 500-mL or larger, with ground-glass fitting compatible with the rotary evaporator
 - 6.8.2** Kuderna-Danish (K-D) concentrator
 - 6.8.2.1** Concentrator tube – 10-mL, graduated (Kontes K-570050-1025, or equivalent) with calibration verified. Ground-glass stopper (size 19/22 joint) is used to prevent evaporation of extracts.
 - 6.8.2.2** Evaporation flask – 500-mL (Kontes K-570001-0500, or equivalent), attached to concentrator tube with springs (Kontes K-662750-0012 or equivalent)
 - 6.8.2.3** Snyder column – Three-ball macro (Kontes K-503000-0232, or equivalent)

- 6.8.2.4** Boiling chips
 - 6.8.2.4.1** Glass or silicon carbide – Approximately 10/40 mesh, extracted with methylene chloride and baked at 450°C for one hour minimum
 - 6.8.2.4.2** Fluoropolymer (optional) – Extracted with methylene chloride
- 6.8.2.5** Water bath – Heated, with concentric ring cover, capable of maintaining a temperature within ∇ 2°C, installed in a fume hood
- 6.8.3** Nitrogen evaporation apparatus – Equipped with water bath controlled in the range of 30 - 60°C (N-Evap, Organomation Associates, Inc., South Berlin, MA, or equivalent), installed in a fume hood
- 6.8.4** Sample vials
 - 6.8.4.1** Amber glass, 2- to 5-mL with fluoropolymer-lined screw-cap
 - 6.8.4.2** Glass, 0.3-mL, conical, with fluoropolymer-lined screw or crimp cap
- 6.9** Gas chromatograph – Must have splitless or on-column injection port for capillary column, temperature program with isothermal hold, and must meet all of the performance specifications in Section 10.
 - 6.9.1** GC column – 60 ∇ 5-m long x 0.25 ∇ 0.02-mm ID; 0.10- μ m film DB-17, or equivalent
 - 6.9.1.1** The column must meet the following minimum retention time and resolution criteria, and must be adjusted or replaced when these criteria are not met:
 - 6.9.1.1.1** The retention time for methoxychlor must be greater than 39 minutes.
 - 6.9.1.1.2** trans-chlordane and trans-nonachlor (or the labeled analogs) must be uniquely resolved to a valley height less than 10 percent of the shorter of the two peaks.
 - 6.9.1.2** Endrin and DDT breakdown – The column must meet the endrin/DDT breakdown criteria in Section 10.6.2.3. Some GC injectors may be unable to meet requirements for endrin and DDT breakdown. This problem can be minimized by operating the injector at 200 - 205 °C, using a Pyrex (not quartz) methyl silicone deactivated injector liner, and deactivating the injector with dichlorodimethylsilane. A temperature

programmed injector has also been shown to minimize decomposition of labile substances such as endrin and DDT (Reference 10).

- 6.10** Mass spectrometer – 28- to 40-eV electron impact ionization, must be capable of selectively monitoring a minimum of 22 exact m/z's minimum at high resolution (greater than 8,000) during a period less than 1.5 seconds, and must meet all of the performance specifications in Section 10.
- 6.11** GC/MS interface – The mass spectrometer (MS) must be interfaced to the GC such that the end of the capillary column terminates within 1 cm of the ion source but does not intercept the electron or ion beams.
- 6.12** Data system – Capable of collecting, recording, storing, and processing MS data
- 6.12.1** Data acquisition – The signal at each exact m/z must be collected repetitively throughout the monitoring period and stored on a mass storage device.
- 6.12.2** Response factors and multipoint calibrations – The data system must record and maintain lists of response factors (response ratios for isotope dilution) and multipoint calibrations. Computations of relative standard deviation (RSD) are be used to test calibration linearity. Statistics on initial (Section 9.4) and ongoing (Section 15.6.4) performance should be computed and maintained, either on the instrument data system, or on a separate computer system.

7.0 Reagents and standards

7.1 pH adjustment and back-extraction

- 7.1.1** Potassium hydroxide (KOH) – Dissolve 20 g reagent grade KOH in 100 mL reagent water.
- 7.1.2** Sulfuric acid (H₂SO₄) – Reagent grade (specific gravity 1.84)
- 7.1.3** Hydrochloric acid – Reagent grade, 6N
- 7.1.4** Sodium chloride solution – Prepare at 5% (w/v) solution in reagent water
- 7.1.4** Sodium sulfate solution – Prepare at 2% (w/v) in reagent water; pH adjust to 8.5 - 9.0 with KOH or H₂SO₄

7.2 Solution and tissue drying, municipal sludge extract back-extraction, and solvent evaporation (blowdown)

- 7.2.1** Solution drying – Sodium sulfate, reagent grade, granular, anhydrous (Baker 3375, or equivalent), rinsed with methylene chloride (20 mL/g), baked at 400°C for 1 hour minimum, cooled in a desiccator, and stored in a pre-cleaned glass bottle with screw-cap that prevents moisture from entering. If, after heating, the sodium

sulfate develops a noticeable grayish cast (due to the presence of carbon in the crystal matrix), that batch of reagent is not suitable for use and should be discarded. Extraction with methylene chloride (as opposed to simple rinsing) and baking at a lower temperature may produce sodium sulfate that is suitable for use.

- 7.2.2** Tissue drying – Sodium sulfate, reagent grade, powdered, treated and stored as in Section 7.2.1
 - 7.2.3** Solution for back-extraction of municipal sludge extracts – Sodium sulfate solution: 2% (w/v) in reagent water, pH adjusted to pH 8.5 to 9.0 with KOH or H₂SO₄
 - 7.2.4** Prepurified nitrogen
- 7.3** Extraction
- 7.3.1** Solvents – Acetone, toluene, cyclohexane, hexane, methanol, methylene chloride, isooctane, and nonane; distilled in glass, pesticide quality, lot-certified to be free of interferences
 - 7.3.2** White quartz sand, 60/70 mesh – For Soxhlet/Dean-Stark extraction (Aldrich Chemical, Cat. No. 27-437-9, or equivalent). Bake at 450 – 500°C for 4 hours minimum.
- 7.4** GPC calibration solution – Prepare a solution containing 2.5 mg/mL corn oil, 0.05 mg/mL bis(2-ethylhexyl) phthalate (BEHP), 0.01 mg/mL methoxychlor, 0.002 mg/mL perylene, and 0.008 mg/mL sulfur, or at concentrations appropriate to the response of the detector.
- 7.5** Adsorbents for sample cleanup
- 7.5.1** Silica gel
 - 7.5.1.1** Activated silica gel – 100-200 mesh, Supelco 1-3651 (or equivalent), mesh, rinsed with methylene chloride, baked at 180±5 °C for a minimum of 1 hour, cooled in a desiccator, and stored in a precleaned glass bottle with screw-cap that prevents moisture from entering.
 - 7.5.1.1.1** 10% deactivated silica – Place 100 g of activated silica gel (Section 7.5.1.1) in a clean glass bottle or jar and add 10 g (or mL) of reagent water. Cap the bottle tightly to prevent moisture from entering or escaping.
 - 7.5.1.1.2** Tumble the bottle for 5 - 10 hours to thoroughly mix the water and silica. Keep bottle tightly sealed when silica is not being removed for use.

- 7.5.1.2** Acid silica gel (30% w/w) – Thoroughly mix 44 g of concentrated sulfuric acid with 100 g of activated silica gel in a clean container. Break up aggregates with a stirring rod until a uniform mixture is obtained. Store in a screw-capped bottle with fluoropolymer-lined cap.
- 7.5.1.3** Basic silica gel – Thoroughly mix 30 g of 1N sodium hydroxide with 100 g of activated silica gel in a clean container. Break up aggregates with a stirring rod until a uniform mixture is obtained. Store in a screw-capped bottle with fluoropolymer-lined cap.
- 7.5.1.4** Potassium silicate
- 7.5.1.4.1** Dissolve 56 g of high purity potassium hydroxide (Aldrich, or equivalent) in 300 mL of methanol in a 750- to 1000-mL flat-bottom flask.
- 7.5.1.4.2** Add 100 g of activated silica gel (Section 7.5.1.1) and a stirring bar, and stir on an explosion-proof hot plate at 60-70°C for 1-2 hours.
- 7.5.1.4.3** Decant the liquid and rinse the potassium silicate twice with 100-mL portions of methanol, followed by a single rinse with 100 mL of methylene chloride.
- 7.5.1.4.4** Spread the potassium silicate on solvent-rinsed aluminum foil and dry for 2-4 hours in a hood. Observe the precaution in Section 5.3.2.
- 7.5.1.4.5** Activate overnight at 200-250°C prior to use.
- 7.5.2** Anthropogenic isolation column – Pack the column in Section 6.7.4.3 from bottom to top with the following:
- 7.5.2.1** 2 g silica gel (Section 7.5.1.1)
- 7.5.2.2** 2 g potassium silicate (Section 7.5.1.4)
- 7.5.2.3** 2 g granular anhydrous sodium sulfate (Section 7.2.1)
- 7.5.2.4** 10 g acid silica gel (Section 7.5.1.2)
- 7.5.2.5** 2 g granular anhydrous sodium sulfate
- 7.5.3** Aminopropyl solid-phase extraction (SPE) column – 1 g aminopropyl-bonded silica (Varian NH₂, or equivalent).
-

Note: Other SPE columns (e.g., C_{18} octadecyl, cyanopropyl) may be used provided the laboratory establishes the elution conditions and meets the requirements in Section 9.2 with the SPE column as an integral part of the analysis.

7.5.4 Florisil column

- 7.5.4.1** Florisil – PR grade, 60-100 mesh (U.S. Silica Corp, Berkeley Springs, WV, or equivalent). Alternatively, prepacked Florisil columns may be used. Use the following procedure for Florisil activation and column packing.
- 7.5.4.2** Fill a clean 1- to 2-L bottle 1/2 to 2/3 full with Florisil and place in an oven at 130-150°C for a minimum of three days to activate the Florisil.
- 7.5.4.3** Immediately prior to use, dry pack a 300-mm x 22-mm ID glass column (Section 6.7.4.3) bottom to top with 0.5-1.0 cm of warm to hot anhydrous sodium sulfate (Section 7.2.1), 10-10.5 cm of warm to hot activated Florisil (Section 7.5.4.2), and 1-2 cm of warm to hot anhydrous sodium sulfate. Allow the column to cool and pre-elute immediately with 100 mL of n-hexane. Keep column wet with hexane to prevent water from entering.
- 7.5.4.4** Using the procedure in Section 13.7.3, establish the elution pattern for each carton of Florisil or each lot of Florisil columns received.

7.5.5 Alumina column

- 7.5.5.1** Alumina – Neutral, Brockman Activity I, 80-200 mesh (Fisher Scientific Certified, or equivalent). Heat for 16 hours at 400 to 450°C. Seal and cool to room temperature. Add 7% (W/W) reagent water and tumble for 1 to 2 hours. Keep bottle tightly sealed.
- 7.5.5.2** Immediately prior to use, partially fill a 150-mm x 8-mm ID glass column (Section 6.7.4.1) with n-hexane. Pack the column bottom to top with 0.5 - 1 cm of warm to hot anhydrous sodium sulfate (Section 7.2.1), 10 - 10.5 cm alumina (Section 7.5.5.1) and 1 - 1.5 cm of warm to hot anhydrous sodium sulfate. Allow the column to cool and pre-elute immediately with 100 mL of hexane. Keep column wet with hexane to prevent moisture from entering.

7.6 Reference matrices – Matrices in which the pesticides and interfering compounds are not detected by this Method

- 7.6.1** Reagent water – Bottled water purchased locally, or prepared by passage through activated carbon

- 7.6.2** High-solids reference matrix – Playground sand or similar material. Prepared by extraction with methylene chloride and/or baking at 450°C for a minimum of 4 hours.
- 7.6.3** Paper reference matrix – Glass-fiber filter, Gelman type A, or equivalent. Cut paper to simulate the surface area of the paper sample being tested.
- 7.6.4** Tissue reference matrix – Corn or other vegetable oil.
- 7.6.5** Other matrices – This Method may be verified on any reference matrix by performing the tests given in Section 9.2. Ideally, the matrix should be free of the pesticides, but in no case must the background level of the pesticides in the reference matrix exceed the minimum levels in Table 1. If low background levels of the pesticides are present in the reference matrix, the spike level of the analytes used in Section 9.2 should be increased to provide a spike-to-background ratio of approximately 5 (Reference 11).
- 7.7** Standard solutions – Prepare from materials of known purity and composition or purchase as solutions or mixtures with certification to their purity, concentration, and authenticity. If the chemical purity is 98 % or greater, the weight may be used without correction to calculate the concentration of the standard. Observe the safety precautions in Section 5 and the recommendation in Section 5.1.2.
- 7.7.1** For preparation of stock solutions from neat materials, dissolve an appropriate amount of assayed reference material in solvent. For example, weigh 10 to 20 mg of lindane to three significant figures in a 10-mL ground-glass-stoppered volumetric flask and fill to the mark with nonane. After the compound is completely dissolved, transfer the solution to a clean 15-mL vial with fluoropolymer-lined cap.
- 7.7.2** When not being used, store standard solutions in the dark at room temperature in screw-capped vials with fluoropolymer-lined caps. Place a mark on the vial at the level of the solution so that solvent loss by evaporation can be detected. Replace the solution if solvent loss has occurred.
- 7.8** Native (unlabeled) stock solutions
- 7.8.1** Native stock solution – Prepare to contain the pesticides at the concentrations shown in Table 3, or purchase prepared solutions. If additional pesticides are to be determined, include the additional native compounds in this stock solution.
- 7.8.2** Stock solutions should be checked for signs of degradation (e.g., discoloration, precipitation) prior to preparing calibration or performance test standards. Reference standards that can be used to determine the accuracy of standard solutions are available from several vendors.
- 7.9** Labeled compound stock solutions (Table 3)

- 7.9.1** Labeled pesticide stock solution – Prepare the labeled pesticides in isooctane or nonane at the concentrations in Table 3 or purchase prepared standards. If additional pesticides are to be determined by isotope dilution, include the additional labeled compounds in this stock solution.
- 7.9.2** Labeled injection internal standard stock solution – Prepare labeled PCB 52 in nonane or isooctane at the concentration shown in Table 3, or purchase a prepared standard.
- 7.10** Calibration standards – Combine and dilute the solutions in Sections 7.8 and 7.9 to produce the calibration solutions in Table 4 or purchase prepared standards for the CS-1 to CS-6 set of calibration solutions. These solutions permit the relative response (labeled to native) and response factor to be measured as a function of concentration. The CS-4 standard is used for calibration verification (VER).
- 7.11** Native IPR/OPR standard spiking solution – Used for determining initial precision and recovery (IPR; Section 9.2) and ongoing precision and recovery (OPR; Section 15.6). Dilute the Native stock solution (Section 7.8.1) with acetone to produce the concentrations of the pesticides as shown in Table 3. When 1 mL of this solution is spiked into the IPR (Section 9.2.1) or OPR (Section 15.6) and concentrated to a final volume of 20 μ L, the concentration of the pesticides in the final volume will be either 8 or 20 ng/mL (pg/ Φ L), as shown in Table 3. Prepare only the amount necessary for each reference matrix with each sample batch.
- 7.12** Labeled standard spiking solution – This solution is spiked into each sample (Section 9.3) and into the IPR (Section 9.2.1), OPR (Section 15.6), and blank (Section 9.5) to measure recovery. Dilute the Labeled pesticide stock solution (Section 7.9.1) with acetone to produce the concentrations of the labeled compounds shown in Table 3. When 1 mL of this solution is spiked into an IPR, OPR, blank, or sample and concentrated to a final extract volume of 20 μ L, the concentration in the final volume will be as shown in Table 3. Prepare only the amount necessary for each reference matrix with each sample batch.
- 7.13** Endrin/4,4'-DDT breakdown solution – Prepare a solution to contain 100 ng/mL (pg/ μ L) of DDT and 50 ng/mL (pg/ μ L) of endrin in isooctane or nonane. This solution is to determine endrin/4,4'-DDT breakdown in Sections 10.6 and 15.5.
- 7.14** Labeled injection internal standard spiking solution – This solution is added to each concentrated extract prior to injection into the HRGC/HRMS. Dilute the Labeled injection internal standard stock solution (Section 7.9.2) in nonane to produce a concentration of the injection internal standards at 800 ng/mL, as shown in Table 3. When 2 μ L of this solution is spiked into a 20 μ L extract, the concentration of each injection internal standard will be nominally 80 ng/mL (pg/ μ L), as shown in Table 3.

Note: *The addition of 2 μ L of the Labeled injection internal standard spiking solution to a 20 μ L final extract has the effect of diluting the concentration of the components in the extract by 10%.*

Provided all calibration solutions and all extracts undergo this dilution as a result of adding the Labeled injection internal standard spiking solution, the effect of the 10% solution is compensated, and correction for this dilution should not be made.

- 7.15** QC Check Sample – A QC Check Sample should be obtained from a source independent of the calibration standards. Ideally, this check sample would be a certified Standard Reference Material (SRM) containing the pesticides in known concentrations in a sample matrix similar to the matrix under test. The National Institute of Standards and Technology (NIST) in Gaithersburg, Maryland has SRMs, and the Institute for National Measurement Standards of the National Research Council of Canada in Ottawa has certified reference materials (CRMs), for pesticides in various matrices.
- 7.16** Stability of solutions – Standard solutions used for quantitative purposes (Sections 7.8 - 7.14) should be assayed periodically (e.g., every 6 months) against SRMs from NIST (if available), or certified reference materials from a source that will attest to the authenticity and concentration, to assure that the composition and concentrations have not changed.

8.0 Sample collection, preservation, storage, and holding times

- 8.1** Collect samples in amber glass containers following conventional sampling practices (Reference 12); collect field and trip blanks as necessary to validate the sampling.
- 8.2** Aqueous samples
- 8.2.1** Samples that flow freely are collected as grab samples or in refrigerated bottles using automatic sampling equipment. Collect 1-L. If high concentrations of the pesticides are expected, collect a smaller volume (e.g., 100 mL) in addition to the 1-L sample. Do not rinse the bottle with sample before collection.
- 8.2.2** If residual chlorine is present, add 80 mg sodium thiosulfate per liter of water. Any method suitable for field use may be employed to test for residual chlorine (Reference 9).
- 8.2.3** Maintain aqueous samples in the dark at <6°C from the time of collection until receipt at the laboratory (see 40 CFR 136.6(e), Table II). If the sample will be frozen, allow room for expansion.
- 8.2.4** If the sample will not be analyzed within 72 hours, adjust the pH to a range of 5.0 to 9.0 with sodium hydroxide or sulfuric acid solution. Record the volume of acid or base used.
- 8.3** Solid, mixed-phase, semi-solid, and oily samples, excluding tissue.
- 8.3.1** Collect samples as grab samples using wide-mouth jars. Collect a sufficient amount of wet material to produce a minimum of 20 g of solids.

8.3.2 Maintain solid, semi-solid, oily, and mixed-phase samples in the dark at <6°C from the time of collection until receipt at the laboratory. Store solid, semi-solid, oily, and mixed-phase samples in the dark at less than -10°C.

8.4 Fish and other tissue samples

8.4.1 Fish may be cleaned, filleted, or processed in other ways in the field, such that the laboratory may expect to receive whole fish, fish fillets, or other tissues for analysis.

8.4.2 Collect fish, wrap in aluminum foil, and maintain at <6°C from the time of collection until receipt at the laboratory, to a maximum time of 24 hours. If a longer transport time is necessary, freeze the sample. Ideally, fish should be frozen upon collection and shipped to the laboratory under dry ice.

8.4.3 Freeze tissue samples upon receipt at the laboratory and maintain in the dark at less than -10°C until prepared. Maintain unused sample in the dark at less than -10°C.

8.4.4 Store sample extracts in the dark at less than -10°C until analyzed.

8.5 Holding times – See 40 CFR 136.3(e) Table II

8.5.1 Aqueous samples – Extract within 7 days of collection, and analyze within 40 days of extraction.

8.5.2 Solid, mixed-phase, semi-solid, tissue, and oily samples – Extract and analyze within 1 year of collection. If a sample is to be stored for more than 14 days, and results are to be reported in solids units, either hermetically seal the sample container or determine the moisture content upon receipt and immediately prior to analysis. Adjust the final concentration based on the original moisture content.

9.0 Quality assurance/quality control

9.1 Each laboratory that uses this Method is required to operate a formal quality assurance program (Reference 14). The minimum requirements of this program consist of an initial demonstration of laboratory capability, analysis of samples spiked with labeled compounds to evaluate and document data quality, and analysis of standards and blanks as tests of continued performance. Laboratory performance is compared to established performance criteria to determine if the results of analyses meet the performance characteristics of the Method.

If the Method is to be applied to a sample matrix other than water (e.g., soils, filter cake, compost, tissue) the most appropriate alternate reference matrix (Sections 7.6.2 - 7.6.5 and 7.15) is substituted for the reagent water matrix (Section 7.6.1) in all performance tests.

- 9.1.1** The laboratory must make an initial demonstration of the ability to generate acceptable precision and recovery with this Method. This demonstration is given in Section 9.2.
- 9.1.2** In recognition of advances that are occurring in analytical technology, and to overcome matrix interferences, the laboratory is permitted certain options to improve separations or lower the costs of measurements. These options include alternate extraction, concentration, and cleanup procedures, and changes in columns and detectors (see also 40 CFR 136.6). Alternate determinative techniques, such as the substitution of spectroscopic or immuno-assay techniques, and changes that degrade Method performance, are not allowed. If an analytical technique other than the techniques specified in this Method is used, that technique must have a specificity equal to or greater than the specificity of the techniques in this Method for the analytes of interest.
- 9.1.2.1** Each time a modification is made to this Method, the laboratory is required to repeat the procedure in Section 9.2. If the detection limit of the Method will be affected by the change, the laboratory is required to demonstrate that the MDLs (40 CFR Part 136, Appendix B) are lower than one-third the regulatory compliance level or the MDLs in this Method, whichever are greater. If calibration will be affected by the change, the instrument must be recalibrated per Section 10. Once the modification is demonstrated to produce results equivalent or superior to results produced by this Method as written, that modification may be used routinely thereafter, so long as the other requirements in this Method are met (e.g., labeled compound recovery).
- 9.1.2.2** The laboratory is required to maintain records of modifications made to this Method. These records include the following, at a minimum:
- 9.1.2.2.1** The names, titles, addresses, and telephone numbers of the analyst(s) that performed the analyses and modification, and of the quality control officer that witnessed and will verify the analyses and modifications.
- 9.1.2.2.2** A listing of pollutant(s) measured, by name and CAS Registry number.
- 9.1.2.2.3** A narrative stating reason(s) for the modifications.
- 9.1.2.2.4** Results from all quality control (QC) tests comparing the modified method to this Method, including:
- Calibration (Section 10)
 - Calibration verification (Section 15.3)
 - Initial precision and recovery (Section 9.2)
 - Labeled compound recovery (Section 9.3)

- e) Analysis of blanks (Section 9.5)
- f) Accuracy assessment (Section 9.4)

9.1.2.2.5 Data that will allow an independent reviewer to validate each determination by tracing the instrument output (peak height, area, or other signal) to the final result. These data are to include:

- a) Sample numbers and other identifiers
- b) Extraction dates
- c) Analysis dates and times
- d) Analysis sequence/run chronology
- e) Sample weight or volume (Section 11)
- f) Extract volume prior to each cleanup step (Section 13)
- g) Extract volume after each cleanup step (Section 13)
- h) Final extract volume prior to injection (Section 14)
- i) Injection volume (Sections 10.3 and 14.3)
- j) Dilution data, differentiating between dilution of a sample or extract (Section 17.5)
- k) Instrument and operating conditions
- l) Column (dimensions, liquid phase, solid support, film thickness, etc)
- m) Operating conditions (temperatures, temperature program, flow rates)
- n) Detector (type, operating conditions, etc)
- o) Chromatograms, printer tapes, and other recordings of raw data
- p) Quantitation reports, data system outputs, and other data to link the raw data to the results reported

9.1.2.3 Alternate HRGC columns and column systems – If a column or column system alternate to those specified in this Method is used, that column or column system must meet the requirements in Section 6.9.1.

9.1.3 Analyses of method blanks are required to demonstrate freedom from contamination (Section 4.3). The procedures and criteria for analysis of a method blank are given in Sections 9.5 and 15.7.

9.1.4 The laboratory must spike all samples with labeled compounds to monitor Method performance. This test is described in Section 9.3. When results of these spikes indicate atypical Method performance for samples, the samples are diluted to bring Method performance within acceptable limits. Procedures for dilution are given in Section 17.5.

9.1.5 The laboratory must, on an ongoing basis, demonstrate through calibration verification and the analysis of the ongoing precision and recovery standard (OPR) and

blanks that the analytical system is in control. These procedures are given in Sections 15.1 through 15.7.

- 9.1.6** The laboratory should maintain records to define the quality of data generated. Development of accuracy statements is described in Sections 9.4 and 15.6.4.
- 9.2** Initial precision and recovery (IPR) – To establish the ability to generate acceptable precision and recovery, the laboratory must perform the following operations:
- 9.2.1** For low solids (aqueous) samples, extract, concentrate, and analyze four 1-L aliquots of reagent water spiked with 1 mL each of the Native spiking solution (Section 7.11) and the Labeled spiking solution (Section 7.12), according to the procedures in Sections 11 through 18. For an alternate sample matrix, four aliquots of the alternate reference matrix (Sections 7.6.1 - 7.6.5) are used. All sample processing steps that are to be used for processing samples, including preparation (Section 11), extraction (Section 12), and cleanup (Section 13), must be included in this test.
- 9.2.2** Using results of the set of four analyses, compute the average percent recovery (X) of the extracts and the relative standard deviation (RSD) of the concentration for each compound, by isotope dilution for pesticides with a labeled analog, and by internal standard for pesticides without a labeled analog and for the labeled compounds.
- 9.2.3** For each pesticide and labeled compound, compare RSD and X with the corresponding limits for initial precision and recovery in Table 5. If RSD and X for all compounds meet the acceptance criteria, system performance is acceptable and analysis of blanks and samples may begin. If, however, any individual RSD exceeds the precision limit or any individual X falls outside the range for recovery, system performance is unacceptable for that compound. Correct the problem and repeat the test (Section 9.2).
- 9.3** To assess Method performance on the sample matrix, the laboratory must spike all samples with the Labeled spiking solution (Section 7.12).
- 9.3.1** Analyze each sample according to the procedures in Sections 11 through 18.
- 9.3.2** Compute the percent recovery of the labeled pesticides using the internal standard method (Section 17.2).
- 9.3.3** The recovery of each labeled compound must be within the limits in Table 5. If the recovery of any compound falls outside of these limits, Method performance is unacceptable for that compound in that sample. Additional cleanup procedures must then be employed to attempt to bring the recovery within the normal range. If the recovery cannot be brought within the normal range after all cleanup procedures have been employed, water samples are diluted and smaller amounts of soils, sludges, sediments, and other matrices are analyzed per Section 18.

- 9.4** It is suggested but not required that recovery of labeled compounds from samples be assessed and records maintained.
- 9.4.1** After the analysis of 30 samples of a given matrix type (water, soil, sludge, pulp, etc.) for which the labeled compounds pass the tests in Section 9.3, compute the average percent recovery (R) and the standard deviation of the percent recovery (S_R) for the labeled compounds only. Express the assessment as a percent recovery interval from $R - 2S_R$ to $R + 2S_R$ for each matrix. For example, if $R = 90\%$ and $S_R = 10\%$ for five analyses of pulp, the recovery interval is expressed as 70 to 110%.
- 9.4.2** Update the accuracy assessment for each labeled compound in each matrix on a regular basis (e.g., after each five to ten new measurements).
- 9.5** Method blanks – A reference matrix Method blank is analyzed with each sample batch (Section 4.3) to demonstrate freedom from contamination. The matrix for the Method blank must be similar to the sample matrix for the batch, e.g., a 1-L reagent water blank (Section 7.6.1), high-solids reference matrix blank (Section 7.6.2), paper matrix blank (Section 7.6.3); tissue blank (Section 7.6.4), or alternate reference matrix blank (Section 7.6.5).
- 9.5.1** Spike 1.0 mL each of the Labeled spiking solution (Section 7.12) into the Method blank, according to the procedures in Sections 11 through 18. Prepare, extract, clean up, and concentrate the Method blank. Analyze the blank immediately after analysis of the OPR (Section 15.6) to demonstrate freedom from contamination.
- 9.5.2** If any pesticide (Table 1) is found in the blank at greater than the minimum level (Table 1) or one-third the regulatory compliance limit, whichever is greater; or if any potentially interfering compound is found in the blank at the minimum level for each pesticide in Table 1 (assuming a response factor of 1 relative to the quantitation reference in Table 2 for a potentially interfering compound; i.e., a compound not listed in this Method), analysis of samples must be halted until the sample batch is re-extracted and the extracts re-analyzed, and the blank associated with the sample batch shows no evidence of contamination at these levels. All samples must be associated with an uncontaminated Method blank before the results for those samples may be reported or used for permitting or regulatory compliance purposes.
- 9.6** QC Check Sample – Analyze the QC Check Sample (Section 7.15) periodically to assure the accuracy of calibration standards and the overall reliability of the analytical process. It is suggested that the QC Check Sample be analyzed at least quarterly.
- 9.7** The specifications contained in this Method can be met if the apparatus used is calibrated properly and then maintained in a calibrated state. The standards used for calibration (Section 10), calibration verification (Section 15.3), and for initial (Section 9.2) and ongoing (Section 15.6) precision and recovery should be identical, so that the most precise results will be obtained. A GC/HRMS instrument will provide the most reproducible

results if dedicated to the settings and conditions required for determination of pesticides by this Method.

- 9.8** Depending on specific program requirements, field replicates may be collected to determine the precision of the sampling technique, and spiked samples may be required to determine the accuracy of the analysis when the internal standard method is used.

10.0 Calibration

- 10.1** Establish the operating conditions necessary to meet the retention times (RTs) and relative retention times (RRTs) for the pesticides in Table 2.

10.1.1 Suggested operating conditions:

GC conditions

Injector	Split/splitless, 2 min
Carrier gas	Helium @ 200 kPa
Injector temperature	180 - 220°C or temperature programmed
Maximum column temperature	300°C

GC Temperature program

Initial temperature and hold	50°C for 1 minute
Initial ramp	50 - 180°C @ 10°C per minute
Second hold	180°C for 0 minute
Second ramp	180 - 200°C @ 1.5°C per minute
Third hold	200°C for 2 minutes
Third ramp	200 - 295°C @ 6°C per minute
Final hold	295°C for 1 minutes or until methoxychlor elutes
Interface temperature	290°C

Mass spectrometer conditions

Source temperature	250°C
Electron energy	35 eV
Trap current	500 - 900 Φ A
Mass resolution	8000
Detector potential	340 - 400 V

10.1.1.1 All portions of the column that connect the GC to the ion source should remain at or above the interface temperature during analysis to preclude condensation of less volatile compounds.

10.1.1.2 The GC conditions may be optimized for compound separation and sensitivity. Once optimized, the same GC conditions must be used for the analysis of all standards, blanks, IPR and OPR standards, and samples.

10.1.2 Retention time calibration for the native and labeled pesticides

10.1.2.1 Inject the CS-4 calibration standard (Section 7.10 and Table 4). Establish the beginning and ending retention times for the scan descriptors in Table 6. Scan descriptors other than those listed in Table 6 may be used provided the MLs in Table 1 are met. Store the retention time (RT) and relative retention time (RRT) for each compound in the data system.

10.1.2.2 The absolute retention time of methoxychlor must exceed 39 minutes on the DB-17 column; otherwise, the GC temperature program must be adjusted and this test repeated until the minimum retention time criterion is met. If a GC column or column system alternate to the DB-17 column is used, a similar minimum retention time specification must be established for the alternate column or column systems so that interferences that may be encountered in environmental samples will be resolved from the analytes of interest. This specification is deemed to be met if the retention time of methoxychlor is greater than 39 minutes on such alternate column.

10.2 Mass spectrometer (MS) resolution

10.2.1 Using PFK (or other reference substance) and a molecular leak, tune the instrument to meet the minimum required resolving power of 8,000 (10% valley) at m/z 280.9825 or other significant PFK fragment in the range of 250 - 300. For each descriptor (Table 6), monitor and record the resolution and exact m/z 's of three to five reference peaks covering the mass range of the descriptor. The level of PFK (or other reference substance) metered into the HRMS during analyses should be adjusted so that the amplitude of the most intense selected lock-mass m/z signal (regardless of the descriptor number) does not exceed 10% of the full-scale deflection for a given set of detector parameters. Under those conditions, sensitivity changes that might occur during the analysis can be more effectively monitored.

Note: *Different lots and types of PFK can contain varying levels of contamination, and excessive PFK (or other reference substance) may cause noise problems and contamination of the ion source necessitating increased frequency of source cleaning.*

- 10.2.2** The analysis time for the pesticides may exceed the long-term mass stability of the mass spectrometer. Because the instrument is operated in the high-resolution mode, mass drifts of a few ppm (e.g., 5 ppm in mass) can have serious adverse effects on instrument performance. Therefore, mass-drift correction is mandatory and a lock-mass m/z from perfluorokerosene (PFK) or other reference substance is used for drift correction. The lock-mass m/z is dependent on the exact m/z 's monitored within each descriptor, as shown in Table 6. The deviation between each monitored exact m/z and the theoretical m/z (Table 6) must be less than 5 ppm.
- 10.2.3** Obtain a selected ion current profile (SICP) at the two exact m/z 's specified in Table 6 and at $\geq 8,000$ resolving power for each native and labeled pesticide. Because of the extensive mass range covered in each function, it may not be possible to maintain 8,000 resolution throughout the mass range during the function. Therefore, resolution must be $\geq 6,000$ throughout the mass range and must be $\geq 8,000$ in the center of the mass range for each function.
- 10.2.4** If the HRMS has the capability to monitor resolution during the analysis, it is acceptable to terminate the analysis when the resolution falls below the minimum (Section 10.2.1 and 10.2.3) to save re-analysis time.
- 10.3** Ion abundance ratios, minimum levels, and signal-to-noise ratios during calibration. Choose an injection volume of either 1 or 2 μL , consistent with the capability of the HRGC/HRMS instrument. Inject a 1 or 2 μL aliquot of the CS-1 calibration solution (Table 4) using the GC conditions in Section 10.1.1.
- 10.3.1** Measure the SICP areas for each pesticide, and compute the ion abundance ratios at the exact m/z 's specified in Table 6. Compare the computed ratio to the theoretical ratio given in Table 6.
- 10.3.1.1** The exact m/z 's to be monitored in each descriptor are shown in Table 6. Each group or descriptor must be monitored in succession as a function of GC retention time to ensure that the pesticides are detected. Additional m/z 's may be monitored in each descriptor, and the m/z 's may be divided among more than the descriptors listed in Table 6, provided that the laboratory is able to monitor the m/z 's of all pesticides that may elute from the GC in a given RT window.
- 10.3.1.2** The mass spectrometer must be operated in a mass-drift correction mode, using PFK (or other reference substance) to provide lock m/z 's. The lock mass for each group of m/z 's is shown in Table 6. Each lock mass must be monitored and must not vary by more than $\pm 20\%$ throughout its respective retention time window. Variations of lock mass by more than 20% indicate the presence of co-eluting interferences that raise the source pressure and may significantly reduce the sensitivity of the mass spectrometer. Re-injection of another aliquot of the sample extract may not resolve the problem and additional cleanup of the extract may be

required to remove the interference. A lock mass interference or suppression in a retention time region in which pesticides and labeled compounds do not elute may be ignored.

- 10.3.2** All pesticides and labeled compounds in the CS-1 standard must be within the QC limits in Table 6 for their respective ion abundance ratios; otherwise, the mass spectrometer must be adjusted and this test repeated until the m/z ratios fall within the limits specified. If the adjustment alters the resolution of the mass spectrometer, resolution must be verified (Section 10.2.1) prior to repeat of the test.
- 10.3.3** Verify that the HRGC/HRMS instrument meets the minimum levels (MLs) in Table 1. The peaks representing the pesticides and labeled compounds in the CS-1 calibration standard must have signal-to-noise ratios (S/N) ≥ 3 ; otherwise, the mass spectrometer must be adjusted and this test repeated until the minimum levels in Table 1 are met.
- 10.4** Calibration by isotope dilution – Isotope dilution is used for calibration of the native pesticides for which a labeled analog is available. The reference compound for each native compound is its labeled analog, as listed in Table 2. A 6-point calibration encompassing the concentration range is prepared for each native compound.
- 10.4.1** For the pesticides determined by isotope dilution, the relative response (RR) (labeled to native) vs. concentration in the calibration solutions (Table 4) is computed over the calibration range according to the procedures described below. Five calibration points are employed for less-sensitive HRMS instruments (e.g., VG 70); five or six points may be employed for more-sensitive instruments (e.g., Micromass Autospec Ultima).
- 10.4.2** Determine the response of each pesticide relative to its labeled analog using the area responses of both the primary and secondary exact m/z's specified in Table 6, for each calibration standard. Use the labeled compounds listed in Table 2 as the quantitation reference and the two exact m/z's listed in Table 6 for quantitation. The areas at the two exact m/z's for the compound is summed and divided by the summed area of the two exact m/z's for the quantitation reference.

Note: Both exact m/z's are used as reference to reduce the effect of an interference at a single m/z. Other quantitation references and procedures may be used provided that the results produced are as accurate as results produced by the quantitation references and procedures described in this Section.

- 10.4.3** Calibrate the native compounds with a labeled analog using the following equation:

$$RR = \frac{(A_{1_n} + A_{2_n}) C_l}{(A_{1_l} + A_{2_l}) C_n}$$

Where:

A_{1_n} and A_{2_n} = The areas of the primary and secondary m/z's for the pesticide

- A_{1_l} and A_{2_l} = The areas of the primary and secondary m/z's for the labeled compound.
- C_l = The concentration of the labeled compound in the calibration standard (Table 4).
- C_n = The concentration of the native compound in the calibration standard (Table 4).

10.4.4 To calibrate the analytical system by isotope dilution, inject calibration standards CS-2 through CS-6 (Section 7.10 and Table 4) for a less sensitive instrument (e.g. VG 70) or CS-1 through CS-6 for a more sensitive instrument (e.g., Micromass Autospec Ultima). Use a volume identical to the volume chosen in Section 10.3, the procedure in Section 14, and the conditions in Section 10.1.1. Compute and store the relative response (RR) for each pesticide at each concentration. Compute the average (mean) RR and the RSD of the 6 RRs.

10.4.5 Linearity – If the RRs for any pesticide are constant (less than 20% RSD), the average RR may be used for that pesticide; otherwise, the complete calibration curve for that pesticide must be used over the calibration range.

10.5 Calibration by internal standard – Internal standard calibration is applied to determination of the native pesticides for which a labeled compound is not available, and to determination of the labeled compounds for performance tests and intra-laboratory statistics (Sections 9.4 and 15.6.4). The reference compound for each compound is listed in Table 2. For the labeled compounds, calibration is performed at a single concentration using data from the 6 points in the calibration (Section 10.4).

10.5.1 Response factors – Internal standard calibration requires the determination of response factors (RF) defined by the following equation:

$$RF = \frac{(A_{1_s} + A_{2_s}) C_{is}}{(A_{1_{is}} + A_{2_{is}}) C_s}$$

Where:

- A_{1_s} and A_{2_s} = The areas of the primary and secondary m/z's for the pesticide.
- $A_{1_{is}}$ and $A_{2_{is}}$ = The areas of the primary and secondary m/z's for the internal standard.
- C_{is} = The concentration of the internal standard (Table 4).
- C_s = The concentration of the compound in the calibration standard (Table 4).

10.5.2 To calibrate the analytical system for pesticides that do not have a labeled analog, and for the labeled compounds, use the data from the 6-point calibration (Section 10.4.4 and Table 4).

10.5.3 Compute and store the response factor (RF) for all native pesticides that do not have a labeled analog and for the labeled compounds. Use the labeled compounds

listed in Table 2 as the quantitation reference and the two exact m/z's listed in Table 6 for quantitation. For example, the areas at the two exact m/z's for the compound is summed and divided by the summed area of the two exact m/z's for the quantitation reference.

- 10.5.4** Compute and store the response factor (RF) for the labeled compounds using the Labeled injection internal standard as the quantitation reference, as given in Table 2.
- 10.5.5** Linearity – If the RFs for any pesticide are constant (less than 35% RSD), the average RF may be used for that pesticide; otherwise, the complete calibration curve for that pesticide must be used over the calibration range.
- 10.6** Endrin/4,4'-DDT breakdown – This test is run after calibration (Section 10.4 and 10.5) or calibration verification (Section 15.3) to assure that the labile pesticides do not decompose in the GC.
- 10.6.1** Inject the endrin/4,4'-DDT breakdown solution (Section 7.13) using the same volume chosen in Section 10.3.
- 10.6.2** Measure and sum the peak areas for both exact m/z's separately for 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, endrin, endrin aldehyde, and endrin ketone using the calibration data from Section 10.4.
- 10.6.2.1** Add the summed peak areas for endrin aldehyde and endrin ketone and separately add the peak areas for 4,4'-DDD and 4,4'-DDE.
- 10.6.2.2** Calculate the endrin and 4,4'-DDT breakdown as follows:
- $$\text{Endrin breakdown (percent)} = \frac{(\text{areas for endrin aldehyde} + \text{endrin ketone})}{\text{areas for endrin}} \times 100$$
- $$4,4\text{'-DDT breakdown (percent)} = \frac{(\text{areas for } 4,4\text{'-DDD} + 4,4\text{'-DDE})}{\text{areas for } 4,4\text{'-DDT}} \times 100$$
- 10.6.2.3** If the breakdown of endrin or 4,4'-DDT exceeds 20 percent, endrin or 4,4'-DDT is decomposing. If decomposition greater than 20 percent of either endrin or 4,4'-DDT occurs, clean and recondition the injector, break off a short section of the inlet end of the column, or alter the GC conditions to reduce the decomposition to where the 20 percent criterion is met (see Section 6.9.1.2).

11.0 Sample preparation

- 11.1** Sample preparation involves modifying the physical form of the sample so that the pesticides can be extracted efficiently. In general, the samples must be in a liquid form or

in the form of finely divided solids in order for efficient extraction to take place. Table 7 lists the phases and suggested quantities for extraction of various sample matrices.

For samples known or expected to contain high levels of the pesticides, the smallest sample size representative of the entire sample should be used (see Section 18). For all samples, the blank and IPR/OPR aliquots must be processed through the same steps as the sample to check for contamination and losses in the preparation processes.

- 11.1.1** For samples that contain particles, percent solids and particle size are determined using the procedures in Sections 11.2 and 11.3, respectively.
- 11.1.2** Aqueous samples – Because the pesticides may be bound to suspended particles, the preparation of aqueous samples is dependent on the solids content of the sample.
 - 11.1.2.1** Aqueous samples containing one percent solids or less are prepared per Section 11.4 and extracted directly using one of the extraction techniques in Section 12.2.
 - 11.1.2.2** For aqueous samples containing greater than one percent solids, a sample aliquot sufficient to provide 10 g of dry solids is used, as described in Section 11.5.
- 11.1.3** Solid Samples - Solid samples are prepared using the procedure described in Section 11.5 followed by extraction using the SDS procedure in Section 12.3.
- 11.1.4** Multi-phase samples – The phase(s) containing the pesticides is separated from the non-pesticide phase using pressure filtration and centrifugation, as described in Section 11.6. The pesticides will be in the organic phase in a multi-phase sample in which an organic phase exists.
- 11.1.5** Procedures for grinding, homogenization, and blending of various sample phases are given in Section 11.7.
- 11.1.6** Tissue samples – Preparation procedures for fish and other tissues are given in Section 11.8.

11.2 Determination of percent suspended solids

Note: *This aliquot is used for determining the solids content of the sample, not for pesticide determination.*

- 11.2.1** Aqueous liquids and multi-phase samples consisting of mainly an aqueous phase.
 - 11.2.1.1** Desiccate and weigh a GF/D filter (Section 6.5.3) to three significant figures.

11.2.1.2 Filter 10.0 \pm 0.02 mL of well-mixed sample through the filter.

11.2.1.3 Dry the filter a minimum of 12 hours at 110 \pm 5°C and cool in a desiccator.

11.2.1.4 Calculate percent solids as follows:

$$\% \text{ Solids} = \frac{\text{Weight of sample aliquot after drying (g)} - \text{weight of filter (g)}}{10 \text{ g}} \times 100$$

11.2.2 Non-aqueous liquids, solids, semi-solid samples, and multi-phase samples in which the main phase is not aqueous; but not tissues.

11.2.2.1 Weigh 5 to 10 g of sample to three significant figures in a tared beaker.

11.2.2.2 Dry a minimum of 12 hours at 110 \pm 5°C, and cool in a desiccator.

11.2.2.3 Calculate percent solids as follows:

$$\% \text{ Solids} = \frac{\text{Weight of sample aliquot after drying}}{\text{Weight of sample aliquot before drying}} \times 100$$

11.3 Estimation of particle size

11.3.1 Spread the dried sample from Section 11.2.1.3 or 11.2.2.2 on a piece of filter paper or aluminum foil in a fume hood or glove box.

11.3.2 Estimate the size of the particles in the sample. If the size of the largest particles is greater than 1 mm, the particle size must be reduced to 1 mm or less prior to extraction using the procedures in Section 11.7.

11.4 Preparation of aqueous samples containing one percent suspended solids or less.

11.4.1 Aqueous samples containing one percent suspended solids or less are prepared using the procedure below and extracted using the one of the extraction techniques in Section 12.2.

11.4.2 Preparation of sample and QC aliquots

11.4.2.1 Mark the original level of the sample on the sample bottle for reference. Weigh the sample plus bottle to \pm 1 g.

11.4.2.2 Spike 1.0 mL of the Labeled pesticide spiking solution (Section 7.12) into the sample bottle. Cap the bottle and mix the sample by shaking. Allow the sample to equilibrate for 1 to 2 hours, with occasional shaking.

- 11.4.2.3** For each sample or sample batch (to a maximum of 20 samples) to be extracted during the same 12-hour shift, place two 1.0-L aliquots of reagent water in clean sample bottles or flasks.
- 11.4.2.4** Spike 1.0 mL of the Labeled pesticide spiking solution (Section 7.12) into both reagent water aliquots. One of these aliquots will serve as the Method blank.
- 11.4.2.5** Spike 1.0 mL of the Native pesticide spiking solution (Section 7.11) into the remaining reagent water aliquot. This aliquot will serve as the OPR (Section 15.6).
- 11.4.2.6** For extraction using SPE, add 5 mL of methanol to the sample and QC aliquots. Cap and shake the sample and QC aliquots to mix thoroughly, and proceed to Section 12.2 for extraction.

11.5 Preparation of samples containing greater than one percent solids.

- 11.5.1** Weigh a well-mixed aliquot of each sample (of the same matrix type) sufficient to provide 10 g of dry solids (based on the solids determination in Section 11.2) into a clean beaker or glass jar, to a maximum of 1 L of sample.
- 11.5.2** Spike 1.0 mL of the Labeled pesticide spiking solution (Section 7.12) into the sample.
- 11.5.3** Prepare the blank and OPR aliquots per Sections 11.4.2.3 - 11.4.2.5.
- 11.5.4** Stir or tumble and equilibrate the aliquots for 1 to 2 hours.
- 11.5.5** Decant excess water. If necessary to remove water, filter the sample through a glass-fiber filter and discard the aqueous liquid.
- 11.5.6** If particles >1 mm are present in the sample (as determined in Section 11.3.2), spread the sample on clean aluminum foil in a hood. After the sample is dry, grind to reduce the particle size (Section 11.7).
- 11.5.7** Extract the sample and QC aliquots using the SDS procedure in Section 12.3.1.

11.6 Multi-phase samples, including high solids municipal sludge samples

- 11.6.1** Using the percent solids determined in Section 11.2.1.4 or 11.2.2.3, determine the volume of sample that will provide 10 g of solids, up to 1 L of sample.
- 11.6.2** Spike 1.0 mL of the Labeled pesticide spiking solution (Section 7.12) into the amount of sample determined in Section 11.6.1, and into the OPR and blank.

- 11.6.3** Prepare the blank and OPR aliquots per Sections 11.4.2.3 - 11.4.2.5.
- 11.6.4** Pressure filter the sample, blank, and OPR through Whatman GF/D glass-fiber filter paper (Section 6.5.3). If necessary to separate the phases and/or settle the solids, centrifuge these aliquots prior to filtration. Discard any aqueous phase (if present). Remove any non-aqueous liquid present and reserve the maximum amount filtered from the sample (Section 11.5.5) or 10 g, whichever is less, for combination with the solid phase (Section 12.3.1.5).
- 11.6.5** If particles >1 mm are present in the sample (as determined in Section 11.3.2) and the sample is capable of being dried, spread the sample and QC aliquots on clean aluminum foil in a hood. Observe the precaution in Section 5.3.1.
- 11.6.6** After the aliquots are dry or if the sample cannot be dried, reduce the particle size using the procedures in Section 11.7 and extract the reduced-size particles using the SDS procedure in Section 12.3. If particles >1 mm are not present, extract the particles and filter in the sample and QC aliquots directly using the SDS procedure in Section 12.3.
- 11.7** Sample grinding, homogenization, or blending – Samples with particle sizes greater than 1 mm (as determined in Section 11.3.2) are subjected to grinding, homogenization, or blending. The method of reducing particle size to less than 1 mm is matrix-dependent. In general, hard particles can be reduced by grinding with a mortar and pestle. Softer particles can be reduced by grinding in a Wiley mill or meat grinder, by homogenization, or in a blender.
- 11.7.1** Each size-reducing preparation procedure on each matrix must be verified by running the tests in Section 9.2 before the procedure is employed routinely.
- 11.7.2** The grinding, homogenization, or blending procedures must be carried out in a glove box or fume hood to prevent particles from contaminating the work environment.
- 11.7.3** Grinding – Certain papers and pulps, slurries, and amorphous solids can be ground in a Wiley mill or heavy duty meat grinder. In some cases, reducing the temperature of the sample to freezing or to dry ice or liquid nitrogen temperatures can aid in the grinding process. Grind the sample aliquots from Sections 11.5.7 or 11.6.6 in a clean grinder. Do not allow the sample temperature to exceed 50°C. Grind the blank and reference matrix aliquots using a clean grinder.
- 11.7.4** Homogenization or blending – Particles that are not ground effectively, or particles greater than 1 mm in size after grinding, can often be reduced in size by high speed homogenization or blending. Homogenize and/or blend the particles or filter from Sections 11.5.7 or 11.6.6 for the sample, blank, and OPR aliquots.
- 11.7.5** Extract the aliquots using the SDS procedure in Section 12.3.1.

11.8 Fish and other tissues – Prior to processing tissue samples, the laboratory must determine the exact tissue to be analyzed. Common requests for analysis of fish tissue include whole fish-skin on, whole fish-skin removed, edible fish fillets (filleted in the field or by the laboratory), specific organs, and other portions. Once the appropriate tissue has been determined, the sample must be homogenized.

11.8.1 Tissue homogenization

11.8.1.1 Samples are homogenized while still frozen, where practical. If the laboratory must dissect the whole fish to obtain the appropriate tissue for analysis, the unused tissues may be rapidly refrozen and stored in a clean glass jar for subsequent use.

11.8.1.2 Each analysis requires 10 g of tissue (wet weight). Therefore, the laboratory should homogenize at least 20 g of tissue to allow for re-extraction of a second aliquot of the same homogenized sample, if re-analysis is required. When whole fish analysis is necessary, the entire fish is homogenized.

11.8.1.3 Homogenize the sample in a tissue homogenizer (Section 6.3.3) or grind in a meat grinder (Section 6.3.4). Cut tissue too large to feed into the grinder into smaller pieces. To assure homogeneity, grind three times.

11.8.1.4 Transfer approximately 10 g (wet weight) of homogenized tissue to a clean, tared, 400- to 500-mL beaker.

11.8.1.5 Transfer the remaining homogenized tissue to a clean jar with a fluoropolymer-lined lid. Seal the jar and store the tissue at less than -10°C. Return any tissue that was not homogenized to its original container and store at less than -10°C.

11.8.2 Tissue QC aliquots

11.8.2.1 Prepare a Method blank by adding approximately 1-2 g of the oily liquid reference matrix (Section 7.6.4) to a 400- to 500-mL beaker. Record the weight to the nearest 10 mg.

11.8.2.2 Prepare an ongoing precision and recovery aliquot by adding 1-2 g of the oily liquid reference matrix (Section 7.6.4) to a separate 400- to 500-mL beaker. Record the weight to the nearest 10 mg.

11.8.3 Spiking

11.8.3.1 Spike 1.0 mL of the Labeled pesticide spiking solution (Section 7.12) into the sample, blank, and OPR aliquot.

11.8.3.2 Spike 1.0 mL of the Native spiking solution (Section 7.11) into the OPR aliquot.

11.8.4 Extract the aliquots using the Soxhlet procedure in Section 12.4.

12.0 Extraction and concentration

12.1 Extraction procedures include: solid phase (Section 12.2.1), separatory funnel (Section 12.2.2), or continuous liquid/liquid (Section 12.2.3) for aqueous liquids; Soxhlet/Dean-Stark (Section 12.3.1) for sludge, solids and filters; and Soxhlet extraction (Section 12.4) for tissues.

Macro-concentration procedures include: rotary evaporation (Section 12.6.1), heating mantle (Section 12.6.2), and Kuderna-Danish (K-D) evaporation (Section 12.6.3). Micro-concentration uses nitrogen evaporation (Section 12.7).

12.2 Extraction of aqueous liquids – separatory or continuous liquid/liquid extraction.

12.2.1 Solid-phase extraction of samples containing less than one percent solids

12.2.1.1 Disk preparation

12.2.1.1.1 Remove the test tube from the suction flask (Figure 4). Place an SPE disk on the base of the filter holder and wet with methylene chloride. While holding a GMF 150 filter above the SPE disk with tweezers, wet the filter with methylene chloride and lay the filter on the SPE disk, making sure that air is not trapped between the filter and disk. Clamp the filter and SPE disk between the 1-L glass reservoir and the vacuum filtration flask.

12.2.1.1.2 Rinse the sides of the reservoir with approx 15 mL of methylene chloride using a squeeze bottle or pipet. Apply vacuum momentarily until a few drops appear at the drip tip. Release the vacuum and allow the filter/disk to soak for approx one minute. Apply vacuum and draw all of the methylene chloride through the filter/disk. Repeat the wash step with approx 15 mL of acetone and allow the filter/disk to air dry.

12.2.1.2 Sample extraction

12.2.1.2.1 Pre-wet the disk by adding approx 20 mL of methanol to the reservoir. Pull most of the methanol through the filter/disk, retaining a layer of methanol approx 2 mm

thick on the filter. Do not allow the filter/disk to go dry from this point until the extraction is completed.

- 12.2.1.2.2** Add approx 20 mL of reagent water to the reservoir and pull most through, leaving a layer approx 2 mm thick on the filter/disk.
- 12.2.1.2.3** Allow the sample (Section 11.4.2.6) to stand for 1-2 hours, if necessary, to settle the suspended particles. Decant the clear layer of the sample, the blank (Section 11.4.2.4), or IPR/OPR aliquot (Section 11.4.2.5) into its respective reservoir and turn on the vacuum to begin the extraction. Adjust the vacuum to complete the extraction in no less than 10 minutes. For samples containing a high concentration of particles (suspended solids), the extraction time may be an hour or longer.
- 12.2.1.2.4** Before all of the sample has been pulled through the filter/disk, add approx 50 mL of reagent water to the sample bottle, swirl to suspend the solids (if present), and pour into the reservoir. Pull through the filter/disk. Use additional reagent water rinses until all solids are removed.
- 12.2.1.2.5** Before all of the sample and rinses have been pulled through the filter/disk, rinse the sides of the reservoir with small portions of reagent water.
- 12.2.1.2.6** Partially dry the filter/disk under vacuum for approx 3 minutes.

12.2.1.3 Elution of the filter/disk

- 12.2.1.3.1** Release the vacuum, remove the entire filter/disk/reservoir assembly from the vacuum flask, and empty the flask. Insert a test tube for eluant collection into the flask. The test tube should have sufficient capacity to contain the total volume of the elution solvent (approx 50 mL) and should fit around the drip tip. The drip tip should protrude into the test tube to preclude loss of sample from spattering when vacuum is applied (see Figure 4). Re-assemble the filter/disk/reservoir assembly on the vacuum flask.
- 12.2.1.3.2** Wet the filter/disk with 4-5 mL of acetone. Allow the acetone to spread evenly across the disk and soak for 15-20 seconds. Pull the acetone through the disk, releasing the vacuum when approx 1 mm thickness remains on the filter.
- 12.2.1.3.3** Rinse the sample bottle with approx 20 mL of methylene chloride and transfer to the reservoir. Pull approx half of the solvent through the filter/disk and release the vacuum. Allow the filter/disk to soak for approx 1 minute. Pull all of the solvent through the disk. Repeat the bottle rinsing and elution step with another 20 mL of methylene chloride. Pull all of the solvent through the disk.
- 12.2.1.3.4** Release the vacuum, remove the filter/disk/reservoir assembly, and remove the test tube containing the sample solution. Quantitatively transfer the solution to a 250-mL separatory funnel and proceed to Section 12.5 for back-extraction.

12.2.2 Separatory funnel extraction

- 12.2.2.1** Pour the spiked sample (Section 11.4.2.2) into a 2-L separatory funnel. Rinse the bottle or flask twice with 5 mL of reagent water and add these rinses to the separatory funnel.
- 12.2.2.2** Add 100 mL methylene chloride to the empty sample bottle. Cap the bottle and shake 60 seconds to rinse the inner surface. Transfer the solvent to the separatory funnel, and extract the sample by shaking the funnel for 2 minutes with periodic venting. Allow the organic layer to separate from the aqueous phase for a minimum of 10 minutes. If an emulsion forms and is more than one-third the volume of the solvent layer, employ mechanical techniques to complete the phase separation

(see note below). Drain the methylene chloride extract through a solvent-rinsed glass funnel and dry over anhydrous sodium sulfate (Section 7.2.1) into an Erlenmeyer flask (1 L).

Note: *If an emulsion forms, the laboratory must employ mechanical techniques to complete the phase separation. The optimum technique depends upon the sample, but may include stirring, filtration through glass wool, use of phase separation paper, centrifugation, use of an ultrasonic bath with ice, addition of NaCl, or other physical methods. Alternatively, solid-phase (Section 12.2.1), CLLE (Section 12.2.3), or other extraction techniques may be used to prevent emulsion formation. Any alternative technique is acceptable so long as the requirements in Section 9.2 are met.*

12.2.2.3 Extract the water sample two more times with 100-mL portions of methylene chloride. Dry each portion over anhydrous sodium sulfate. After the third extraction, rinse the separatory funnel with at least 20 mL of methylene chloride, and add to the three 100-mL portions of methylene chloride. Repeat this rinse at least twice. Allow the methylene chloride extract to dry for 30 min. Transfer to a solvent-rinsed concentration device (Section 12.6).

12.2.2.4 Add 1 mL of a toluene "keeper" to the extract and concentrate using one of the macro-concentration procedures in Section 12.6, then proceed to back extraction in Section 12.5.

12.2.3 Continuous liquid/liquid extraction

12.2.3.1 Place 100-150 mL methylene chloride in each continuous extractor and 200-300 mL in each distilling flask.

12.2.3.2 Pour the sample(s), blank, and QC aliquots into the extractors. Rinse the sample containers with 50-100 mL methylene chloride and add to the respective extractors. Include all solids in the extraction process.

12.2.3.3 Begin the extraction by heating the flask until the methylene chloride is boiling. When properly adjusted, 1-2 drops of methylene chloride per second will fall from the condenser tip into the water. Extract for 16-24 hours.

12.2.3.4 Remove the distilling flask, estimate and record the volume of extract (to the nearest 100 mL), and pour the contents through a drying column containing 7 to 10 cm of granular anhydrous sodium sulfate into the concentration flask. Rinse the distilling flask with 30-50 mL of methylene chloride and pour through the drying column.

12.2.3.5 Add 1 mL of a toluene "keeper" to the extract and concentrate using one of the macro-concentration procedures in Section 12.6, then proceed to back extraction in Section 12.5.

12.3 Extraction of solids – Solid or sludge samples are extracted using a Soxhlet/Dean-Stark extractor (Section 12.3.1).

12.3.1 Soxhlet/Dean-Stark extraction

- 12.3.1.1** Charge a clean extraction thimble (Section 6.4.2.2) with 5.0 g of 100/200 mesh silica (Section 7.5.1.1) topped with 100 g of quartz sand (Section 7.3.2). Do not disturb the silica layer throughout the extraction process.
- 12.3.1.2** Place the thimble in a clean extractor. Place 30 to 40 mL of toluene in the receiver and 200 to 250 mL of toluene in the flask.
- 12.3.1.3** Pre-extract the glassware by heating the flask until the toluene is boiling. When properly adjusted, 1 to 2 drops of toluene will fall per second from the condenser tip into the receiver. Extract the apparatus for a minimum of 3 hours.
- 12.3.1.4** After pre-extraction, cool and disassemble the apparatus. Rinse the thimble with toluene and allow to air dry.
- 12.3.1.5** Load the wet sample and/or filter from Sections 11.5.7, 11.6.6, or 11.7.5 and any non-aqueous liquid from Section 11.6.4 into the thimble and manually mix into the sand layer with a clean metal spatula, carefully breaking up any large lumps of sample.
- 12.3.1.6** Reassemble the pre-extracted SDS apparatus, and add a fresh charge of 300 mL 80:20 toluene:acetone to the receiver and reflux flask. Apply power to the heating mantle to begin re-fluxing. Adjust the reflux rate to match the rate of percolation through the sand and silica beds until water removal lessens the restriction to toluene flow. Frequently check the apparatus for foaming during the first 2 hours of extraction. If foaming occurs, reduce the reflux rate until foaming subsides. Soxhlet extract for 12-24 hours.
- 12.3.1.7** Drain the water from the receiver at 1-2 hours and 8-9 hours, or sooner if the receiver fills with water. After 12-24 hours cool and disassemble the apparatus. Record the total volume of water collected.
- 12.3.1.8** Remove the distilling flask. Drain the water from the receiver and add any toluene in the receiver to the extract in the flask.
- 12.3.1.9** Concentrate the extracts from particles to approximately 10 mL using the rotary evaporator (Section 12.6.1) or heating mantle (Section 12.6.2), transfer to a 250-mL separatory funnel, and proceed with back-extraction (Section 12.5).

12.4 Soxhlet extraction of tissue

Note: *This procedure includes determination of the lipid content of the sample (Section 12.4.9), using the same sample extract that is analyzed by GC/HRMS. Alternatively, a separate sample aliquot may be used for the lipid determination. If a separate aliquot is used for GC/HRMS determination, use nitrogen to evaporate the main portion of the sample extract only to the extent necessary to effect the solvent exchange to n-hexane, so that loss of low molecular weight pesticides is avoided, i.e., it is not necessary to dry the main portion of the sample to constant weight (Section 12.4.8).*

- 12.4.1** Add 30 to 40 g of powdered anhydrous sodium sulfate (Section 7.2.2) to each of the beakers (Section 11.8.4) and mix thoroughly. Cover the beakers with aluminum foil and dry until the mixture becomes a free-flowing powder (30 minutes minimum). Remix prior to extraction to prevent clumping.
- 12.4.2** Assemble and pre-extract the Soxhlet apparatus per Sections 12.3.1-12.3.1.4, except use methylene chloride for the pre-extraction and rinsing and omit the quartz sand.
- 12.4.3** Re-assemble the pre-extracted Soxhlet apparatus and add a fresh charge of methylene chloride to the reflux flask.
- 12.4.4** Transfer the sample/sodium sulfate mixture (Section 12.4.1) to the Soxhlet thimble, and install the thimble in the Soxhlet apparatus.
- 12.4.5** Rinse the beaker with several portions of solvent and add to the thimble. Fill the thimble/receiver with solvent. Extract for 18-24 hours.
- 12.4.6** After extraction, cool and disassemble the apparatus.
- 12.4.7** Quantitatively transfer the extract to a macro-concentration device (Section 12.6) and concentrate to near dryness. Set aside the concentration apparatus for re-use.
- 12.4.8** Complete the removal of the solvent using the nitrogen blowdown procedure (Section 12.7) and a water bath temperature of 60°C. Weigh the receiver, record the weight, and return the receiver to the blowdown apparatus, concentrating the residue until a constant weight is obtained.
- 12.4.9** Percent lipid determination
- 12.4.9.1** Re-dissolve the residue in the receiver in hexane.
- 12.4.9.2** Transfer the residue/hexane to the anthropogenic isolation column (Section 13.6); retaining the boiling chips in the concentration apparatus. Use several rinses to assure that all material is transferred. If necessary, sonicate or heat the receiver slightly to assure that all

material is re-dissolved. Allow the receiver to dry. Weigh the receiver and boiling chips.

- 12.4.9.3** Calculate the lipid content to the nearest three significant figures as follows:

$$\text{Percent lipid} = \frac{\text{Weight of residue (g)}}{\text{Weight of tissue (g)}} \times 100$$

- 12.4.9.4** The laboratory should determine the lipid content of the blank, IPR, and OPR to assure that the extraction system is working effectively.

12.5 Back-extraction with base and acid

Note: *Some pesticides may be decomposed by acid or base. If acid or base back-extraction is employed, the laboratory must evaluate the strengths of the acid and base solutions, and the exposure times, to preclude decomposition.*

- 12.5.1** Back-extraction may not be necessary for some samples, and back-extraction with strong acid and/or base with long contact times may destroy some pesticides. For some samples, the presence of color in the extract may indicate that back-extraction is necessary. If back-extraction is not necessary, concentrate the extract for cleanup or analysis (Section 12.6 and/or 12.7). If back-extraction is necessary, back-extract the extracts from Section 12.2.3.5 or 12.3.1.9 as follows:

- 12.5.2** Back-extract each extract three times sequentially with 500 mL of the aqueous sodium sulfate solution (Section 7.1.5), returning the bottom (organic) layer to the separatory funnel the first two times while discarding the top (aqueous) layer. On the final back-extraction, filter each pesticide extract through a prerinsed drying column containing 7 to 10 cm anhydrous sodium sulfate into a 500- to 1000-mL graduated cylinder. Record the final extract volume. Re-concentrate the sample and QC aliquots per Sections 12.6-12.7, and clean up the samples and QC aliquots per Section 13.

- 12.6** Macro-concentration – Extracts in toluene are concentrated using a rotary evaporator or a heating mantle; extracts in methylene chloride or hexane are concentrated using a rotary evaporator, heating mantle, or Kuderna-Danish apparatus.

Note: *In the concentration procedures below, the extract must not be allowed to concentrate to dryness because low molecular weight pesticides may be totally or partially lost. It may be advantageous to add 1 mL of toluene as a "keeper" to prevent loss of the low molecular weight pesticides.*

- 12.6.1** Rotary evaporation – Concentrate the extracts in separate round-bottom flasks.

- 12.6.1.1** Assemble the rotary evaporator according to manufacturer's instructions, and warm the water bath to 45°C. On a daily basis, pre-

clean the rotary evaporator by concentrating 100 mL of clean extraction solvent through the system. Archive both the concentrated solvent and the solvent in the catch flask for a contamination check if necessary. Between samples, three 2- to 3- mL aliquots of solvent should be rinsed down the feed tube into a waste beaker.

- 12.6.1.2** Attach the round-bottom flask containing the sample extract to the rotary evaporator. Slowly apply vacuum to the system, and begin rotating the sample flask.
- 12.6.1.3** Lower the flask into the water bath, and adjust the speed of rotation and the temperature as required to complete concentration in 15 to 20 minutes. At the proper rate of concentration, the flow of solvent into the receiving flask will be steady, but no bumping or visible boiling of the extract will occur.

Note: *If the rate of concentration is too fast, analyte loss may occur.*

- 12.6.1.4** When the liquid in the concentration flask has reached an apparent volume of approximately 2 mL, remove the flask from the water bath and stop the rotation. Slowly and carefully admit air into the system. Be sure not to open the valve so quickly that the sample is blown out of the flask. Rinse the feed tube with approximately 2 mL of solvent.
 - 12.6.1.5** Proceed to Section 12.5 for back-extraction or Section 12.7 for micro-concentration and solvent exchange.
- 12.6.2** Heating mantle – Concentrate the extracts in separate round-bottom flasks.
- 12.6.2.1** Add one or two clean boiling chips to the round-bottom flask, and attach a three-ball macro Snyder column. Prewet the column by adding approximately 1 mL of solvent through the top. Place the round-bottom flask in a heating mantle, and apply heat as required to complete the concentration in 15 to 20 minutes. At the proper rate of distillation, the balls of the column will actively chatter, but the chambers will not flood.
 - 12.6.2.2** When the liquid has reached an apparent volume of approximately 10 mL, remove the round-bottom flask from the heating mantle and allow the solvent to drain and cool for at least 10 minutes. Remove the Snyder column and rinse the glass joint into the receiver with small portions of solvent.
 - 12.6.2.3** Proceed to Section 12.6 for preparation for back-extraction or Section 12.7 for micro-concentration and solvent exchange.

- 12.6.3** Kuderna-Danish (K-D) – Concentrate the extracts in separate 500-mL K-D flasks equipped with 10-mL concentrator tubes. The K-D technique is used for solvents such as methylene chloride and hexane. Toluene is difficult to concentrate using the K-D technique unless a water bath fed by a steam generator is used.
- 12.6.3.1** Add 1 to 2 clean boiling chips to the receiver. Attach a three-ball macro Snyder column. Prewet the column by adding approximately 1 mL of solvent through the top. Place the K-D apparatus in a hot water bath so that the entire lower rounded surface of the flask is bathed with steam.
- 12.6.3.2** Adjust the vertical position of the apparatus and the water temperature as required to complete the concentration in 15 to 20 minutes. At the proper rate of distillation, the balls of the column will actively chatter but the chambers will not flood.
- 12.6.3.3** When the liquid has reached an apparent volume of 1 mL, remove the K-D apparatus from the bath and allow the solvent to drain and cool for at least 10 minutes. Remove the Snyder column and rinse the flask and its lower joint into the concentrator tube with 1 to 2 mL of solvent. A 5-mL syringe is recommended for this operation.
- 12.6.3.4** Remove the three-ball Snyder column, add a fresh boiling chip, and attach a two ball micro Snyder column to the concentrator tube. Prewet the column by adding approximately 0.5 mL of solvent through the top. Place the apparatus in the hot water bath.
- 12.6.3.5** Adjust the vertical position and the water temperature as required to complete the concentration in 5 to 10 minutes. At the proper rate of distillation, the balls of the column will actively chatter but the chambers will not flood.
- 12.6.3.6** When the liquid reaches an apparent volume of 0.5 mL, remove the apparatus from the water bath and allow to drain and cool for at least 10 minutes.
- 12.6.3.7** Proceed to 12.6 for preparation for back-extraction or Section 12.7 for micro-concentration and solvent exchange.

12.7 Micro-concentration and solvent exchange

- 12.7.1** Extracts to be subjected to GPC cleanup are exchanged into methylene chloride. Extracts to be cleaned up using silica gel, Florisil, the SPE cartridge, and/or HPLC are exchanged into hexane.
- 12.7.2** Transfer the vial containing the sample extract to a nitrogen evaporation device. Adjust the flow of nitrogen so that the surface of the solvent is just visibly disturbed.

Note: *A large vortex in the solvent may cause analyte loss.*

- 12.7.3** Lower the vial into a 30°C water bath and continue concentrating.
- 12.7.3.1** If the extract or an aliquot of the extract is to be concentrated to dryness for weight determination (Sections 12.4.8 and 13.6.4), blow dry until a constant weight is obtained.
- 12.7.3.2** If the extract is to be concentrated for injection into the GC/HRMS or the solvent is to be exchanged for extract cleanup, proceed as follows:
- 12.7.4** When the volume of the liquid is approximately 100 µL, add 2 to 3 mL of the desired solvent (methylene chloride for GPC and HPLC, or hexane for the other cleanups) and continue concentration to approximately 100 µL. Repeat the addition of solvent and concentrate once more.
- 12.7.5** If the extract is to be cleaned up by GPC, adjust the volume of the extract to 5.0 mL with methylene chloride. If the extract is to be cleaned up by HPLC, concentrate the extract to 1.0 mL. Proceed with GPC or HPLC cleanup (Section 13.2 or 13.5, respectively).
- 12.7.6** If the extract is to be cleaned up by column chromatography or the SPE cartridge, bring the final volume to 1.0 mL with hexane. Proceed with column cleanup (Sections 13.3, 13.4, 13.7, or 13.8).
- 12.7.7** If the extract is to be concentrated for injection into the GC/HRMS (Section 14), quantitatively transfer the extract to a 0.3-mL conical vial for final concentration, rinsing the larger vial with hexane and adding the rinse to the conical vial. Reduce the volume to approximately 100 µL. Add 20 µL of nonane to the vial, and evaporate the solvent to the level of the nonane. Seal the vial and label with the sample number. Store in the dark at room temperature until ready for GC/HRMS analysis. If GC/HRMS analysis will not be performed on the same day, store the vial at less than -10°C.

13.0 Extract cleanup

- 13.1** Cleanup may not be necessary for relatively clean samples (e.g., treated effluents, groundwater, drinking water). If particular circumstances require the use of a cleanup procedure, the laboratory may use any or all of the procedures below or any other appropriate procedure. Before using a cleanup procedure, the laboratory must demonstrate that the requirements of Section 9.2 can be met using the cleanup procedure. The following table suggests cleanups that may be used for the various analyte groups.

Analyte group	Suggested cleanups
All	GPC (13.2); SPE (13.3); Micro-silica (13.4)

Organo-chlorine	GPC, SPE, Micro-silica plus Florisil (13.7) or alumina (13.8)
Specific compounds	GPC, SPE, Micro-silica plus HPLC (13.5)

13.1.1 Gel permeation chromatography (Section 13.2) removes high molecular weight interferences that cause GC column performance to degrade. It should be used for all soil and sediment extracts. It may be used for water extracts that are expected to contain high molecular weight organic compounds (e.g., polymeric materials, humic acids). It should also be used for tissue extracts after initial cleanup on the anthropogenic isolation column (Section 13.6).

13.1.2 Micro-silica (Section 13.4), the SPE cartridge (Section 13.3), Florisil (Section 13.7), and alumina (Section 13.8) may be used to remove non-polar and polar interferences.

13.1.3 HPLC (Section 13.5) is used to provide specificity for certain pesticides.

13.1.4 The anthropogenic isolation column (Section 13.6) is used for removal of lipids from tissue samples.

13.2 Gel permeation chromatography (GPC)

13.2.1 Column packing

13.2.1.1 Place 70 to 75 g of SX-3 Bio-beads (Section 6.7.1.1) in a 400- to 500-mL beaker.

13.2.1.2 Cover the beads with methylene chloride and allow to swell overnight (a minimum of 12 hours).

13.2.1.3 Transfer the swelled beads to the column (Section 6.7.1.1) and pump solvent through the column, from bottom to top, at 4.5 to 5.5 mL/minute prior to connecting the column to the detector.

13.2.1.4 After purging the column with solvent for 1 to 2 hours, adjust the column head pressure to 7 to 10 psig and purge for 4 to 5 hours to remove air. Maintain a head pressure of 7 to 10 psig. Connect the column to the detector (Section 6.7.1.4).

13.2.2 Column calibration

13.2.2.1 Load 5 mL of the GPC calibration solution (Section 7.4) into the sample loop.

13.2.2.2 Inject the GPC calibration solution and record the signal from the detector. The elution pattern will be corn oil, bis(2-ethylhexyl) phthalate (BEHP), methoxychlor, perylene, and sulfur.

- 13.2.2.3** Set the "dump time" to allow >85% removal of BEHP and >85% collection of methoxychlor.
- 13.2.2.4** Set the "collect time" to the time of the sulfur peak maximum.
- 13.2.2.5** Verify calibration with the GPC calibration solution after every 20 extracts. Calibration is verified if the recovery of methoxychlor is greater than 85%. If calibration is not verified, the system must be recalibrated using the GPC calibration solution, and the previous sample batch must be re-extracted and cleaned up using a calibrated GPC system.

13.2.3 Extract cleanup – GPC requires that the column not be overloaded. The column specified in this Method is designed to handle a maximum of 0.5 g of material from an aqueous, soil, or mixed-phase sample in a 5-mL extract, and has been shown to handle 1.5 g of lipid from a tissue sample in a 5-mL extract. If the extract is known or expected to contain more than these amounts, the extract is split into aliquots for GPC, and the aliquots are combined after elution from the column. The residue content of the extract may be obtained gravimetrically by evaporating the solvent from a 50- μ L aliquot.

- 13.2.3.1** Filter the extract or load through the filter holder (Section 6.7.1.3) to remove particles. Load the 5.0-mL extract onto the column.
- 13.2.3.2** Elute the extract using the calibration data determined in Section 13.2.2. Collect the eluate in a clean 400- to 500-mL beaker. Allow the system to rinse for additional 10 minutes before injecting the next sample.
- 13.2.3.3** Rinse the sample loading tube thoroughly with methylene chloride between extracts to prepare for the next sample.
- 13.2.3.4** If an extract is encountered that could overload the GPC column to the extent that carry-over could occur, a 5.0-mL methylene chloride blank must be run through the system to check for carry-over.
- 13.2.3.5** Concentrate the eluate per Sections 12.6 and 12.7 for further cleanup or injection into the GC/MS.

13.3 Solid-phase extraction (SPE) cartridge

13.3.1 Setup

- 13.3.1.1** Attach the Vac-elute manifold (6.7.6.1) to a water aspirator or vacuum pump with the trap and gauge installed between the manifold and vacuum source.

- 13.3.1.2** Place the SPE cartridge(s) in the manifold, turn on the vacuum source, and adjust the vacuum to 5 to 10 psig.

Note: Do not allow the SPE cartridge to go dry during the following steps.

- 13.3.2** Cartridge washing – Pre-elute the cartridge sequentially with two 6-mL volumes of 1:2:1 ethyl acetate:acetonitrile:toluene.
- 13.3.3** Using a pipette or a 1-mL syringe, transfer 1.0 mL of the extract in 1:2:1 ethyl acetate:acetonitrile:toluene (Section 12.2.3.5, 12.3.1.9, 12.4.8 or 12.5.2) onto the SPE cartridge followed by a rinse of 1 mL 1:2:1 ethyl acetate:acetonitrile:toluene.
- 13.3.4** As soon as the sample is loaded, begin to collect the eluate in a round bottom flask or centrifuge tube (if using a manifold). Elute the SPE cartridge with 11 mL of 1:2:1 ethyl acetate:acetonitrile:toluene.
- 13.3.5** Concentrate the eluted extract per Sections 12.6 and 12.7 and proceed to other cleanups or determination by HRGC/HRMS.

13.4 Micro-silica column

- 13.4.1** Place a small glass-wool plug in a clean Pasteur pipette. Rinse the pipette and glass wool twice with small (e.g., 2 - 5 mL) volumes of toluene, followed by two rinsings with small volumes of hexane. Allow the pipette to drain. Dry pack the column bottom to top with 0.75 gram of 10% deactivated silica (Section 7.5.1.1). Tap the column to settle the silica.
- 13.4.2** Rinse the column with hexane until the column is completely wetted (typically 5-10 mL). Allow the hexane to drain to the top of the silica.
- 13.4.3** Adjust the extract volume to 1.0 mL and apply to the column. Allow the extract to drain to the top of the silica. Rinse the extract onto the column with 500 μ L of hexane.
- 13.4.4** Rinse the centrifuge tube that contained the extract with 300- μ L of 10% methanol in dichloromethane and apply to the column. Collect the eluate in a round-bottom flask. Repeat this rinse and collect the eluate in the flask.
- 13.4.5** Elute the column with 5 mL of 10% methanol in dichloromethane. Collect the eluate in the round bottom flask.
- 13.4.6** Add 5 mL of acetone and 1 mL of iso-octane to the round bottom flask and concentrate the eluate per Section 12.6 and 12.7 for further cleanup or injection into the HPLC or GC/MS.

- 13.4.7** For extracts of samples known to contain large quantities of other organic compounds, it may be advisable to increase the capacity of the silica gel column. This may be accomplished by increasing the strength of the acid silica and including basic silica gel. The acid silica gel (Section 7.5.1.2) may be increased in strength to as much as 40% w/w (6.7 g sulfuric acid added to 10 g silica gel). The basic silica gel (Section 7.5.1.3) may be increased in strength to as much as 33% w/w (50 mL 1N NaOH added to 100 g silica gel), or the potassium silicate (Section 7.5.1.4) may be used. Larger columns may also be used if needed.

Note: *The use of stronger acid and basic silica gel (44% w/w) may lead to charring of organic compounds in some extracts. The charred material may retain some of the analytes and lead to lower recoveries of the pesticides. Increasing the strengths of the acid and basic silica gel may also require different volumes of eluants than those specified above to elute the analytes from the column. The performance of the Method after such modifications must be verified by the procedure in Section 9.2.*

13.5 HPLC (Reference 9)

13.5.1 Column calibration

- 13.5.1.1** Prepare a calibration standard containing the pesticides at the concentrations of the stock solution in Table 3, or at a concentration appropriate to the response of the detector.
- 13.5.1.2** Inject the calibration standard into the HPLC and record the signal from the detector. Collect the eluant for reuse.
- 13.5.1.3** Establish the collection time for the pesticides of interest. Following calibration, flush the injection system with solvent to ensure that residual pesticides are removed from the system.
- 13.5.1.4** Verify the calibration with the calibration solution after every 20 extracts. Calibration is verified if the recovery of the pesticides is 75 to 125% compared to the calibration (Section 13.5.1.1). If calibration is not verified, the system must be recalibrated using the calibration solution, and the batch of samples run on the uncalibrated system must be re-extracted and cleaned up using a calibrated system.

- 13.5.2** Extract cleanup – HPLC requires that the column not be overloaded. The column specified in this Method is designed to handle a maximum of 50 μ g of a given pesticide, depending on the particular compound. If the amount of material in the extract will overload the column, split the extract into fractions and combine the fractions after elution from the column.

- 13.5.2.1** Rinse the sides of the vial containing the sample and adjust to the volume required for the sample loop for injection.
- 13.5.2.2** Inject the sample extract into the HPLC.

13.5.2.3 Elute the extract using the calibration data determined in Section 13.5.1. Collect the fraction(s) in clean 20-mL concentrator tubes.

13.5.2.4 If an extract containing greater than 500 µg of total material is encountered, a blank must be run through the system to check for carry-over.

13.5.2.5 Concentrate the eluate per Section 12.7 for injection into the

GC/HRMS.

13.6 Anthropogenic isolation column (Reference 15) – Used for removal of lipids from tissue extracts

13.6.1 Prepare the column as given in Section 7.5.2.

13.6.2 Pre-elute the column with 100 mL of hexane. Drain the hexane layer to the top of the column, but do not expose the sodium sulfate.

13.6.3 Load the sample and rinses (Section 12.4.9.2) onto the column by draining each portion to the top of the bed. Elute the pesticides from the column into the apparatus used for concentration (Section 12.4.7) using 200 mL of hexane.

13.6.4 Remove a small portion (e.g., 50 µL) of the extract for determination of residue content. Estimate the percent of the total that this portion represents. Concentrate the small portion to constant weight per Section 12.7.3.1. Calculate the total amount of residue in the extract. If more than 500 mg of material remains, repeat the cleanup using a fresh anthropogenic isolation column.

13.6.5 If necessary, exchange the extract to a solvent suitable for the additional cleanups to be used (Section 13.2 - 13.8).

13.6.6 Clean up the extract using the procedures in Sections 13.2 - 13.8. GPC (Section 13.2) and Florisil (Section 13.7) are recommended as minimum additional cleanup steps.

13.6.7 Following cleanup, concentrate the extract to 20 ΦL per Section 12.7 and proceed with the analysis in Section 14.

13.7 Florisil

13.7.1 Begin to drain the n-hexane from the column (Section 7.5.4.3). Adjust the flow rate of eluant to 4.5 - 5.0 mL/min.

13.7.2 When the n-hexane is within 1 mm of the sodium sulfate, apply the sample extract (in hexane) to the column. Rinse the sample container twice with 1-mL portions of hexane and apply to the column, allowing the hexane to drain to the top of the sodium sulfate layer.

13.7.3 Elute Fraction 1 with 200 mL of 6% ethyl ether in n-hexane and collect the eluate. Elute Fraction 2 with 200 mL of 15% ethyl ether in hexane and collect the eluate. Elute Fraction 3 with 50% ethyl ether in hexane and collect the eluate. The exact volumes of solvents will need to be determined for each batch of Florisil. If the pesticides are not to be collected in separate fractions, elute all pesticides with 50% ethyl ether in hexane.

13.7.4 Concentrate the eluate(s) per Sections 12.6 - 12.7 for further cleanup or for injection into the HPLC or GC/HRMS.

13.8 Alumina

13.8.1 Begin to drain the hexane from the column (Section 7.5.5.2). Adjust the flow rate of eluant to 4.5 - 5.0 mL/min.

13.8.2 When the n-hexane is within 1 mm of the sodium sulfate, apply the sample extract (in hexane) to the column. Rinse the sample container twice with 1-mL portions of hexane and apply to the column, allowing the hexane to drain to the top of the sodium sulfate layer.

13.8.3 Elute the pesticides with 150 mL of n-hexane. If all pesticides are not eluted, elute the remaining pesticides with 50 mL of 15% methylene chloride in n-hexane.

13.8.4 Concentrate the eluate(s) per Sections 12.6 - 12.7 for further cleanup or for injection into the HPLC or GC/HRMS.

14.0 HRGC/HRMS analysis

14.1 Establish the operating conditions given in Section 10.1.

14.2 Add 2 μL of the labeled injection internal standard spiking solution (Section 7.14) to the 20 μL sample extract immediately prior to injection to minimize the possibility of loss by evaporation, adsorption, or reaction. If an extract is to be reanalyzed and evaporation has occurred, do not add more labeled injection internal standard spiking solution. Rather, bring the extract back to its previous volume (e.g., 19 μL) with pure nonane (18 μL if 2 μL injections are used).

14.3 Inject 1.0 or 2.0 μL of the concentrated extract containing the Labeled injection internal standards using on-column or splitless injection. The volume injected must be identical to the volume used for calibration (Section 10.3).

14.3.1 Start the GC column initial isothermal hold upon injection. Start MS data collection after the solvent peak elutes.

- 14.3.2** Monitor the exact m/z's for each pesticide throughout its retention time window. Where warranted, monitor m/z's associated with pesticides at higher levels of chlorination to assure that fragments are not interfering with the m/z's for pesticides at lower levels of chlorination. Also where warranted, monitor m/z's associated with interferents expected to be present.
- 14.3.3** Stop data collection after permethrin and cypermethrin have eluted. Return the column to the initial temperature for analysis of the next sample extract or standard.

15.0 System and laboratory performance

- 15.1** At the beginning of each 12-hour shift during which analyses are performed, GC/MS system performance and calibration are verified for all the pesticides and labeled compounds. For these tests, analysis of the CS-4 calibration verification (VER) standard (Section 7.10 and Table 4) must be used to verify all performance criteria. Adjustment and/or recalibration (Section 10) must be performed until all performance criteria are met. Only after all performance criteria are met may samples, blanks, IPRs, and OPRs be analyzed.
- 15.2** MS resolution – Static resolving power checks must be performed at the beginning and at the end of each shift per Sections 10.2.1. If analyses are performed on successive shifts, only the beginning of shift static resolving power check is required. If the requirement in Section 10.2.1 cannot be met, the problem must be corrected before analyses can proceed. If any of the samples in the previous shift may be affected by poor resolution, those samples must be re-analyzed.
- 15.3** Calibration verification
- 15.3.1** Inject the VER (CS-4) calibration standard using the procedure in Section 14.
- 15.3.2** The m/z abundance ratios for all pesticides must be within the limits in Table 6; otherwise, the mass spectrometer must be adjusted until the m/z abundance ratios fall within the limits specified when the verification test is repeated. If the adjustment alters the resolution of the mass spectrometer, resolution must be verified (Section 10.2.1) prior to repeat of the verification test.
- 15.3.3** The GC peak representing each native pesticide and labeled compound in the VER standard must be present with a S/N of at least 10; otherwise, the mass spectrometer must be adjusted and the verification test repeated.
- 15.3.4** Compute the concentration of the pesticides that have labeled analogs by isotope dilution and the concentration of the pesticides that do not have labeled analogs by the internal standard technique. These concentrations are computed based on the calibration data in Section 10.

15.3.5 For each compound, compare the concentration with the calibration verification limit in Table 5. If all compounds meet the acceptance criteria, calibration has been verified and analysis of standards and sample extracts may proceed. If, however, any compound fails its respective limit, the measurement system is not performing properly. In this event, prepare a fresh calibration standard or correct the problem and repeat the resolution (Section 15.2) and verification (Section 15.3) tests, or recalibrate (Section 10).

15.4 Retention times and GC resolution

15.4.1 Retention times.

15.4.1.1 Absolute – The absolute retention times of the Labeled compounds in the verification test (Section 15.3) must be within \forall 15 seconds of the respective retention times in the calibration (Section 10.1)

15.4.1.2 Relative – The relative retention times of native pesticides and the labeled compounds in the verification test (Section 15.3) must be within their respective RRT limits in Table 2 or, if an alternate column or column system is employed, within their respective RRT limits for the alternate column or column system (Sections 9.1.2.3 and 6.9.1).

15.4.1.3 If the absolute or relative retention time of any compound is not within the limits specified, the GC is not performing properly. In this event, adjust the GC and repeat the verification test (Section 15.3) or recalibrate (Section 10), or replace the GC column and either verify calibration or recalibrate.

15.4.2 GC resolution and minimum analysis time

15.4.2.1 The resolution and minimum analysis time specifications in Sections 6.9.1.1.2 and 6.9.1.1.1, respectively, must be met for the DB-17 column or, if an alternate column or column system is employed, must be met as specified for the alternate column or column system (Sections 9.1.2.3 and 6.9.1). If these specifications are not met, the GC analysis conditions must be adjusted until the specifications are met, or the column must be replaced and the calibration verification tests repeated (Sections 15.3 - 15.4), or the system must be recalibrated (Section 10).

15.4.2.2 After the resolution and minimum analysis time specifications are met, update the retention times and relative retention times, but not the relative responses and response factors. For the relative responses and response factors, the multi-point calibration data (Sections 10.4 and 10.5) must be used.

- 15.5** Endrin/4,4'-DDT breakdown – Perform the endrin/4,4'-DDT breakdown test (Section 10.6). The breakdown specification (Section 10.6.2.3) must be met before an OPR, sample, or blank may be analyzed.
- 15.6** Ongoing precision and recovery
- 15.6.1** Analyze the extract of the ongoing precision and recovery (OPR) aliquot (Section 11.4.2.5, 11.5.3, 11.6.3, or 11.8.3.2) prior to analysis of samples from the same batch.
- 15.6.2** Compute the percent recovery of the pesticides with labeled analogs by isotope dilution (Section 10.4). Compute the percent recovery of each labeled compound by the internal standard method (Section 10.5).
- 15.6.3** For the pesticides and labeled compounds, compare the recovery to the OPR limits given in Table 5. If all compounds meet the acceptance criteria, system performance is acceptable and analysis of blanks and samples may proceed. If, however, any individual concentration falls outside of the range given, the extraction/concentration processes are not being performed properly for that compound. In this event, correct the problem, re-prepare, extract, and clean up the sample batch and repeat the ongoing precision and recovery test (Section 15.6).
- 15.6.4** If desired, add results that pass the specifications in Section 15.6.3 to initial (Section 9.4) and previous ongoing data for each compound in each matrix. Update QC charts to form a graphic representation of continued laboratory performance. Develop a statement of laboratory accuracy for each pesticide in each matrix type by calculating the average percent recovery (R) and the standard deviation of percent recovery (S_R). Express the accuracy as a recovery interval from $R - 2S_R$ to $R + 2S_R$. For example, if $R = 95\%$ and $S_R = 5\%$, the accuracy is 85 to 105%.
- 15.7** Blank – Analyze the Method blank extracted with each sample batch immediately following analysis of the OPR aliquot to demonstrate freedom from contamination and freedom from carryover from the OPR analysis. If pesticides will be carried from the OPR into the Method blank, analyze one or more aliquots of solvent between the OPR and the Method blank. The results of the analysis of the blank must meet the specifications in Section 9.5.2 before sample analyses may proceed.

16.0 Qualitative determination

A pesticide or labeled compound is identified in a standard, blank, or sample when all of the criteria in Sections 16.1 through 16.4 are met.

- 16.1** The signals for the two exact m/z's in Table 6 must be present and must maximize within the same two scans.
- 16.2** The signal-to-noise ratio (S/N) for the GC peak at each exact m/z must be greater than or equal to 2.5 for each pesticide detected in a sample extract, and greater than or equal to 10 for all pesticides in the calibration and verification standards (Sections 10.3.3 and 15.6.3).
- 16.3** The ratio of the integrated areas of the two exact m/z's specified in Table 6 must be within the limit in Table 6, or within ∇ 15 percent of the ratio in the midpoint (CS-4) calibration or calibration verification (VER), whichever is most recent.
- 16.4** The relative retention time of the peak for a pesticide must be within the RRT QC limits specified in Table 2 or within similar limits developed from calibration data (Section 10.1.2). If an alternate column (Section 9.1.2.3) is employed, the RRT for the pesticide must be within its respective RRT QC limits for the alternate column or column system (Section 6.9.1).

Note: *For native pesticides determined by internal standard quantitation, a pesticide with the same exact m/z's as other pesticides may fall within more than one RT window and be mis-identified unless the RRT windows are made very narrow, as in Table 2. Therefore, consistency of the RT and RRT with other pesticides and the labeled compounds may be required for rigorous pesticide identification. Retention time regression may aid in this identification.*

- 16.5** Because of pesticide RT overlap and the potential for interfering substances, it is possible that all of the identification criteria (Sections 16.1 - 16.4) may not be met. It is also possible that loss of one or more chlorines from a highly chlorinated pesticide or interferent may inflate or produce a false concentration for a less-chlorinated pesticide that elutes at the same retention time (see Section 18). If identification is ambiguous, an experienced spectrometrist (Section 1.5) must determine the presence or absence of the pesticide.
- 16.6** If the criteria for identification in Sections 16.1 - 16.5 are not met, the pesticide has not been identified and the result for that pesticide may not be reported or used for permitting or regulatory compliance purposes. If interferences preclude identification, a new aliquot of sample must be extracted, further cleaned up, and analyzed.

17.0 Quantitative determination

17.1 Isotope dilution quantitation

- 17.1.1** By adding a known amount of the labeled pesticides to every sample prior to extraction, correction for recovery of each pesticide can be made because the native

compound and its labeled analog exhibit similar effects upon extraction, concentration, and gas chromatography. Relative responses (RRs) are used in conjunction with the calibration data in Section 10.4 to determine concentrations in the final extract, so long as labeled compound spiking levels are constant.

- 17.1.2** Compute the concentrations of the pesticides in the extract using the RRs from the calibration data (Section 10.4) and following equation:

$$C_{ex} \text{ (ng/mL)} = \frac{(A1_n + A2_n) C_l}{(A1_l + A2_l) RR}$$

Where:

C_{ex} = The concentration of the pesticide in the extract, and the other terms are as defined in Section 10.4.3

- 17.2** Internal standard quantitation and labeled compound recovery

- 17.2.1** Compute the concentrations in the extract of the native compounds that do not have labeled analogs using the response factors determined from the calibration data (Section 10.5) and the following equation:

$$C_{ex} \text{ (ng/mL)} = \frac{(A1_s + A2_s) C_{is}}{(A1_{is} + A2_{is}) RF}$$

Where:

C_{ex} = The concentration of the labeled compound in the extract, and the other terms are as defined in Section 10.5.1

- 17.2.2** Using the concentration in the extract determined above, compute the percent recovery of the labeled pesticides other labeled cleanup standard using the following equation:

$$\text{Recovery (\%)} = \frac{\text{Concentration found (ng/mL)}}{\text{Concentration spiked (ng/mL)}} \times 100$$

- 17.3** The concentration of a native compound in the solid phase of the sample is computed using the concentration of the compound in the extract and the weight of the solids (Section 11.2.2.3), as follows:

$$\text{Concentration in solid (ng/kg)} = \frac{(C_{ex} \times V_{ex})}{W_s}$$

Where:

C_{ex} = The concentration of the compound in the extract.
 V_{ex} = The extract volume in mL.
 W_s = The sample weight (dry weight) in kg.

- 17.4** The concentration of a native pesticide in the aqueous phase of the sample is computed using the concentration of the compound in the extract and the volume of water extracted (Section 11.4), as follows:

$$\text{Concentration in aqueous phase (pg/L)} = 1000 \times \frac{(C_{ex} \times V_{ex})}{V_s}$$

Where:

- C_{ex} = The concentration of the compound in the extract.
 V_{ex} = The extract volume in mL.
 V_s = The sample volume in liters.

- 17.5** If the SICP area at either quantitation m/z for any pesticide exceeds the calibration range of the system, dilute the sample extract by the factor necessary to bring the concentration within the calibration range, adjust the concentration of the Labeled injection internal standard to 100 pg/ μ L in the extract, and analyze an aliquot of this diluted extract. If the pesticides cannot be measured reliably by isotope dilution, dilute and analyze an aqueous sample or analyze a smaller portion of a soil, tissue, or mixed-phase sample. Adjust the pesticide concentrations, detection limits, and minimum levels to account for the dilution.

17.6 Reporting of results

17.6.1 Reporting units and levels

17.6.1.1 Aqueous samples – Report results in pg/L (parts-per-quadrillion).

17.6.1.2 Samples containing greater than 1% solids (soils, sediments, filter cake, compost) – Report results in ng/kg based on the dry weight of the sample. Report the percent solids so that the result may be converted to aqueous units.

17.6.1.3 Tissues – Report results in ng/kg of wet tissue, not on the basis of the lipid content of the tissue. Report the percent lipid content, so that the data user can calculate the concentration on a lipid basis if desired.

17.6.2 Reporting level

17.6.2.1 Report the result for each pesticide in each sample, blank, or standard (VER, IPR, OPR) at or above the minimum level of quantitation (ML; Table 1) to 3 significant figures. Report the result below the ML in each sample as <ML (where ML is the concentration at the ML) or as required by the regulatory authority or permit.

17.6.2.2 Blanks – Report the result for each pesticide below the ML but above the MDL to 2 significant figures. Report results below the MDL as <MDL (where MDL is the concentration at the MDL) or as required by the regulatory authority or permit. In addition to reporting results for

the samples and blank(s) separately, the concentration of each pesticide in a method blank or field blank associated with the sample may be subtracted from the results for that sample, or must be subtracted if requested or required by a regulatory authority or in a permit.

- 17.6.2.3** Results for a pesticide in a sample that has been diluted are reported at the least dilute level at which the area at the quantitation m/z is within the calibration range (Section 17.5).
- 17.6.2.4** For a pesticide having a labeled analog, report results at the least dilute level at which the area at the quantitation m/z is within the calibration range (Section 17.5) and the labeled compound recovery is within the normal range for the Method (Section 9.3 and Table 5).
- 17.6.2.5** Results from tests performed with an analytical system that is not in control must not be reported or otherwise used for permitting or regulatory compliance purposes, but do not relieve a discharger or permittee of reporting timely results.

18.0 Analysis of complex samples

- 18.1** Some samples may contain high levels (>10 ng/L; >1000 ng/kg) of the compounds of interest, interfering compounds, and/or polymeric materials. Some extracts may not concentrate to 20 μ L (Section 12.7); others may overload the GC column and/or mass spectrometer. A fragment ion from a pesticide at a higher level of chlorination may interfere with determination of a pesticide at a lower level of chlorination.
- 18.2** Analyze a smaller aliquot of the sample (Section 17.5) when the extract will not concentrate to 20 Φ L after all cleanup procedures have been exhausted. If a smaller aliquot of soils or mixed-phase samples is analyzed, attempt to assure that the sample is representative.
- 18.3** Perform integration of peak areas and calculate concentrations manually when interferences preclude computerized calculations.
- 18.4** Recovery of labeled compounds – In most samples, recoveries of the labeled compounds will be similar to those from reagent water or from the alternate matrix (Section 7.6).
 - 18.4.1** If the recovery of any of the labeled compounds is outside of the normal range (Table 5), a diluted sample must be analyzed (Section 17.5).
 - 18.4.2** If the recovery of any of the labeled compounds in the diluted sample is outside of normal range, the calibration verification standard (Section 7.10 and Table 5) must be analyzed and calibration verified (Section 15.3).
 - 18.4.3** If the calibration cannot be verified, a new calibration must be performed and the original sample extract reanalyzed.

18.4.4 If calibration is verified and the diluted sample does not meet the limits for labeled compound recovery, the Method does not apply to the sample being analyzed and the result may not be reported or used for permitting or regulatory compliance purposes. In this case, alternate extraction and cleanup procedures in this Method or an alternate GC column must be employed to resolve the interference. If all cleanup procedures in this Method and an alternate GC column have been employed and labeled compound recovery remains outside of the normal range, extraction and/or cleanup procedures that are beyond this scope of this Method will be required to analyze the sample.

19.0 Pollution prevention

19.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity or toxicity of waste at the point of generation. Many opportunities for pollution prevention exist in laboratory operation. EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address waste generation. When wastes cannot be reduced at the source, the Agency recommends recycling as the next best option.

19.2 The pesticides in this Method are used in extremely small amounts and pose little threat to the environment when managed properly. Standards should be prepared in volumes consistent with laboratory use to minimize the disposal of excess volumes of expired standards.

19.3 For information about pollution prevention that may be applied to laboratories and research institutions, consult *Less is Better: Laboratory Chemical Management for Waste Reduction*, available from the American Chemical Society's Department of Governmental Relations and Science Policy, 1155 16th Street NW, Washington DC 20036, 202/872-4477 (http://membership.acs.org/ccs/pubs/less_is_better.pdf).

20.0 Waste management

20.1 The laboratory is responsible for complying with all Federal, State, and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions, and to protect the air, water, and land by minimizing and controlling all releases from fume hoods and bench operations. Compliance is also required with any sewage discharge permits and regulations. An overview of requirements can be found in *Environmental Management Guide for Small Laboratories* (EPA 233-B-98-001).

20.2 Samples containing HCl or H₂SO₄ to pH <2, or KOH or NaOH to pH >12 must be handled as hazardous waste, or must be neutralized before being poured down a drain.

20.3 The pesticides decompose above 800°C. Low-level waste such as absorbent paper, tissues, animal remains, and plastic gloves may be burned in an appropriate incinerator. Gross

quantities (milligrams) should be packaged securely and disposed of through commercial or governmental channels that are capable of handling extremely toxic wastes.

- 20.4** For further information on waste management, consult *The Waste Management Manual for Laboratory Personnel* and *Less is Better-Laboratory Chemical Management for Waste Reduction*, available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th Street N.W., Washington, D.C. 20036.

21.0 Method performance

Method 1699 was validated and preliminary data were collected in a single laboratory (Reference 2). Single laboratory performance data are included in Table 8.

1. Retention time of pesticide or labeled compound.
2. Relative retention time (RRT) between the target and reference compounds.
3. RRT limits based on estimated RRT variability.
4. Labeled compounds that form both the retention time and quantitation reference.
5. Method detection limits (MDLs) and minimum levels of quantitation (MLs) with no interferences present.

Table 3. Concentrations of native and labeled pesticides in stock solutions, spiking solutions, and final extracts

¹⁹ F	18.9984
¹⁴ N	14.0031
¹⁶ O	15.9949

Table 7. Suggested sample quantities to be extracted for various matrices¹

Sample matrix ²	Example	Percent solids	Phase	Quantity extracted
Single-phase				
Aqueous	Drinking water	<1	— ³	1000 mL
	Groundwater			
	Treated wastewater			
Solid	Dry soil	>20	Solid	10 g
	Compost			
	Ash			
Organic	Waste solvent	<1	Organic	10 g
	Waste oil			
	Organic polymer			
Tissue	Fish	—	Organic	10 g
	Human adipose			
Multi-phase				
Liquid/Solid				
Aqueous/Solid	Wet soil	1-30	Solid	10 g
	Untreated effluent			
	Digested municipal sludge			
	Filter cake			
	Paper pulp			
Organic/solid	Industrial sludge	1-100	Both	10 g
	Oily waste			
Liquid/Liquid				
Aqueous/organic	In-process effluent	<1	Organic	10 g
	Untreated effluent			
	Drum waste			
Aqueous/organic/solid	Untreated effluent	>1	Organic & solid	10 g
	Drum waste			

1. The quantity of sample to be extracted is adjusted to provide 10 g of solids (dry weight). One liter of aqueous samples containing one percent solids will contain 10 grams of solids. For aqueous samples containing greater than one percent solids, a lesser volume is used so that 10 grams of solids (dry weight) will be extracted.
2. The sample matrix may be amorphous for some samples. In general, when the pesticides are in contact with a multi-phase system in which one of the phases is water, they will be preferentially dispersed in or adsorbed on the alternate phase because of their low water solubility.

3. Aqueous samples are filtered after spiking with the labeled compounds. The filtrate and the materials trapped on the filter are extracted separately, and the extracts are combined for cleanup and analysis.

Table 8. Performance data from single laboratory validation.

	Solid-Based			Reagent Water-Based			Biosolids-Based on 8 (native)		
	on 5 samples			on 4 samples			or 6 (label) samples

24.0 Glossary

These definitions and purposes are specific to this Method but have been conformed to common usage to the extent possible.

24.1 Units of weight and measure

24.1.1 Symbols

EC	degrees Celsius
ΦL	microliter
Φm	micrometer
<	less than
>	greater than
%	percent

24.1.2 Alphabetical abbreviations

cm	centimeter
g	gram
h	hour
ID	inside diameter
in.	inch
L	liter
M	Molecular ion
m	mass or meter
mg	milligram
min	minute
mL	milliliter
mm	millimeter
m/z	mass-to-charge ratio
N	normal; gram molecular weight of solute divided by hydrogen equivalent of solute, per liter of solution
OD	outside diameter
pg	picogram
ppb	part-per-billion
ppm	part-per-million
ppq	part-per-quadrillion
ppt	part-per-trillion
psig	pounds-per-square inch gauge
v/v	volume per unit volume
w/v	weight per unit volume

25.0 Definitions and acronyms (in alphabetical order)

Analyte – A pesticide tested for by this Method. The analytes are listed in Table 1.

Calibration standard (CAL) – A solution prepared from a secondary standard and/or stock solution and used to calibrate the response of the HRGC/HRMS instrument.

Calibration verification standard (VER) – The mid-point calibration standard (CS-4) that is used to verify calibration. See Table 4.

CS-1, CS-2, CS-3, CS-4, CS-5, CS-6 – See Calibration standards and Table 4.

Field blank – An aliquot of reagent water or other reference matrix that is placed in a sample container in the field, and treated as a sample in all respects, including exposure to sampling site conditions, storage, preservation, and all analytical procedures. The purpose of the field blank is to determine if the field or sample transporting procedures and environments have contaminated the sample.

GC – Gas chromatograph or gas chromatography

GPC – Gel permeation chromatograph or gel permeation chromatography

HPLC – High performance liquid chromatograph or high performance liquid chromatography

HRGC – High resolution GC

HRMS – High resolution MS

Labeled injection internal standard – Labeled PCB52 is spiked into the concentrated extract immediately prior to injection of an aliquot of the extract into the HRGC/HRMS.

Internal standard – a labeled compound used as a reference for quantitation of other labeled compounds and for quantitation of native pesticides other than the pesticide of which it is a labeled analog. See Internal standard quantitation.

Internal standard quantitation – A means of determining the concentration of (1) a naturally occurring (native) compound by reference to a compound other than its labeled analog and (2) a labeled compound by reference to another labeled compound.

IPR – Initial precision and recovery; four aliquots of a reference matrix spiked with the analytes of interest and labeled compounds and analyzed to establish the ability of the laboratory to generate acceptable precision and recovery. An IPR is performed prior to the first time this Method is used and any time the Method or instrumentation is modified.

Isotope dilution quantitation – A means of determining a naturally occurring (native) compound by reference to the same compound in which one or more atoms has been isotopically enriched. In this Method, labeled are enriched with carbon-13 to produce ¹³C-labeled analogs. The ¹³C-labeled pesticides are spiked into each sample to allow identification and correction of the concentration of the native compounds in the analytical process.

K-D – Kuderna-Danish concentrator; a device used to concentrate the analytes in a solvent

Laboratory blank – See Method blank

Laboratory control sample (LCS) – See Ongoing precision and recovery standard (OPR)

Laboratory reagent blank – See Method blank

May – This action, activity, or procedural step is neither required nor prohibited.

May not – This action, activity, or procedural step is prohibited.

Method blank – An aliquot of reagent water that is treated exactly as a sample including exposure to all glassware, equipment, solvents, reagents, internal standards, and surrogates that are used with samples. The Method blank is used to determine if analytes or interferences are present in the laboratory environment, the reagents, or the apparatus.

Method detection limit (MDL) – The lowest concentration at which a pesticide can be detected under routine operating conditions (see 40 CFR 136, appendix B). MDLs are listed in Table 1.

Minimum level (ML) – The greater of a multiple of the MDL or the lowest calibration point (see 68 FR 11790, March 12, 2003.)

MS – Mass spectrometer or mass spectrometry

Must – This action, activity, or procedural step is required.

OPR – Ongoing precision and recovery standard (OPR); a method blank spiked with known quantities of analytes. The OPR is analyzed exactly like a sample. Its purpose is to assure that the results produced by the laboratory remain within the limits specified in this Method for precision and recovery.

Perfluorokerosene (PFK) – A mixture of compounds used to calibrate the exact m/z scale in the HRMS.

Preparation blank – See Method blank

Quality control check sample (QCS) – A sample containing all or a subset of the analytes at known concentrations. The QCS is obtained from a source external to the laboratory or is prepared from a source of standards different from the source of calibration standards. It is used to check laboratory performance with test materials prepared external to the normal preparation process.

Reagent water – water demonstrated to be free from the analytes of interest and potentially interfering substances at the method detection limit for the analyte.

Relative standard deviation (RSD) – The standard deviation times 100 divided by the mean. Also termed "coefficient of variation."

RF – Response factor. See Section 10.5

RR – Relative response. See Section 10.4

RSD – See relative standard deviation

SDS – Soxhlet/Dean-Stark extractor; an extraction device applied to the extraction of solid and semi-solid materials (Reference 3 and Figure 5).

Signal-to-noise ratio (S/N) – The height of the signal as measured from the mean (average) of the noise to the peak maximum divided by the width of the noise.

Should – Although this action, activity, or procedural step is suggested and not required, you may be asked why you changed or omitted this action, activity, or procedural step.

SICP – Selected ion current profile; the line described by the signal at an exact m/z.

SPE – Solid-phase extraction; an extraction technique in which an analyte is extracted from an aqueous sample by passage over or through a material capable of reversibly adsorbing the analyte. Also termed liquid-solid extraction.

Stock solution – A solution containing an analyte that is prepared using a reference material traceable to EPA, the National Institute of Science and Technology (NIST), or a source that will attest to the purity and authenticity of the reference material.

Unique GC resolution or uniquely resolved – Two adjacent chromatographic peaks in which the height of the valley is less than 10 percent of the height of the shorter peak (see Section 6.9.1.1.2).

VER – See Calibration verification.

No. L-12

Volatile Organics

SW-846 Method 8260B

METHOD 8260B
VOLATILE ORGANIC COMPOUNDS BY GAS CHROMATOGRAPHY/
 MASS SPECTROMETRY (GC/MS)

1.0 SCOPE AND APPLICATION

1.1 Method 8260 is used to determine volatile organic compounds in a variety of solid waste matrices. This method is applicable to nearly all types of samples, regardless of water content, including various air sampling trapping media, ground and surface water, aqueous sludges, caustic liquors, acid liquors, waste solvents, oily wastes, mousses, tars, fibrous wastes, polymeric emulsions, filter cakes, spent carbons, spent catalysts, soils, and sediments. The following compounds can be determined by this method:

Compound	CAS No. ^b	Appropriate Preparation Technique ^a					Direct Inject.
		5030/ 5035	5031	5032	5021	5041

^b Chemical Abstract Service Registry Number

- c = Adequate response by this technique
- ht = Method analyte only when purged at 80°C
- nd = Not determined
- l = Inappropriate technique for this analyte
- pc = Poor chromatographic behavior
- pp = Poor purging efficiency resulting in high Estimated Quantitation Limits
- surr = Surrogate
- IS = Internal Standard

1.2 There are various techniques by which these compounds may be introduced into the GC/MS system. The more common techniques are listed in the table above. Purge-and-trap, by Methods 5030 (aqueous samples) and 5035 (solid and waste oil samples), is the most commonly used technique for volatile organic analytes. However, other techniques are also appropriate and necessary for some analytes. These include direct injection following dilution with hexadecane (Method 3585) for waste oil samples; automated static headspace by Method 5021 for solid samples; direct injection of an aqueous sample (concentration permitting) or injection of a sample concentrated by azeotropic distillation (Method 5031); and closed system vacuum distillation (Method 5032) for aqueous, solid, oil and tissue samples. For air samples, Method 5041 provides methodology for desorbing volatile organics from trapping media (Methods 0010, 0030, and 0031). In addition, direct analysis utilizing a sample loop is used for sub-sampling from Tedlar® bags (Method 0040). Method 5000 provides more general information on the selection of the appropriate introduction method.

1.3 Method 8260 can be used to quantitate most volatile organic compounds that have boiling points below 200°C. Volatile, water soluble compounds can be included in this analytical technique by the use of azeotropic distillation or closed-system vacuum distillation. Such compounds include low molecular weight halogenated hydrocarbons, aromatics, ketones, nitriles, acetates, acrylates, ethers, and sulfides. See Tables 1 and 2 for analytes and retention times that have been evaluated on a purge-and-trap GC/MS system. Also, the method detection limits for 25-mL sample volumes are presented. The following compounds are also amenable to analysis by Method 8260:

Bromobenzene	1,3-Dichloropropane
n-Butylbenzene	2,2-Dichloropropane
sec-Butylbenzene	1,1-Dichloropropene
tert-Butylbenzene	p-Isopropyltoluene
Chloroacetonitrile	Methyl acrylate
1-Chlorobutane	Methyl-t-butyl ether
1-Chlorohexane	Pentafluorobenzene
2-Chlorotoluene	n-Propylbenzene
4-Chlorotoluene	1,2,3-Trichlorobenzene
Dibromofluoromethane	1,2,4-Trimethylbenzene
cis-1,2-Dichloroethene	1,3,5-Trimethylbenzene

1.4 The estimated quantitation limit (EQL) of Method 8260 for an individual compound is somewhat instrument dependent and also dependent on the choice of sample preparation/introduction method. Using standard quadrupole instrumentation and the purge-and-trap technique, limits should be approximately 5 µg/kg (wet weight) for soil/sediment samples, 0.5 mg/kg (wet weight) for wastes, and 5 µg/L for ground water (see Table 3). Somewhat lower limits may be achieved using an ion trap mass spectrometer or other instrumentation of improved design. No matter which instrument is used, EQLs will be proportionately higher for sample extracts and samples that require dilution or when a reduced sample size is used to avoid saturation of the detector.

1.5 This method is restricted to use by, or under the supervision of, analysts experienced in the use of gas chromatograph/mass spectrometers, and skilled in the interpretation of mass spectra and their use as a quantitative tool.

2.0 SUMMARY OF METHOD

2.1 The volatile compounds are introduced into the gas chromatograph by the purge-and-trap method or by other methods (see Sec. 1.2). The analytes are introduced directly to a wide-bore capillary column or cryofocused on a capillary pre-column before being flash evaporated to a narrow-bore capillary for analysis. The column is temperature-programmed to separate the analytes, which are then detected with a mass spectrometer (MS) interfaced to the gas chromatograph (GC).

2.2 Analytes eluted from the capillary column are introduced into the mass spectrometer via a jet separator or a direct connection. (Wide-bore capillary columns normally require a jet separator, whereas narrow-bore capillary columns may be directly interfaced to the ion source). Identification of target analytes is accomplished by comparing their mass spectra with the electron impact (or electron impact-like) spectra of authentic standards. Quantitation is accomplished by comparing the response of a major (quantitation) ion relative to an internal standard using a five-point calibration curve.

2.3 The method includes specific calibration and quality control steps that supersede the general requirements provided in Method 8000.

3.0 INTERFERENCES

3.1 Major contaminant sources are volatile materials in the laboratory and impurities in the inert purging gas and in the sorbent trap. The use of non-polytetrafluoroethylene (PTFE) thread sealants, plastic tubing, or flow controllers with rubber components should be avoided, since such materials out-gas organic compounds which will be concentrated in the trap during the purge operation. Analyses of calibration and reagent blanks provide information about the presence of contaminants. When potential interfering peaks are noted in blanks, the analyst should change the purge gas source and regenerate the molecular sieve purge gas filter. Subtracting blank values from sample results is not permitted. If reporting values without correcting for the blank results in what the laboratory feels is a false positive result for a sample, the laboratory should fully explain this in text accompanying the uncorrected data.

3.2 Contamination may occur when a sample containing low concentrations of volatile organic compounds is analyzed immediately after a sample containing high concentrations of volatile organic compounds. A technique to prevent this problem is to rinse the purging apparatus and sample syringes with two portions of organic-free reagent water between samples. After the analysis of a sample containing high concentrations of volatile organic compounds, one or more blanks should be analyzed to check for cross-contamination. Alternatively, if the sample immediately following the high concentration sample does not contain the volatile organic compounds present in the high level sample, freedom from contamination has been established.

3.3 For samples containing large amounts of water-soluble materials, suspended solids, high boiling compounds, or high concentrations of compounds being determined, it may be necessary to wash the purging device with a soap solution, rinse it with organic-free reagent water, and then dry the purging device in an oven at 105°C. In extreme situations, the entire purge-and-trap device may require dismantling and cleaning. Screening of the samples prior to purge-and-trap GC/MS analysis is highly recommended to prevent contamination of the system. This is especially true for soil and waste samples. Screening may be accomplished with an automated headspace technique (Method 5021) or by Method 3820 (Hexadecane Extraction and Screening of Purgeable Organics).

3.4 Many analytes exhibit low purging efficiencies from a 25-mL sample. This often results in significant amounts of these analytes remaining in the sample purge vessel after analysis. After removal of the sample aliquot that was purged, and rinsing the purge vessel three times with organic-free water, the empty vessel should be subjected to a heated purge cycle prior to the analysis of another sample in the same purge vessel. This will reduce sample-to-sample carryover.

3.5 Special precautions must be taken to analyze for methylene chloride. The analytical and sample storage area should be isolated from all atmospheric sources of methylene chloride. Otherwise, random background levels will result. Since methylene chloride will permeate through PTFE tubing, all gas chromatography carrier gas lines and purge gas plumbing should be constructed from stainless steel or copper tubing. Laboratory clothing worn by the analyst should be clean, since clothing previously exposed to methylene chloride fumes during liquid/liquid extraction procedures can contribute to sample contamination.

3.6 Samples can be contaminated by diffusion of volatile organics (particularly methylene chloride and fluorocarbons) through the septum seal of the sample container into the sample during shipment and storage. A trip blank prepared from organic-free reagent water and carried through the sampling, handling, and storage protocols can serve as a check on such contamination.

3.7 Use of sensitive mass spectrometers to achieve lower detection level will increase the potential to detect laboratory contaminants as interferences.

3.8 Direct injection - Some contamination may be eliminated by baking out the column between analyses. Changing the injector liner will reduce the potential for cross-contamination. A portion of the analytical column may need to be removed in the case of extreme contamination. The use of direct injection will result in the need for more frequent instrument maintenance.

3.9 If hexadecane is added to waste samples or petroleum samples that are analyzed, some chromatographic peaks will elute after the target analytes. The oven temperature program must include a post-analysis bake out period to ensure that semivolatile hydrocarbons are volatilized.

4.0 APPARATUS AND MATERIALS

4.1 Purge-and-trap device for aqueous samples - Described in Method 5030.

4.2 Purge-and-trap device for solid samples - Described in Method 5035.

4.3 Automated static headspace device for solid samples - Described in Method 5021.

4.4 Azeotropic distillation apparatus for aqueous and solid samples - Described in Method 5031.

4.5 Vacuum distillation apparatus for aqueous, solid and tissue samples - Described in Method 5032.

4.6 Desorption device for air trapping media for air samples - Described in Method 5041.

4.7 Air sampling loop for sampling from Tedlar® bags for air samples - Described in Method 0040.

4.8 Injection port liners (HP Catalog #18740-80200, or equivalent) - modified for direct injection analysis by placing a 1-cm plug of glass wool approximately 50-60 mm down the length of the injection port towards the oven (see illustration below). A 0.53-mm ID column is mounted 1 cm into the liner from the oven side of the injection port, according to manufacturer's specifications.

4.9 Gas chromatography/mass spectrometer/data system

4.9.1 Gas chromatograph - An analytical system complete with a temperature-programmable gas chromatograph suitable for splitless injection with appropriate interface for sample introduction device. The system includes all required accessories, including syringes, analytical columns, and gases.

4.9.1.1 The GC should be equipped with variable constant differential flow controllers so that the column flow rate will remain constant throughout desorption and temperature program operation.

4.9.1.2 For some column configurations, the column oven must be cooled to less than 30°C, therefore, a subambient oven controller may be necessary.

4.9.1.3 The capillary column is either directly coupled to the source or interfaced through a jet separator, depending on the size of the capillary and the requirements of the GC/MS system.

4.9.1.4 Capillary pre-column interface - This device is the interface between the sample introduction device and the capillary gas chromatograph, and is necessary when using cryogenic cooling. The interface condenses the desorbed sample components and focuses them into a narrow band on an uncoated fused-silica capillary pre-column. When the interface is flash heated, the sample is transferred to the analytical capillary column.

4.9.1.5 During the cryofocussing step, the temperature of the fused-silica in the interface is maintained at -150°C under a stream of liquid nitrogen. After the desorption period, the interface must be capable of rapid heating to 250°C in 15 seconds or less to complete the transfer of analytes.

4.9.2 Gas chromatographic columns

4.9.2.1 Column 1 - 60 m x 0.75 mm ID capillary column coated with VOCOL (Supelco), 1.5-µm film thickness, or equivalent.

4.9.2.2 Column 2 - 30 - 75 m x 0.53 mm ID capillary column coated with DB-624 (J&W Scientific), Rt_x-502.2 (RESTEK), or VOCOL (Supelco), 3-µm film thickness, or equivalent.

4.9.2.3 Column 3 - 30 m x 0.25 - 0.32 mm ID capillary column coated with 95% dimethyl - 5% diphenyl polysiloxane (DB-5, Rt_x-5, SPB-5, or equivalent), 1-µm film thickness.

4.9.2.4 Column 4 - 60 m x 0.32 mm ID capillary column coated with DB-624 (J&W Scientific), 1.8-µm film thickness, or equivalent.

4.9.3 Mass spectrometer - Capable of scanning from 35 to 300 amu every 2 sec or less, using 70 volts (nominal) electron energy in the electron impact ionization mode. The mass spectrometer must be capable of producing a mass spectrum for 4-Bromofluorobenzene (BFB) which meets all of the criteria in Table 4 when 5-50 ng of the GC/MS tuning standard (BFB) are injected through the GC. To ensure sufficient precision of mass spectral data, the desirable MS scan rate allows acquisition of at least five spectra while a sample component elutes from the GC.

An ion trap mass spectrometer may be used if it is capable of axial modulation to reduce ion-molecule reactions and can produce electron impact-like spectra that match those in the EPA/NIST Library. Because ion-molecule reactions with water and methanol in an ion trap mass spectrometer may produce interferences that coelute with chloromethane and chloroethane, the base peak for both of these analytes will be at m/z 49. This ion should be used as the quantitation ion in this case. The mass spectrometer must be capable of producing a mass spectrum for BFB which meets all of the criteria in Table 3 when 5 or 50 ng are introduced.

4.9.4 GC/MS interface - Two alternatives may be used to interface the GC to the mass spectrometer.

4.9.4.1 Direct coupling, by inserting the column into the mass spectrometer, is generally used for 0.25 - 0.32 mm ID columns.

4.9.4.2 A jet separator, including an all-glass transfer line and glass enrichment device or split interface, is used with a 0.53 mm column.

4.9.4.3 Any enrichment device or transfer line may be used, if all of the performance specifications described in Sec. 8.0 (including acceptable calibration at 50 ng or less) can be achieved. GC/MS interfaces constructed entirely of glass or of glass-lined materials are recommended. Glass may be deactivated by silanizing with dichlorodimethylsilane.

4.9.5 Data system - A computer system that allows the continuous acquisition and storage on machine-readable media of all mass spectra obtained throughout the duration of the chromatographic program must be interfaced to the mass spectrometer. The computer must have software that allows searching any GC/MS data file for ions of a specified mass and plotting such ion abundances versus time or scan number. This type of plot is defined as an Extracted Ion Current Profile (EICP). Software must also be available that allows integrating the abundances in any EICP between specified time or scan-number limits. The most recent version of the EPA/NIST Mass Spectral Library should also be available.

4.10 Microsyringes - 10-, 25-, 100-, 250-, 500-, and 1,000- μ L.

4.11 Syringe valve - Two-way, with Luer ends (three each), if applicable to the purging device.

4.12 Syringes - 5-, 10-, or 25-mL, gas-tight with shutoff valve.

4.13 Balance - Analytical, capable of weighing 0.0001 g, and top-loading, capable of weighing 0.1 g.

4.14 Glass scintillation vials - 20-mL, with PTFE-lined screw-caps or glass culture tubes with PTFE-lined screw-caps.

- 4.15 Vials - 2-mL, for GC autosampler.
- 4.16 Disposable pipets - Pasteur.
- 4.17 Volumetric flasks, Class A - 10-mL and 100-mL, with ground-glass stoppers.
- 4.18 Spatula - Stainless steel.

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all inorganic reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Organic-free reagent water - All references to water in this method refer to organic-free reagent water, as defined in Chapter One.

5.3 Methanol, CH₃OH - Pesticide quality or equivalent, demonstrated to be free of analytes. Store apart from other solvents.

5.4 Reagent Hexadecane - Reagent hexadecane is defined as hexadecane in which interference is not observed at the method detection limit of compounds of interest. Hexadecane quality is demonstrated through the analysis of a solvent blank injected directly into the GC/MS. The results of such a blank analysis must demonstrate that all interfering volatiles have been removed from the hexadecane.

5.5 Polyethylene glycol, H(OCH₂CH₂)_nOH - Free of interferences at the detection limit of the target analytes.

5.6 Hydrochloric acid (1:1 v/v), HCl - Carefully add a measured volume of concentrated HCl to an equal volume of organic-free reagent water.

5.7 Stock solutions - Stock solutions may be prepared from pure standard materials or purchased as certified solutions. Prepare stock standard solutions in methanol, using assayed liquids or gases, as appropriate.

5.7.1 Place about 9.8 mL of methanol in a 10-mL tared ground-glass-stoppered volumetric flask. Allow the flask to stand, unstoppered, for about 10 minutes or until all alcohol-wetted surfaces have dried. Weigh the flask to the nearest 0.0001 g.

5.7.2 Add the assayed reference material, as described below.

5.7.2.1 Liquids - Using a 100- μ L syringe, immediately add two or more drops of assayed reference material to the flask; then reweigh. The liquid must fall directly into the alcohol without contacting the neck of the flask.

5.7.2.2 Gases - To prepare standards for any compounds that boil below 30°C (e.g., bromomethane, chloroethane, chloromethane, or vinyl chloride), fill a 5-mL valved gas-tight syringe with the reference standard to the 5.0 mL mark. Lower the needle to

5 mm above the methanol meniscus. Slowly introduce the reference standard above the surface of the liquid. The heavy gas will rapidly dissolve in the methanol. Standards may also be prepared by using a lecture bottle equipped with a septum. Attach PTFE tubing to the side arm relief valve and direct a gentle stream of gas into the methanol meniscus.

5.7.3 Reweigh, dilute to volume, stopper, and then mix by inverting the flask several times. Calculate the concentration in milligrams per liter (mg/L) from the net gain in weight. When compound purity is assayed to be 96% or greater, the weight may be used without correction to calculate the concentration of the stock standard. Commercially-prepared stock standards may be used at any concentration if they are certified by the manufacturer or by an independent source.

5.7.4 Transfer the stock standard solution into a bottle with a PTFE-lined screw-cap. Store, with minimal headspace and protected from light, at -10°C or less or as recommended by the standard manufacturer. Standards should be returned to the freezer as soon as the analyst has completed mixing or diluting the standards to prevent the evaporation of volatile target compounds.

5.7.5 Frequency of Standard Preparation

5.7.5.1 Standards for the permanent gases should be monitored frequently by comparison to the initial calibration curve. Fresh standards should be prepared if this check exceeds a 20% drift. Standards for gases usually need to be replaced after one week or as recommended by the standard manufacturer, unless the acceptability of the standard can be documented. Dichlorodifluoromethane and dichloromethane will usually be the first compounds to evaporate from the standard and should, therefore, be monitored very closely when standards are held beyond one week.

5.7.5.2 Standards for the non-gases should be monitored frequently by comparison to the initial calibration. Fresh standards should be prepared if this check exceeds a 20% drift. Standards for non-gases usually need to be replaced after six months or as recommended by the standard manufacturer, unless the acceptability of the standard can be documented. Standards of reactive compounds such as 2-chloroethyl vinyl ether and styrene may need to be prepared more frequently.

5.7.6 Preparation of Calibration Standards From a Gas Mixture

An optional calibration procedure involves using a certified gaseous mixture daily, utilizing a commercially-available gaseous analyte mixture of bromomethane, chloromethane, chloroethane, vinyl chloride, dichloro-difluoromethane and trichlorofluoromethane in nitrogen. Mixtures of documented quality are stable for as long as six months without refrigeration. (VOA-CYL III, RESTEK Corporation, Cat. #20194 or equivalent).

5.7.6.1 Before removing the cylinder shipping cap, be sure the valve is completely closed (turn clockwise). The contents are under pressure and should be used in a well-ventilated area.

5.7.6.2 Wrap the pipe thread end of the Luer fitting with PTFE tape. Remove the shipping cap from the cylinder and replace it with the Luer fitting.

5.7.6.3 Transfer half the working standard containing other analytes, internal standards, and surrogates to the purge apparatus.

5.7.6.4 Purge the Luer fitting and stem on the gas cylinder prior to sample removal using the following sequence:

- a) Connect either the 100- μ L or 500- μ L Luer syringe to the inlet fitting of the cylinder.
- b) Make sure the on/off valve on the syringe is in the open position.
- c) Slowly open the valve on the cylinder and withdraw a full syringe volume.
- d) Be sure to close the valve on the cylinder before you withdraw the syringe from the Luer fitting.
- e) Expel the gas from the syringe into a well-ventilated area.
- f) Repeat steps a through e one more time to fully purge the fitting.

5.7.6.5 Once the fitting and stem have been purged, quickly withdraw the volume of gas you require using steps 5.6.6.1.4(a) through (d). Be sure to close the valve on the cylinder and syringe before you withdraw the syringe from the Luer fitting.

5.7.6.6 Open the syringe on/off valve for 5 seconds to reduce the syringe pressure to atmospheric pressure. The pressure in the cylinder is ~30 psi.

5.7.6.7 The gas mixture should be quickly transferred into the reagent water through the female Luer fitting located above the purging vessel.

NOTE: Make sure the arrow on the 4-way valve is pointing toward the female Luer fitting when transferring the sample from the syringe. Be sure to switch the 4-way valve back to the closed position before removing the syringe from the Luer fitting.

5.7.6.8 Transfer the remaining half of the working standard into the purging vessel. This procedure insures that the total volume of gas mix is flushed into the purging vessel, with none remaining in the valve or lines.

5.7.6.9 The concentration of each compound in the cylinder is typically 0.0025 μ g/ μ L.

5.7.6.10 The following are the recommended gas volumes spiked into 5 mL of water to produce a typical 5-point calibration:

<u>Gas Volume</u>	<u>Calibration Concentration</u>
40 μ L	20 μ g/L
100 μ L	50 μ g/L
200 μ L	100 μ g/L
300 μ L	150 μ g/L
400 μ L	200 μ g/L

5.7.6.11 The following are the recommended gas volumes spiked into 25 mL of water to produce a typical 5-point calibration:

<u>Gas Volume</u>	<u>Calibration Concentration</u>
10 µL	1 µg/L
20 µL	2 µg/L
50 µL	5 µg/L
100 µL	10 µg/L
250 µL	25 µg/L

5.8 Secondary dilution standards - Using stock standard solutions, prepare secondary dilution standards in methanol containing the compounds of interest, either singly or mixed together. Secondary dilution standards must be stored with minimal headspace and should be checked frequently for signs of degradation or evaporation, especially just prior to preparing calibration standards from them. Store in a vial with no headspace. Replace after one week. Secondary standards for gases should be replaced after one week unless the acceptability of the standard can be documented. When using premixed certified solutions, store according to the manufacturer's documented holding time and storage temperature recommendations. The analyst should also handle and store standards as stated in Sec. 5.7.4 and return them to the freezer as soon as standard mixing or diluting is completed to prevent the evaporation of volatile target compounds.

5.9 Surrogate standards - The recommended surrogates are toluene-d₈, 4-bromofluorobenzene, 1,2-dichloroethane-d₄, and dibromofluoromethane. Other compounds may be used as surrogates, depending upon the analysis requirements. A stock surrogate solution in methanol should be prepared as described above, and a surrogate standard spiking solution should be prepared from the stock at a concentration of 50-250 µg/10 mL, in methanol. Each sample undergoing GC/MS analysis must be spiked with 10 µL of the surrogate spiking solution prior to analysis. If a more sensitive mass spectrometer is employed to achieve lower detection levels, then more dilute surrogate solutions may be required.

5.10 Internal standards - The recommended internal standards are fluorobenzene, chlorobenzene-d₅, and 1,4-dichlorobenzene-d₄. Other compounds may be used as internal standards as long as they have retention times similar to the compounds being detected by GC/MS. Prepare internal standard stock and secondary dilution standards in methanol using the procedures described in Secs. 5.7 and 5.8. It is recommended that the secondary dilution standard be prepared at a concentration of 25 mg/L of each internal standard compound. Addition of 10 µL of this standard to 5.0 mL of sample or calibration standard would be the equivalent of 50 µg/L. If a more sensitive mass spectrometer is employed to achieve lower detection levels, then more dilute internal standard solutions may be required. Area counts of the internal standard peaks should be between 50-200% of the areas of the target analytes in the mid-point calibration analysis.

5.11 4-Bromofluorobenzene (BFB) standard - A standard solution containing 25 ng/µL of BFB in methanol should be prepared. If a more sensitive mass spectrometer is employed to achieve lower detection levels, then a more dilute BFB standard solution may be required.

5.12 Calibration standards - There are two types of calibration standards used for this method: initial calibration standards and calibration verification standards. When using premixed certified solutions, store according to the manufacturer's documented holding time and storage temperature recommendations.

5.12.1 Initial calibration standards should be prepared at a minimum of five different concentrations from the secondary dilution of stock standards (see Secs. 5.7 and 5.8) or from a premixed certified solution. Prepare these solutions in organic-free reagent water. At least one of the calibration standards should correspond to a sample concentration at or below that necessary to meet the data quality objectives of the project. The remaining standards should correspond to the range of concentrations found in typical samples but should not exceed the working range of the GC/MS system. Initial calibration standards should be mixed from fresh stock standards and dilution standards when generating an initial calibration curve.

5.12.2 Calibration verification standards should be prepared at a concentration near the mid-point of the initial calibration range from the secondary dilution of stock standards (see Secs. 5.7 and 5.8) or from a premixed certified solution. Prepare these solutions in organic-free reagent water. See Sec. 7.4 for guidance on calibration verification.

5.12.3 It is the intent of EPA that all target analytes for a particular analysis be included in the initial calibration and calibration verification standard(s). These target analytes may not include the entire list of analytes (Sec. 1.1) for which the method has been demonstrated. However, the laboratory shall not report a quantitative result for a target analyte that was not included in the calibration standard(s).

5.12.4 The calibration standards must also contain the internal standards chosen for the analysis.

5.13 Matrix spiking and laboratory control sample (LCS) standards - Matrix spiking standards should be prepared from volatile organic compounds which are representative of the compounds being investigated. At a minimum, the matrix spike should include 1,1-dichloroethene, trichloroethene, chlorobenzene, toluene, and benzene. The matrix spiking solution should contain compounds that are expected to be found in the types of samples to be analyzed.

5.13.1 Some permits may require the spiking of specific compounds of interest, especially if polar compounds are a concern, since the spiking compounds listed above would not be representative of such compounds. The standard should be prepared in methanol, with each compound present at a concentration of 250 µg/10.0 mL.

5.13.2 The spiking solutions should not be prepared from the same standards as the calibration standards. However, the same spiking standard prepared for the matrix spike may be used for the LCS.

5.13.3 If a more sensitive mass spectrometer is employed to achieve lower detection levels, more dilute matrix spiking solutions may be required.

5.14 Great care must be taken to maintain the integrity of all standard solutions. It is recommended all standards in methanol be stored at -10°C or less, in amber bottles with PTFE-lined screw-caps.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

See the introductory material to this chapter, Organic Analytes, Sec. 4.1.

7.0 PROCEDURE

7.1 Various alternative methods are provided for sample introduction. All internal standards, surrogates, and matrix spiking compounds (when applicable) must be added to the samples before introduction into the GC/MS system. Consult the sample introduction method for the procedures by which to add such standards.

7.1.1 Direct injection - This includes: injection of an aqueous sample containing a very high concentration of analytes; injection of aqueous concentrates from Method 5031 (azeotropic distillation); and injection of a waste oil diluted 1:1 with hexadecane (Method 3585). Direct injection of aqueous samples (non-concentrated) has very limited applications. It is only used for the determination of volatiles at the toxicity characteristic (TC) regulatory limits or at concentrations in excess of 10,000 µg/L. It may also be used in conjunction with the test for ignitability in aqueous samples (along with Methods 1010 and 1020), to determine if alcohol is present at greater than 24%.

7.1.2 Purge-and-trap - This includes purge-and-trap for aqueous samples (Method 5030) and purge-and-trap for solid samples (Method 5035). Method 5035 also provides techniques for extraction of high concentration solid and oily waste samples by methanol (and other water-miscible solvents) with subsequent purge-and-trap from an aqueous matrix using Method 5030.

7.1.2.1 Traditionally, the purge-and-trap of aqueous samples is performed at ambient temperature, while purging of soil/solid samples is performed at 40°C, to improve purging efficiency.

7.1.2.2 Aqueous and soil/solid samples may also be purged at temperatures above those being recommended as long as all calibration standards, samples, and QC samples are purged at the same temperature, appropriate trapping material is used to handle the excess water, and the laboratory demonstrates acceptable method performance for the project. Purging of aqueous samples at elevated temperatures (e.g., 40°C) may improve the purging performance of many of the water soluble compounds which have poor purging efficiencies at ambient temperatures.

7.1.3 Vacuum distillation - this technique may be used for the introduction of volatile organics from aqueous, solid, or tissue samples (Method 5032) into the GC/MS system.

7.1.4 Automated static headspace - this technique may be used for the introduction of volatile organics from solid samples (Method 5021) into the GC/MS system.

7.1.5 Cartridge desorption - this technique may be for the introduction of volatile organics from sorbent cartridges (Method 5041) used in the sampling of air. The sorbent cartridges are from the volatile organics sampling train (VOST) or SMVOC (Method 0031).

7.2 Recommended chromatographic conditions

7.2.1 General conditions

Injector temperature:	200 - 225 °C
Transfer line temperature:	250 - 300 °C

7.2.2 Column 1 and Column 2 with cryogenic cooling (example chromatograms are presented in Figures 1 and 2)

Carrier gas (He) flow rate: 15 mL/min
Initial temperature: 10°C, hold for 5 minutes
Temperature program: 6°C/min to 70°C, then 15°C/min to 145°C
Final temperature: 145°C, hold until all expected compounds have eluted.

7.2.5 Direct injection - Column 2

Carrier gas (He) flow rate: 4 mL/min
Column: J&W DB-624, 70m x 0.53 mm
Initial temperature: 40°C, hold for 3 minutes
Temperature program: 8°C/min
Final temperature: 260°C, hold until all expected compounds have eluted.
Column Bake out: 75 minutes
Injector temperature: 200-225°C
Transfer line temperature: 250-300°C

7.2.6 Direct split interface - Column 4

Carrier gas (He) flow rate: 1.5 mL/min
Initial temperature: 35°C, hold for 2 minutes
Temperature program: 4°C/min to 50°C
10°C/min to 220°C
Final temperature: 220°C, hold until all expected compounds have eluted
Split ratio: 100:1
Injector temperature: 125°C

7.3 Initial calibration

Establish the GC/MS operating conditions, using the following as guidance:

Mass range: 35 - 260 amu
Scan time: 0.6 - 2 sec/scan
Source temperature: According to manufacturer's specifications
Ion trap only: Set axial modulation, manifold temperature, and emission current to manufacturer's recommendations

7.3.1 Each GC/MS system must be hardware-tuned to meet the criteria in Table 4 for a 5-50 ng injection or purging of 4-bromofluorobenzene (2- μ L injection of the BFB standard). Analyses must not begin until these criteria are met.

7.3.1.1 In the absence of specific recommendations on how to acquire the mass spectrum of BFB from the instrument manufacturer, the following approach has been shown to be useful: The mass spectrum of BFB may be acquired in the following manner. Three scans (the peak apex scan and the scans immediately preceding and following the apex) are acquired and averaged. Background subtraction is required, and must be accomplished using a single scan no more than 20 scans prior to the elution of

BFB. Do not background subtract part of the BFB peak. Alternatively, the analyst may use other documented approaches suggested by the instrument manufacturer.

7.3.1.2 Use the BFB mass intensity criteria in Table 4 as tuning acceptance criteria. Alternatively, other documented tuning criteria may be used (e.g., CLP, Method 524.2, or manufacturer's instructions), provided that method performance is not adversely affected.

NOTE: All subsequent standards, samples, MS/MSDs, LCSs, and blanks associated with a BFB analysis must use identical mass spectrometer instrument conditions.

7.3.2 Set up the sample introduction system as outlined in the method of choice (see Sec. 7.1). A different calibration curve is necessary for each method because of the differences in conditions and equipment. A set of at least five different calibration standards is necessary (see Sec. 5.12 and Method 8000). Calibration must be performed using the sample introduction technique that will be used for samples. For Method 5030, the purging efficiency for 5 mL of water is greater than for 25 mL. Therefore, develop the standard curve with whichever volume of sample that will be analyzed.

7.3.2.1 To prepare a calibration standard, add an appropriate volume of a secondary dilution standard solution to an aliquot of organic-free reagent water in a volumetric flask. Use a microsyringe and rapidly inject the alcoholic standard into the expanded area of the filled volumetric flask. Remove the needle as quickly as possible after injection. Mix by inverting the flask three times only. Discard the contents contained in the neck of the flask. Aqueous standards are not stable and should be prepared daily. Transfer 5.0 mL (or 25 mL if lower detection limits are required) of each standard to a gas tight syringe along with 10 μ L of internal standard. Then transfer the contents to the appropriate device or syringe. Some of the introduction methods may have specific guidance on the volume of calibration standard and the way the standards are transferred to the device.

7.3.2.2 The internal standards selected in Sec. 5.10 should permit most of the components of interest in a chromatogram to have retention times of 0.80 - 1.20, relative to one of the internal standards. Use the base peak ion from the specific internal standard as the primary ion for quantitation (see Table 1). If interferences are noted, use the next most intense ion as the quantitation ion.

7.3.2.3 To prepare a calibration standard for direct injection analysis of waste oil, dilute standards in hexadecane.

7.3.3 Proceed with the analysis of the calibration standards following the procedure in the introduction method of choice. For direct injection, inject 1 - 2 μ L into the GC/MS system. The injection volume will depend upon the chromatographic column chosen and the tolerance of the specific GC/MS system to water.

7.3.4 Tabulate the area response of the characteristic ions (see Table 5) against the concentration for each target analyte and each internal standard. Calculate response factors (RF) for each target analyte relative to one of the internal standards. The internal standard selected for the calculation of the RF for a target analyte should be the internal standard that has a retention time closest to the analyte being measured (Sec. 7.6.2).

The RF is calculated as follows:

$$RF = \frac{A_s \times C_{is}}{A_{is} \times C_s}$$

where:

A_s = Peak area (or height) of the analyte or surrogate.

A_{is} = Peak area (or height) of the internal standard.

C_s = Concentration of the analyte or surrogate.

C_{is} = Concentration of the internal standard.

7.3.5 System performance check compounds (SPCCs) - Calculate the mean RF for each target analyte using the five RF values calculated from the initial (5-point) calibration curve. A system performance check should be made before this calibration curve is used. Five compounds (the System Performance Check Compounds, or SPCCs) are checked for a minimum average response factor. These compounds are chloromethane; 1,1-dichloroethane; bromoform; chlorobenzene; and 1,1,2,2-tetrachloroethane. These compounds are used to check compound instability and to check for degradation caused by contaminated lines or active sites in the system. Example problems include:

7.3.5.1 Chloromethane is the most likely compound to be lost if the purge flow is too fast.

7.3.5.2 Bromoform is one of the compounds most likely to be purged very poorly if the purge flow is too slow. Cold spots and/or active sites in the transfer lines may adversely affect response. Response of the quantitation ion (m/z 173) is directly affected by the tuning of BFB at ions m/z 174/176. Increasing the m/z 174/176 ratio relative to m/z 95 may improve bromoform response.

7.3.5.3 Tetrachloroethane and 1,1-dichloroethane are degraded by contaminated transfer lines in purge-and-trap systems and/or active sites in trapping materials.

7.3.5.4 The minimum mean response factors for the volatile SPCCs are as follows:

Chloromethane	0.10
1,1-Dichloroethane	0.10
Bromoform	0.10
Chlorobenzene	0.30
1,1,2,2-Tetrachloroethane	0.30

7.3.6 Calibration check compounds (CCCs)

7.3.6.1 The purpose of the CCCs are to evaluate the calibration from the standpoint of the integrity of the system. High variability for these compounds may be indicative of system leaks or reactive sites on the column. Meeting the CCC criteria is not a substitute for successful calibration of the target analytes using one of the approaches described in Sec. 7.0 of Method 8000.

7.3.6.2 Calculate the standard deviation (SD) and relative standard deviation (RSD) of the response factors for all target analytes from the initial calibration, as follows:

$$SD = \sqrt{\frac{\sum_{i=1}^n (RF_i - \overline{RF})^2}{n-1}} \qquad RSD = \frac{SD}{\overline{RF}} \times 100$$

where:

RF_i = RF for each of the calibration standards

\overline{RF} = mean RF for each compound from the initial calibration

n = Number of calibration standards, e.g., 5

7.3.6.3 The RSD should be less than or equal to 15% for each target analyte. However, the RSD for each individual Calibration Check Compound (CCC) must be equal or less than 30%. If the CCCs are not included in the list of analytes for a project, and therefore not included in the calibration standards, refer to Sec. 7.0 of Method 8000. The CCCs are:

1,1-Dichloroethene	Toluene
Chloroform	Ethylbenzene
1,2-Dichloropropane	Vinyl chloride

7.3.6.4 If an RSD of greater than 30% is measured for any CCC, then corrective action to eliminate a system leak and/or column reactive sites is necessary before reattempting calibration.

7.3.7 Evaluation of retention times - The relative retention times of each target analyte in each calibration standard should agree within 0.06 relative retention time units. Late-eluting compounds usually have much better agreement.

7.3.8 Linearity of target analytes

7.3.8.1 If the RSD of any target analyte is 15% or less, then the response factor is assumed to be constant over the calibration range, and the average response factor may be used for quantitation (Sec. 7.7.2).

7.3.8.2 If the RSD of any target analyte is greater than 15%, refer to Sec. 7.0 of Method 8000 for additional calibration options. One of the options must be applied to GC/MS calibration in this situation, or a new initial calibration must be performed.

NOTE: Method 8000 specifies a linearity criterion of 20% RSD. That criterion pertains to GC and HPLC methods other than GC/MS. Method 8260 requires 15% RSD as evidence of sufficient linearity to employ an average response factor.

7.3.8.3 When the RSD exceeds 15%, the plotting and visual inspection of a calibration curve can be a useful diagnostic tool. The inspection may indicate analytical problems, including errors in standard preparation, the presence of active sites in the chromatographic system, analytes that exhibit poor chromatographic behavior, etc.

NOTE: The 20% RSD criteria in Method 8000 pertains to GC and HPLC methods other than GC/MS. Method 8260 requires 15% RSD.

7.4 GC/MS calibration verification - Calibration verification consists of three steps that are performed at the beginning of each 12-hour analytical shift.

7.4.1 Prior to the analysis of samples or calibration standards, inject or introduce 5-50 ng of the 4-bromofluorobenzene standard into the GC/MS system. The resultant mass spectra for the BFB must meet the criteria given in Table 4 before sample analysis begins. These criteria must be demonstrated each 12-hour shift during which samples are analyzed.

7.4.2 The initial calibration curve (Sec. 7.3) for each compound of interest should be verified once every 12 hours prior to sample analysis, using the introduction technique used for samples. This is accomplished by analyzing a calibration standard at a concentration near the midpoint concentration for the calibrating range of the GC/MS. The results from the calibration standard analysis should meet the verification acceptance criteria provided in Secs. 7.4.4 through 7.4.7.

NOTE: The BFB and calibration verification standard may be combined into a single standard as long as both tuning and calibration verification acceptance criteria for the project can be met without interferences.

7.4.3 A method blank should be analyzed after the calibration standard, or at any other time during the analytical shift, to ensure that the total system (introduction device, transfer lines and GC/MS system) is free of contaminants. If the method blank indicates contamination, then it may be appropriate to analyze a solvent blank to demonstrate that the contamination is not a result of carryover from standards or samples. See Sec. 8.0 of Method 8000 for method blank performance criteria.

7.4.4 System Performance Check Compounds (SPCCs)

7.4.4.1 A system performance check must be made during every 12-hour analytical shift. Each SPCC compound in the calibration verification standard must meet its minimum response factor (see Sec. 7.3.5.4). This is the same check that is applied during the initial calibration.

7.4.4.2 If the minimum response factors are not met, the system must be evaluated, and corrective action must be taken before sample analysis begins. Possible problems include standard mixture degradation, injection port inlet contamination, contamination at the front end of the analytical column, and active sites in the column or chromatographic system. This check must be met before sample analysis begins.

7.4.5 Calibration Check Compounds (CCCs)

7.4.5.1 After the system performance check is met, the CCCs listed in Sec. 7.3.6 are used to check the validity of the initial calibration. Use percent difference when performing the average response factor model calibration. Use percent drift when calibrating using a regression fit model. Refer to Sec. 7.0 of Method 8000 for guidance on calculating percent difference and drift.

7.4.5.2 If the percent difference or drift for each CCC is less than or equal to 20%, the initial calibration is assumed to be valid. If the criterion is not met (i.e., greater

than 20% difference or drift), for any one CCC, then corrective action must be taken prior to the analysis of samples. If the CCC's are not included in the list of analytes for a project, and therefore not included in the calibration standards, then all analytes must meet the 20% difference or drift criterion.

7.4.5.3 Problems similar to those listed under SPCCs could affect the CCCs. If the problem cannot be corrected by other measures, a new five-point initial calibration must be generated. The CCC criteria must be met before sample analysis begins.

7.4.6 Internal standard retention time - The retention times of the internal standards in the calibration verification standard must be evaluated immediately after or during data acquisition. If the retention time for any internal standard changes by more than 30 seconds from the that in the mid-point standard level of the most recent initial calibration sequence, then the chromatographic system must be inspected for malfunctions and corrections must be made, as required. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

7.4.7 Internal standard response - If the EICP area for any of the internal standards in the calibration verification standard changes by a factor of two (-50% to + 100%) from that in the mid-point standard level of the most recent initial calibration sequence, the mass spectrometer must be inspected for malfunctions and corrections must be made, as appropriate. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

7.5 GC/MS analysis of samples

7.5.1 It is highly recommended that the sample be screened to minimize contamination of the GC/MS system from unexpectedly high concentrations of organic compounds. Some of the screening options available utilizing SW-846 methods are automated headspace-GC/FID (Methods 5021/8015), automated headspace-GC/PID/ELCD (Methods 5021/8021), or waste dilution-GC/PID/ELCD (Methods 3585/8021) using the same type of capillary column. When used only for screening purposes, the quality control requirements in the methods above may be reduced as appropriate. Sample screening is particularly important when Method 8260 is used to achieve low detection levels.

7.5.2 BFB tuning criteria and GC/MS calibration verification criteria must be met before analyzing samples.

7.5.3 All samples and standard solutions must be allowed to warm to ambient temperature before analysis. Set up the introduction device as outlined in the method of choice.

7.5.4 The process of taking an aliquot destroys the validity of remaining volume of an aqueous sample for future analysis. Therefore, if only one VOA vial is provided to the laboratory, the analyst should prepare two aliquots for analysis at this time, to protect against possible loss of sample integrity. This second sample is maintained only until such time when the analyst has determined that the first sample has been analyzed properly. For aqueous samples, one 20-mL syringe could be used to hold two 5-mL aliquots. If the second aliquot is to be taken from the syringe, it must be analyzed within 24 hours. Care must be taken to prevent air from leaking into the syringe.

7.5.5 Remove the plunger from a 5-mL syringe and attach a closed syringe valve. Open the sample or standard bottle, which has been allowed to come to ambient temperature, and carefully pour the sample into the syringe barrel to just short of overflowing. Replace the syringe plunger and compress the sample. Open the syringe valve and vent any residual air while adjusting the sample volume to 5.0 mL. If lower detection limits are required, use a 25-mL syringe, and adjust the final volume to 25.0 mL.

7.5.6 The following procedure may be used to dilute aqueous samples for analysis of volatiles. All steps must be performed without delays, until the diluted sample is in a gas-tight syringe.

7.5.6.1 Dilutions may be made in volumetric flasks (10- to 100-mL). Select the volumetric flask that will allow for the necessary dilution. Intermediate dilution steps may be necessary for extremely large dilutions.

7.5.6.2 Calculate the approximate volume of organic-free reagent water to be added to the volumetric flask, and add slightly less than this quantity of organic-free reagent water to the flask.

7.5.6.3 Inject the appropriate volume of the original sample from the syringe into the flask. Aliquots of less than 1 mL are not recommended. Dilute the sample to the mark with organic-free reagent water. Cap the flask, invert, and shake three times. Repeat above procedure for additional dilutions.

7.5.6.4 Fill a 5-mL syringe with the diluted sample, as described in Sec. 7.5.5.

7.5.7 Compositing aqueous samples prior to GC/MS analysis

7.5.7.1 Add 5 mL of each sample (up to 5 samples are allowed) to a 25-mL glass syringe. Special precautions must be made to maintain zero headspace in the syringe. Larger volumes of a smaller number of samples may be used, provided that equal volumes of each sample are composited.

7.5.7.2 The samples must be cooled to 4°C or less during this step to minimize volatilization losses. Sample vials may be placed in a tray of ice during the processing.

7.5.7.3 Mix each vial well and draw out a 5-mL aliquot with the 25-mL syringe.

7.5.7.4 Once all the aliquots have been combined on the syringe, invert the syringe several times to mix the aliquots. Introduce the composited sample into the instrument, using the method of choice (see Sec. 7.1).

7.5.7.5 If less than five samples are used for compositing, a proportionately smaller syringe may be used, unless a 25-mL sample is to be purged.

7.5.8 Add 10 µL of the surrogate spiking solution and 10 µL of the internal standard spiking solution to each sample either manually or by autosampler. The surrogate and internal standards may be mixed and added as a single spiking solution. The addition of 10 µL of the surrogate spiking solution to 5 mL of aqueous sample will yield a concentration of 50 µg/L of each surrogate standard. The addition of 10 µL of the surrogate spiking solution to 5 g of a non-aqueous sample will yield a concentration of 50 µg/kg of each standard.

If a more sensitive mass spectrometer is employed to achieve lower detection levels, more dilute surrogate and internal standard solutions may be required.

7.5.9 Add 10 μL of the matrix spike solution (Sec. 5.13) to a 5-mL aliquot of the sample chosen for spiking. Disregarding any dilutions, this is equivalent to a concentration of 50 $\mu\text{g/L}$ of each matrix spike standard.

7.5.9.1 Follow the same procedure in preparing the laboratory control sample (LCS), except the spike is added to a clean matrix. See Sec. 8.4 and Method 5000 for more guidance on the selection and preparation of the matrix spike and the LCS.

7.5.9.2 If a more sensitive mass spectrometer is employed to achieve lower detection levels, more dilute matrix spiking and LCS solutions may be required.

7.5.10 Analyze the sample following the procedure in the introduction method of choice.

7.5.10.1 For direct injection, inject 1 to 2 μL into the GC/MS system. The volume limitation will depend upon the chromatographic column chosen and the tolerance of the specific GC/MS system to water (if an aqueous sample is being analyzed).

7.5.10.2 The concentration of the internal standards, surrogates, and matrix spiking standards (if any) added to the injection aliquot must be adjusted to provide the same concentration in the 1-2 μL injection as would be introduced into the GC/MS by purging a 5-mL aliquot.

NOTE: It may be a useful diagnostic tool to monitor internal standard retention times and responses (area counts) in all samples, spikes, blanks, and standards to effectively check drifting method performance, poor injection execution, and anticipate the need for system inspection and/or maintenance.

7.5.11 If the initial analysis of the sample or a dilution of the sample has a concentration of any analyte that exceeds the initial calibration range, the sample must be reanalyzed at a higher dilution. Secondary ion quantitation is allowed only when there are sample interferences with the primary ion.

7.5.11.1 When ions from a compound in the sample saturate the detector, this analysis must be followed by the analysis of an organic-free reagent water blank. If the blank analysis is not free of interferences, then the system must be decontaminated. Sample analysis may not resume until the blank analysis is demonstrated to be free of interferences.

7.5.11.2 All dilutions should keep the response of the major constituents (previously saturated peaks) in the upper half of the linear range of the curve.

7.5.12 The use of selected ion monitoring (SIM) is acceptable in situations requiring detection limits below the normal range of full EI spectra. However, SIM may provide a lesser degree of confidence in the compound identification unless multiple ions are monitored for each compound.

7.6 Qualitative analysis

7.6.1 The qualitative identification of each compound determined by this method is based on retention time, and on comparison of the sample mass spectrum, after background correction, with characteristic ions in a reference mass spectrum. The reference mass spectrum must be generated by the laboratory using the conditions of this method. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 30% relative intensity if less than three such ions occur in the reference spectrum. Compounds are identified as present when the following criteria are met.

7.6.1.1 The intensities of the characteristic ions of a compound maximize in the same scan or within one scan of each other. Selection of a peak by a data system target compound search routine where the search is based on the presence of a target chromatographic peak containing ions specific for the target compound at a compound-specific retention time will be accepted as meeting this criterion.

7.6.1.2 The relative retention time (RRT) of the sample component is within ± 0.06 RRT units of the RRT of the standard component.

7.6.1.3 The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum. (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%.)

7.6.1.4 Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs.

7.6.1.5 Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e., a broadened peak with shoulder(s) or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important.

7.6.1.6 Examination of extracted ion current profiles of appropriate ions can aid in the selection of spectra, and in qualitative identification of compounds. When analytes coelute (i.e., only one chromatographic peak is apparent), the identification criteria may be met, but each analyte spectrum will contain extraneous ions contributed by the coeluting compound.

7.6.2 For samples containing components not associated with the calibration standards, a library search may be made for the purpose of tentative identification. The necessity to perform this type of identification will be determined by the purpose of the analyses being conducted. Data system library search routines should not use normalization routines that would misrepresent the library or unknown spectra when compared to each other.

For example, the RCRA permit or waste delisting requirements may require the reporting of non-target analytes. Only after visual comparison of sample spectra with the nearest library

searches may the analyst assign a tentative identification. Use the following guidelines for making tentative identifications:

- (1) Relative intensities of major ions in the reference spectrum (ions greater than 10% of the most abundant ion) should be present in the sample spectrum.
- (2) The relative intensities of the major ions should agree within $\pm 20\%$. (Example: For an ion with an abundance of 50% in the standard spectrum, the corresponding sample ion abundance must be between 30 and 70%).
- (3) Molecular ions present in the reference spectrum should be present in the sample spectrum.
- (4) Ions present in the sample spectrum but not in the reference spectrum should be reviewed for possible background contamination or presence of coeluting compounds.
- (5) Ions present in the reference spectrum but not in the sample spectrum should be reviewed for possible subtraction from the sample spectrum because of background contamination or coeluting peaks. Data system library reduction programs can sometimes create these discrepancies.

7.7 Quantitative analysis

7.7.1 Once a compound has been identified, the quantitation of that compound will be based on the integrated abundance from the EICP of the primary characteristic ion. The internal standard used shall be the one nearest the retention time of that of a given analyte.

7.7.2 If the RSD of a compound's response factors is 15% or less, then the concentration in the extract may be determined using the average response factor (\overline{RF}) from initial calibration data (7.3.6). See Method 8000, Sec. 7.0, for the equations describing internal standard calibration and either linear or non-linear calibrations.

7.7.3 Where applicable, the concentration of any non-target analytes identified in the sample (Sec. 7.6.2) should be estimated. The same formulae should be used with the following modifications: The areas A_x and A_{is} should be from the total ion chromatograms, and the RF for the compound should be assumed to be 1.

7.7.4 The resulting concentration should be reported indicating: (1) that the value is an estimate, and (2) which internal standard was used to determine concentration. Use the nearest internal standard free of interferences.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One and Method 8000 for specific quality control (QC) procedures. Quality control procedures to ensure the proper operation of the various sample preparation and/or sample introduction techniques can be found in Methods 3500 and 5000. Each laboratory should maintain a formal quality assurance program. The laboratory should also maintain records to document the quality of the data generated.

8.2 Quality control procedures necessary to evaluate the GC system operation are found in Method 8000, Sec. 7.0 and include evaluation of retention time windows, calibration verification and chromatographic analysis of samples. In addition, instrument QC requirements may be found in the following sections of Method 8260:

8.2.1 The GC/MS system must be tuned to meet the BFB specifications in Secs. 7.3.1 and 7.4.1.

8.2.2 There must be an initial calibration of the GC/MS system as described in Sec. 7.3.

8.2.3 The GC/MS system must meet the SPCC criteria described in Sec. 7.4.4 and the CCC criteria in Sec. 7.4.5, each 12 hours.

8.3 Initial Demonstration of Proficiency - Each laboratory must demonstrate initial proficiency with each sample preparation and determinative method combination it utilizes, by generating data of acceptable accuracy and precision for target analytes in a clean matrix. The laboratory must also repeat the following operations whenever new staff are trained or significant changes in instrumentation are made. See Method 8000, Sec. 8.0 for information on how to accomplish this demonstration.

8.4 Sample Quality Control for Preparation and Analysis - The laboratory must also have procedures for documenting the effect of the matrix on method performance (precision, accuracy, and detection limit). At a minimum, this includes the analysis of QC samples including a method blank, matrix spike, a duplicate, and a laboratory control sample (LCS) in each analytical batch and the addition of surrogates to each field sample and QC sample.

8.4.1 Before processing any samples, the analyst should demonstrate, through the analysis of a method blank, that interferences from the analytical system, glassware, and reagents are under control. Each time a set of samples is analyzed or there is a change in reagents, a method blank should be analyzed as a safeguard against chronic laboratory contamination. The blanks should be carried through all stages of sample preparation and measurement.

8.4.2 Documenting the effect of the matrix should include the analysis of at least one matrix spike and one duplicate unspiked sample or one matrix spike/matrix spike duplicate pair. The decision on whether to prepare and analyze duplicate samples or a matrix spike/matrix spike duplicate must be based on a knowledge of the samples in the sample batch. If samples are expected to contain target analytes, then laboratories may use one matrix spike and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes, laboratories should use a matrix spike and matrix spike duplicate pair.

8.4.3 A Laboratory Control Sample (LCS) should be included with each analytical batch. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS is spiked with the same analytes at the same concentrations as the matrix spike. When the results of the matrix spike analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix.

8.4.4 See Method 8000, Sec. 8.0 for the details on carrying out sample quality control procedures for preparation and analysis.

8.5 Surrogate recoveries - The laboratory must evaluate surrogate recovery data from individual samples versus the surrogate control limits developed by the laboratory. See Method 8000, Sec. 8.0 for information on evaluating surrogate data and developing and updating surrogate limits.

8.6 The experience of the analyst performing GC/MS analyses is invaluable to the success of the methods. Each day that analysis is performed, the calibration verification standard should be evaluated to determine if the chromatographic system is operating properly. Questions that should be asked are: Do the peaks look normal? Is the response obtained comparable to the response from previous calibrations? Careful examination of the standard chromatogram can indicate whether the column is still performing acceptably, the injector is leaking, the injector septum needs replacing, etc. If any changes are made to the system (e.g., the column changed), recalibration of the system must take place.

8.7 It is recommended that the laboratory adopt additional quality assurance practices for use with this method. The specific practices that are most productive depend upon the needs of the laboratory and the nature of the samples. Whenever possible, the laboratory should analyze standard reference materials and participate in relevant performance evaluation studies.

9.0 METHOD PERFORMANCE

9.1 The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the value is above zero. The MDL actually achieved in a given analysis will vary depending on instrument sensitivity and matrix effects.

9.2 This method has been tested using purge-and-trap (Method 5030) in a single laboratory using spiked water. Using a wide-bore capillary column, water was spiked at concentrations between 0.5 and 10 µg/L. Single laboratory accuracy and precision data are presented for the method analytes in Table 6. Calculated MDLs are presented in Table 1.

9.3 The method was tested using purge-and-trap (Method 5030) with water spiked at 0.1 to 0.5 µg/L and analyzed on a cryofocused narrow-bore column. The accuracy and precision data for these compounds are presented in Table 7. MDL values were also calculated from these data and are presented in Table 2.

9.4 Direct injection (Method 3585) has been used for the analysis of waste motor oil samples using a wide-bore column. Single laboratory precision and accuracy data are presented in Tables 10 and 11 for TCLP volatiles in oil. The performance data were developed by spiking and analyzing seven replicates each of new and used oil. The oils were spiked at the TCLP regulatory concentrations for most analytes, except for the alcohols, ketones, ethyl acetate and chlorobenzene which are spiked at 5 ppm, well below the regulatory concentrations. Prior to spiking, the new oil (an SAE 30-weight motor oil) was heated at 80°C overnight to remove volatiles. The used oil (a mixture of used oil drained from passenger automobiles) was not heated and was contaminated with 20 - 300 ppm of BTEX compounds and isobutanol. These contaminants contributed to the extremely high recoveries of the BTEX compounds in the used oil. Therefore, the data from the deuterated analogs of these analytes represent more typical recovery values.

9.5 Single laboratory accuracy and precision data were obtained for the Method 5035 analytes in three soil matrices: sand; a soil collected 10 feet below the surface of a hazardous landfill, called C-Horizon; and a surface garden soil. Sample preparation was by Method 5035. Each

sample was fortified with the analytes at a concentration of 4 µg/kg. These data are listed in Tables 17, 18, and 19. All data were calculated using fluorobenzene as the internal standard added to the soil sample prior to extraction. This causes some of the results to be greater than 100% recovery because the precision of results is sometimes as great as 28%.

9.5.1 In general, the recoveries of the analytes from the sand matrix are the highest, the C-Horizon soil results are somewhat less, and the surface garden soil recoveries are the lowest. This is due to the greater adsorptive capacity of the garden soil. This illustrates the necessity of analyzing matrix spike samples to assess the degree of matrix effects.

9.5.2 The recoveries of some of the gases, or very volatile compounds, such as vinyl chloride, trichlorofluoromethane, and 1,1-dichloroethene, are somewhat greater than 100%. This is due to the difficulty encountered in fortifying the soil with these compounds, allowing an equilibration period, then extracting them with a high degree of precision. Also, the garden soil results in Table 19 include some extraordinarily high recoveries for some aromatic compounds, such as toluene, xylenes, and trimethylbenzenes. This is due to contamination of the soil prior to sample collection, and to the fact that no background was subtracted.

9.6 Performance data for nonpurgeable volatiles using azeotropic distillation (Method 5031) are included in Tables 12 to 16.

9.7 Performance data for volatiles prepared using vacuum distillation (Method 5032) in soil, water, oil and fish tissue matrices are included in Tables 20 to 27.

9.8 Single laboratory accuracy and precision data were obtained for the Method 5021 analytes in two soil matrices: sand and a surface garden soil. Replicate samples were fortified with the analytes at concentrations of 10 µg/kg. These data are listed in Table 30. All data were calculated using the internal standards listed for each analyte in Table 28. The recommended internal standards were selected because they generated the best accuracy and precision data for the analyte in both types of soil.

9.8.1 If a detector other than an MS is used for analysis, consideration must be given to the choice of internal standards and surrogates. They must not coelute with any other analyte and must have similar properties to the analytes. The recoveries of the analytes are 50% or higher for each matrix studied. The recoveries of the gases or very volatile compounds are greater than 100% in some cases. Also, results include high recoveries of some aromatic compounds, such as toluene, xylenes, and trimethylbenzenes. This is due to contamination of the soil prior to sample collection.

9.8.2 The method detection limits using Method 5021 listed in Table 29 were calculated from results of seven replicate analyses of the sand matrix. Sand was chosen because it demonstrated the least degree of matrix effect of the soils studied. These MDLs were calculated utilizing the procedure described in Chapter One and are intended to be a general indication of the capabilities of the method.

9.9 The MDL concentrations listed in Table 31 were determined using Method 5041 in conjunction with Method 8260. They were obtained using cleaned blank VOST tubes and reagent water. Similar results have been achieved with field samples. The MDL actually achieved in a given analysis will vary depending upon instrument sensitivity and the effects of the matrix. Preliminary spiking studies indicate that under the test conditions, the MDLs for spiked compounds in extremely complex matrices may be larger by a factor of 500 - 1000.

9.10 The EQL of sample taken by Method 0040 and analyzed by Method 8260 is estimated to be in the range of 0.03 to 0.9 ppm (See Table 33). Matrix effects may cause the individual compound detection limits to be higher.

TABLE 3

ESTIMATED QUANTITATION LIMITS FOR VOLATILE ANALYTES^a

Estimated Quantitation Limits		
5-mL Ground Water Purge (µg/L)	25-mL Ground water Purge (µg/L)	Low Soil/Sediment ^b µg/kg
5	1	5

^a Estimated Quantitation Limit (EQL) - The lowest concentration that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operating conditions. The EQL is generally 5 to 10 times the MDL. However, it may be nominally chosen within these guidelines to simplify data reporting. For many analytes the EQL analyte concentration is selected for the lowest non-zero standard in the calibration curve. Sample EQLs are highly matrix-dependent. The EQLs listed herein are provided for guidance and may not always be achievable. See the following footnote for further guidance on matrix-dependent EQLs.

^b EQLs listed for soil/sediment are based on wet weight. Normally data are reported on a dry weight basis; therefore, EQLs will be higher, based on the percent dry weight in each sample.

Other Matrices	Factor ^c
Water miscible liquid waste	50
High concentration soil and sludge	125
Non-water miscible waste	500

^c EQL = [EQL for low soil sediment (Table 3)] x [Factor].

For non-aqueous samples, the factor is on a wet-weight basis.

TABLE 4

BFB (4-BROMOFLUOROBENZENE) MASS INTENSITY CRITERIA^a

m/z	Required Intensity (relative abundance)
50	15 to 40% of m/z 95
75	30 to 60% of m/z 95
95	Base peak, 100% relative abundance
96	5 to 9% of m/z 95
173	Less than 2% of m/z 174
174	Greater than 50% of m/z 95
175	5 to 9% of m/z 174
176	Greater than 95% but less than 101% of m/z 174
177	5 to 9% of m/z 176

^a Alternate tuning criteria may be used, (e.g. CLP, Method 524.2, or manufacturers' instructions), provided that method performance is not adversely affected.

^a Recoveries were calculated using internal standard method. Internal standard was fluorobenzene.

TABLE 8

SURROGATE SPIKE RECOVERY LIMITS FOR WATER AND SOIL/SEDIMENT SAMPLES

Surrogate Compound	Water	Soil/Sediment
4-Bromofluorobenzene ^a	86-115	74-121
Dibromofluoromethane ^a	86-118	80-120
Toluene-d ₈ ^a	88-110	81-117
Dichloroethane-d ₄ ^a	80-120	80-120

^a Single laboratory data, for guidance only.

TABLE 9

QUANTITY OF EXTRACT REQUIRED FOR ANALYSIS OF HIGH CONCENTRATION SAMPLES

Approximate Concentration Range (µg/kg)	Volume of Extract ^a
500 - 10,000	100 µL
1,000 - 20,000	50 µL
5,000 - 100,000	10 µL
25,000 - 500,000	100 µL of 1/50 dilution ^b

Calculate appropriate dilution factor for concentrations exceeding this table.

^a The volume of solvent added to 5 mL of water being purged should be kept constant. Therefore, add to the 5-mL syringe whatever volume of solvent is necessary to maintain a volume of 100 µL added to the syringe.

^b Dilute an aliquot of the solvent extract and then take 100 µL for analysis.

Allyl alcohol	1.0, 5.0, 10.0, 25.0, 100.0
Crotonaldehyde	1.0, 5.0, 10.0, 25.0, 100.0
1,4-Dioxane	1.0, 5.0, 10.0, 25.0, 100.0
Isobutyl alcohol	1.0, 5.0, 10.0, 25.0, 100.0
Methanol	1.0, 5.0, 10.0, 25.0, 100.0
Methyl ethyl ketone	1.0, 5.0, 10.0, 25.0, 100.0
N-Nitroso-di-n-butylamine	1.0, 5.0, 10.0, 25.0, 100.0
Paraldehyde	1.0, 5.0, 10.0, 25.0, 100.0
2-Picoline	1.0, 5.0, 10.0, 25.0, 100.0
Propionitrile	1.0, 5.0, 10.0, 25.0, 100.0
Pyridine	1.0, 5.0, 10.0, 25.0, 100.0
o-Toluidine	1.0, 5.0, 10.0, 25.0, 100.0

TABLE 15

CHARACTERISTIC IONS AND RETENTION TIMES FOR VOCs (METHOD 5031)

Compound	Quantitation Ion ^a	Secondary Ions	Retention Time (min) ^b
Internal Standards			
d ₈ -Isopropyl alcohol	49		1.75
d ₁₄ -Diglyme	66	98,64	9.07
d ₇ -Dimethyl formamide	50	80	9.20
Surrogates			
d ₆ -Acetone	46	64,42	1.03
d ₃ -Methanol	33	35,30	1.75
d ₃ -Acetonitrile	44	42	2.63
d ₈ -1,4-Dioxane	96	64,34	3.97
d ₅ -Pyridine	84	56,79	6.73
d ₅ -Phenol ^c	99	71	15.43
Target Compounds			
Acetone	43	58	1.05
Methanol	31	29	1.52
Methyl ethyl ketone	43	72,57	1.53
Methacrylonitrile ^c	67	41	2.38
Acrylonitrile	53	52,51	2.53
Acetonitrile	41	40,39	2.73
Methyl isobutyl ketone ^c	85	100,58	2.78
Propionitrile	54	52,55	3.13
Crotonaldehyde	41	70	3.43
1,4-Dioxane	58	88,57	4.00
Paraldehyde	45	89	4.75
Isobutyl alcohol	43	33,42	5.05
Allyl alcohol	57	39	5.63
Pyridine	79	50,52	6.70
2-Picoline	93	66	7.27
N-Nitroso-di-n-butylamine	84	116	12.82
Aniline ^c	93	66,92	13.23
o-Toluidine	106	107	13.68
Phenol ^c	94	66,65	15.43

^a These ions were used for quantitation in selected ion monitoring.

^b GC column: DB-Wax, 30 meter x 0.53 mm, 1 µm film thickness.
Oven program: 45°C for 4 min, increased to 220°C at 12°C/min.

^c Compound removed from target analyte list due to poor accuracy and precision.

TABLE 16

METHOD ACCURACY AND PRECISION BY MEAN PERCENT RECOVERY AND PERCENT RELATIVE STANDARD DEVIATION^a (METHOD 5031 - MACRODISTILLATION TECHNIQUE)
(Single Laboratory and Single Operator)

Compound	25 ppb Spike		100 ppb Spike		500 ppb Spike	
	Mean %R	%RSD	Mean %R	%RSD	Mean %R	%RSD
d ₆ -Acetone	66	24	69	14	65	16
d ₃ -Acetonitrile	89	18	80	18	70	10
d ₈ -1,4-Dioxane	56	34	58	11	61	18
d ₃ -Methanol	43	29	48	19	56	14
d ₅ -Pyridine	83	6.3	84	7.8	85	9.0
Acetone	67	45	63	14	60	14
Acetonitrile	44	35	52	15	56	15
Acrylonitrile	49	42	47	27	45	27
Allyl alcohol	69	13	70	9.7	73	10
Crotonaldehyde	68	22	68	13	69	13
1,4-Dioxane	63	25	55	16	54	13
Isobutyl alcohol	66	14	66	5.7	65	7.9

^a Results are for 10 min. distillations times, and condenser temperature held at -10°C. A 30 m x 0.53 mm ID stable wax column with a 1 µm film thickness was used for chromatography. Standards and samples were replicated and precision value reflects the propagated errors. Each analyte was spiked at 50 ppb. Vacuum distillation efficiencies (Method 5032) are modified by internal standard corrections. Method 8260 internal standards may introduce bias for some analytes. See Method 5032 to identify alternate internal standards with similar efficiencies to minimize bias.

^b Soil samples spiked with 0.2 mL water containing analytes and then 5 mL water added to make slurry.

^c Soil sample + 1 g cod liver oil, spiked with 0.2 mL water containing analytes.

^d Soil samples + 1 g cod liver oil, spiked as above with 5 mL of water added to make slurry.

^e Interference by co-eluting compounds prevented accurate measurement of analyte.

^f Contamination of sample matrix by analyte prevented assessment of efficiency.

^a Results are for 10 min. distillation times and condenser temperature held at -10°C. Five replicate 10-g aliquots of fish spiked at 25 ppb were analyzed using GC/MS external standard quantitation. A 30 m x 0.53 mm ID stable wax column with a 1 µm film thickness was used for chromatography. Standards were replicated and results reflect 1 sigma propagated standard deviation.

^b No analyses.

^c Contamination of sample matrix by analyte prevented accurate assessment of analyte efficiency.

^d Interfering by co-eluting compounds prevented accurate measurement of analyte.

TABLE 31 (cont.)

- * The method detection limit (MDL) is defined in Chapter One. The detection limits cited above were determined according to 40 CFR, Part 136, Appendix B, using standards spiked onto clean VOST tubes. Since clean VOST tubes were used, the values cited above represent the best that the methodology can achieve. The presence of an emissions matrix will affect the ability of the methodology to perform at its optimum level.
- ** Boiling Point greater than 130°C. Not appropriate for quantitative sampling by Method 0030.

Method 9010B, 9010C, 9012A and 9013

METHOD 9010B

TOTAL AND AMENABLE CYANIDE: DISTILLATION

1.0 SCOPE AND APPLICATION

1.1 Method 9010 is reflux-distillation procedure used to extract soluble cyanide salts and many insoluble cyanide complexes from wastes and leachates. It is based on the decomposition of nearly all cyanides by a reflux distillation procedure using a strong acid and a magnesium catalyst. Cyanide, in the form of hydrocyanic acid (HCN) is purged from the sample and captured into an alkaline scrubber solution. The concentration of cyanide in the scrubber solution is then determined by Method 9014 or Method 9213. Method 9010 may be used as a reflux-distillation procedure for both total cyanide and cyanide amenable to chlorination. The "reactive" cyanide content of a waste, that is, the cyanide content that could generate toxic fumes when exposed to mild acidic conditions, is not determined by this method. Refer to Chapter Seven of SW-846 for the additional information on reactive cyanide.

1.2 This method was designed to address the problem of "trace" analyses (<1000 ppm). The method may also be used for "minor" (1000 ppm - 10,000 ppm) and "major" (>10,000 ppm) analyses by adapting the appropriate sample dilution. However, the amount of sodium hydroxide in the standards and the sample analyzed must be the same.

2.0 SUMMARY OF METHOD

2.1 The cyanide, as hydrocyanic acid (HCN), is released from samples containing cyanide by means of a reflux-distillation operation under acidic conditions and absorbed in a scrubber containing sodium hydroxide solution. The cyanide concentration in the absorbing solution is then determined colorimetrically or titrimetrically by Method 9014 or by ion-selective electrode by Method 9213.

3.0 INTERFERENCES

3.1 Interferences are eliminated or reduced by using the distillation procedure. Chlorine and sulfide are interferences in Method 9010.

3.2 Oxidizing agents such as chlorine decompose most cyanides. Chlorine interferences can be removed by adding an excess of sodium arsenite to the waste prior to preservation and storage of the sample to reduce the chlorine to chloride which does not interfere.

3.3 Sulfide interference can be removed by adding an excess of bismuth nitrate to the waste (to precipitate the sulfide) before distillation. Samples that contain hydrogen sulfide, metal sulfides, or other compounds that may produce hydrogen sulfide during the distillation should be treated by the addition of bismuth nitrate.

3.4 High results may be obtained for samples that contain nitrate and/or nitrite. During the distillation, nitrate and nitrite will form nitrous acid, which will react with some organic compounds to form oximes. These compounds once formed will decompose under test conditions to generate HCN. The possibility of interference of nitrate and nitrite is eliminated by pretreatment with sulfamic acid just before distillation. Nitrate and nitrite are interferences when present at levels higher than 10 mg/L and in conjunction with certain organic compounds.

3.5 Thiocyanate is reported to be an interference when present at very high levels. Levels of 10 mg/L were not found to interfere.

3.6 Fatty acids, detergents, surfactants, and other compounds may cause foaming during the distillation when they are present in high concentrations and may make the endpoint for the titrimetric determination difficult to detect. Refer to Sec. 6.8 for an extraction procedure to eliminate this interference.

4.0 APPARATUS AND MATERIALS

4.1 Reflux distillation apparatus such as shown in Figure 1 or Figure 2. The boiling flask should be of one liter size with inlet tube and provision for condenser. The gas scrubber may be a 270-mL Fisher-Milligan scrubber (Fisher, Part No. 07-513) or equivalent. The reflux apparatus may be a Wheaton 377160 distillation unit or equivalent.

4.2 Hot plate stirrer/heating mantle.

4.3 pH meter.

4.4 Amber light.

4.5 Vacuum source.

4.6 Refrigerator.

4.7 Erlenmeyer flask - 500 mL.

4.8 KI starch paper.

4.9 Class A volumetric flasks-1000,250, and 100 mL.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Reagents for sample collection, preservation, and handling

5.3.1 Sodium arsenite (0.1N), NaAsO_2 . Dissolve 3.2 g NaAsO_2 in 250 mL water.

5.3.2 Ascorbic acid, $\text{C}_6\text{H}_8\text{O}_6$.

5.3.3 Sodium hydroxide solution (50%), NaOH . Commercially available.

5.3.4 Acetic acid (1.6M) CH_3COOH . Dilute one part of concentrated acetic acid with 9 parts of water.

5.3.5 2,2,4-Trimethylpentane, C_8H_{18} .

5.3.6 Hexane, C_6H_{14} .

5.3.7 Chloroform, CHCl_3 .

5.4 Reagents for cyanides amenable to chlorination

5.4.1 Calcium hypochlorite solution (0.35M), $\text{Ca}(\text{OCl})_2$. Combine 5 g of calcium hypochlorite and 100 mL of water. Shake before using.

5.4.2 Sodium hydroxide solution (1.25N), NaOH . Dissolve 50 g of NaOH in 1 liter of water.

5.4.3 Sodium arsenite (0.1N). See Section 5.3.1.

5.4.4 Potassium iodide starch paper.

5.5 Reagents for distillation

5.5.1 Sodium hydroxide (1.25N). See Section 5.4.2.

5.5.2 Bismuth nitrate (0.062M), $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$. Dissolve 30 g $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ in 100 mL of water. While stirring, add 250 mL of glacial acetic acid, CH_3COOH . Stir until dissolved and dilute to 1 liter with water.

5.5.3 Sulfamic acid (0.4N), $\text{H}_2\text{NSO}_3\text{H}$. Dissolve 40 g $\text{H}_2\text{NSO}_3\text{H}$ in 1 liter of water.

5.5.4 Sulfuric acid (18N), H_2SO_4 . Slowly and carefully add 500 mL of concentrated H_2SO_4 to 500 mL of water.

5.5.5 Magnesium chloride solution (2.5M), $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$. Dissolve 510 g of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ in 1 liter of water.

5.5.6 Lead acetate paper.

5.5.7 Stock potassium cyanide solutions - Refer to Method 9014 for the preparation of stock cyanide solutions and calibration standards.

6.0 SAMPLE COLLECTION, PRESERVATION AND HANDLING

6.1 All samples must be collected using a sampling plan that addresses the considerations discussed in Chapter Nine.

6.2 Samples should be collected in plastic or glass containers. All containers must be thoroughly cleaned and rinsed.

6.3 Oxidizing agents such as chlorine decompose most cyanides. To determine whether oxidizing agents are present, test a drop of the sample with potassium iodide-starch test paper. A blue color indicates the need for treatment. Add 0.1N sodium arsenite solution a few mL at a time until a drop of sample produces no color on the indicator paper. Add an additional 5 mL of sodium arsenite solution for each liter of sample. Ascorbic acid can be used as an alternative although it is not as effective as arsenite. Add a few crystals of ascorbic acid at a time until a drop of sample produces no color on the indicator paper. Then add an additional 0.6 g of ascorbic acid for each liter of sample volume.

6.4 Aqueous samples must be preserved by adding 50% sodium hydroxide until the pH is greater than or equal to 12 at the time of collection.

6.5 Samples should be chilled to 4°C.

6.6 When properly preserved, cyanide samples can be stored for up to 14 days prior to sample preparation steps.

6.7 Solid and oily wastes may be extracted prior to analysis by method 9013. It uses a dilute NaOH solution (pH = 12) as the extractant. This yields extractable cyanide.

6.8 If fatty acids, detergents, and surfactants are a problem, they may be extracted using the following procedure. Acidify the sample with acetic acid (1.6M) to pH 6.0 to 7.0.

CAUTION: This procedure can produce lethal HCN gas.

Extract with isooctane, hexane, or chloroform (preference in order named) with solvent volume equal to 20% of the sample volume. One extraction is usually adequate to reduce the compounds below the interference level. Avoid multiple extractions or a long contact time at low pH in order to keep the loss of HCN at a minimum. When the extraction is completed, immediately raise the pH of the sample to above 12 with 50% NaOH solution.

7.0 PROCEDURE

7.1 Pretreatment for cyanides amenable to chlorination

7.1.1 This test must be performed under amber light. $K_3[Fe-(CN)_6]$ may decompose under UV light and hence will test positive for cyanide amenable to chlorination if exposed to fluorescent lighting or sunlight. Two identical sample aliquots are required to determine cyanides amenable to chlorination.

7.1.2 To one 500 mL sample or to a sample diluted to 500 mL, add calcium hypochlorite solution dropwise while agitating and maintaining the pH between 11 and 12 with 1.25N sodium hydroxide until an excess of chlorine is present as indicated by KI-starch paper turning blue. The sample will be subjected to alkaline chlorination by this step.

CAUTION: The initial reaction product of alkaline chlorination is the very toxic gas cyanogen chloride; therefore, it is necessary that this reaction be performed in a hood.

7.1.3 Test for excess chlorine with KI-starch paper and maintain this excess for one hour with continuous agitation. A distinct blue color on the test paper indicates a sufficient chlorine level. If necessary, add additional calcium hypochlorite solution.

7.1.4 After one hour, add 1 mL portions of 0.1N sodium arsenite until KI-starch paper shows no residual chlorine. Add 5 mL of excess sodium arsenite to ensure the presence of excess reducing agent.

7.1.5 Analyze the total cyanide concentration of both the chlorinated and the unchlorinated samples by Method 9014 or 9213. The difference between the total cyanide concentration in the chlorinated and unchlorinated samples is equal to the cyanide amenable to chlorination.

7.2 Distillation Procedure

7.2.1 Place 500 mL of sample, or sample diluted to 500 mL in the one liter boiling flask. Pipet 50 mL of 1.25N sodium hydroxide into the gas scrubber. If the apparatus in Figure 1 is used, add water until the spiral is covered. Connect the boiling flask, condenser, gas scrubber and vacuum trap.

7.2.2 Start a slow stream of air entering the boiling flask by adjusting the vacuum source. Adjust the vacuum so that approximately two bubbles of air per second enter the boiling flask through the air inlet tube.

7.2.3 If samples are known or suspected to contain sulfide, add 50 mL of 0.062M bismuth nitrate solution through the air inlet tube. Mix for three minutes. Use lead acetate paper to check the sample for the presence of sulfide. A positive test is indicated by a black color on the paper.

7.2.4 If samples are known or suspected to contain nitrate or nitrite, or if bismuth nitrate was added to the sample, add 50 mL of 0.4N sulfamic acid solution through the air inlet tube. Mix for three minutes.

Note: Excessive use of sulfamic acid could create method bias.

7.2.5 Slowly add 50 mL of 18N sulfuric acid through the air inlet tube. Rinse the tube with water and allow the airflow to mix the flask contents for three minutes. Add 20 mL of 2.5M magnesium chloride through the air inlet and wash the inlet tube with a stream of water.

7.2.6 Heat the solution to boiling. Reflux for one hour. Turn off heat and continue the airflow for at least 15 minutes. After cooling the boiling flask, and closing the vacuum source, disconnect the gas scrubber.

7.2.7 Transfer the solution from the scrubber into a 250-mL volumetric flask. Rinse the scrubber into the volumetric flask. Dilute to volume with water.

7.2.8 Proceed to the cyanide determinative methods given in Methods 9014 or 9213. If the distillates are not analyzed immediately, they should be stored at 4°C in tightly sealed flasks.

8.0 QUALITY CONTROL

8.1 All quality control data should be maintained and available for easy reference or inspection.

8.2 Employ a minimum of one reagent blank per analytical batch or one in every 20 samples to determine if contamination or any memory effects are occurring.

8.3 Analyze check standards with every analytical batch of samples. If the standards are not within 15% of the expected value, then the samples must be reanalyzed.

8.4 Run one replicate sample for every 20 samples. A replicate sample is a sample brought through the entire sample preparation and analytical process. The CV of the replicates should be 20% or less. If this criterion is not met, the samples should be reanalyzed.

8.5 Run one matrix spiked sample every 20 samples to check the efficiency of sample distillation by adding cyanide from the working standard or intermediate standard to 500 mL of sample to ensure a concentration of approximately 40 µg/L. The matrix spiked sample is brought through the entire sample preparation and analytical process.

8.6 It is recommended that at least two standards (a high and a low) be distilled and compared to similar values on the curve to ensure that the distillation technique is reliable. If distilled standards do not agree within $\pm 10\%$ of the undistilled standards, the analyst should find the cause of the apparent error before proceeding.

8.7 The method of standard additions shall be used for the analysis of all samples that suffer from matrix interferences such as samples which contain sulfides.

9.0 METHOD PERFORMANCE

9.1 The titration procedure using silver nitrate is used for measuring concentrations of cyanide exceeding 0.1 mg/L. The colorimetric procedure is used for concentrations below 1 mg/L of cyanide and is sensitive to about 0.02 mg/L.

9.2 EPA Method 335.2 (sample distillation with titration) reports that in a single laboratory using mixed industrial and domestic waste samples at concentrations of 0.06 to 0.62 mg/L CN⁻, the standard deviations for precision were ± 0.005 to ± 0.094 , respectively. In a single laboratory using mixed industrial and domestic waste samples at concentrations of 0.28 and 0.62 mg/L CN⁻, recoveries (accuracy) were 85% and 102%, respectively.

9.3 In two additional studies using surface water, ground water, and landfill leachate samples, the titration procedure was further evaluated. The concentration range used in these studies was 0.5 to 10 mg/L cyanide. The detection limit was found to be 0.2 mg/L for both total and amenable cyanide determinations. The precision (CV) was 6.9 and 2.6 for total cyanide determinations and 18.6 and 9.1 for amenable cyanide determinations. The mean recoveries were 94% and 98.9% for total cyanide, and 86.7% and 97.4% for amenable cyanide.

METHOD 9010B

TOTAL AND AMENABLE CYANIDE: DISTILLATION

This Page Intentionally Left Blank

METHOD 9010C

TOTAL AND AMENABLE CYANIDE: DISTILLATION

1.0 SCOPE AND APPLICATION

1.1 This method is a reflux-distillation procedure used to extract soluble cyanide salts and many insoluble cyanide complexes from wastes and leachates. It is based on the decomposition of nearly all cyanides by a reflux distillation procedure using a strong acid and a magnesium catalyst. Cyanide, in the form of hydrocyanic acid (HCN) is purged from the sample and captured into an alkaline scrubber solution. The concentration of cyanide in the scrubber solution is then determined by Method 9014 or Method 9213. This method may be used as a reflux-distillation procedure for both total cyanide and cyanide amenable to chlorination. The "reactive" cyanide content of a waste is not determined by this method. Refer to 40 CFR 261.23 for information on the characteristic of reactivity.

1.2 This method was designed to address the problem of "trace" analyses (<1000 ppm). The method may also be used for "minor" (1000 ppm - 10,000 ppm) and "major" (>10,000 ppm) analyses by adapting the appropriate sample dilution. However, the amount of sodium hydroxide in the standards and the sample analyzed must be the same.

2.0 SUMMARY OF METHOD

2.1 The cyanide, as hydrocyanic acid (HCN), is released from samples containing cyanide by means of a reflux-distillation operation under acidic conditions and absorbed in a scrubber containing sodium hydroxide solution. The cyanide concentration in the absorbing solution is then determined colorimetrically or titrimetrically by Method 9014 or by ion-selective electrode by Method 9213.

3.0 INTERFERENCES

3.1 Interferences are eliminated or reduced by using the distillation procedure. Chlorine and sulfide are interferences in Method 9010.

3.2 Oxidizing agents such as chlorine decompose most cyanides. Chlorine interferences can be removed by adding an excess of sodium arsenite to the waste prior to preservation and storage of the sample to reduce the chlorine to chloride which does not interfere.

3.3 Sulfide interference can be removed by adding an excess of bismuth nitrate to the waste (to precipitate the sulfide) before distillation. Samples that contain hydrogen sulfide, metal sulfides, or other compounds that may produce hydrogen sulfide during the distillation should be treated by the addition of bismuth nitrate.

3.4 High results may be obtained for samples that contain nitrate and/or nitrite. During the distillation, nitrate and nitrite will form nitrous acid, which will react with some organic compounds to form oximes. These compounds once formed will decompose under test conditions to generate HCN. The possibility of interference of nitrate and nitrite is eliminated by pretreatment with sulfamic acid just before distillation. Nitrate and nitrite are interferences when present at levels higher than 10 mg/L and in conjunction with certain organic compounds.

3.5 Thiocyanate is reported to be an interference when present at very high levels. Levels of 10 mg/L were not found to interfere.

3.6 Fatty acids, detergents, surfactants, and other compounds may cause foaming during the distillation when they are present in high concentrations and may make the endpoint for the titrimetric determination difficult to detect. Refer to Sec. 6.7 for an extraction procedure to eliminate this interference.

4.0 APPARATUS AND MATERIALS

4.1 Reflux distillation apparatus such as shown in Figure 1 or Figure 2. The boiling flask should be of one liter size with inlet tube and provision for condenser. The gas scrubber may be a 270-mL Fisher-Milligan scrubber (Fisher, Part No. 07-513) or equivalent. The reflux apparatus may be a Wheaton 377160 distillation unit or equivalent.

4.2 Hot plate stirrer/heating mantle.

4.3 pH meter.

4.4 Amber light.

4.5 Vacuum source.

4.6 Refrigerator.

4.7 Erlenmeyer flask - 500 mL.

4.8 KI starch paper.

4.9 Class A volumetric flasks - 1000, 250, and 100 mL.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Reagents for sample collection, preservation, and handling

5.3.1 Sodium arsenite (0.1N), NaAsO_2 . Dissolve 3.2 g of NaAsO_2 in 250 mL water.

5.3.2 Ascorbic acid, $\text{C}_6\text{H}_8\text{O}_6$.

5.3.3 Sodium hydroxide solution (50%), NaOH . Commercially available.

5.3.4 Acetic acid (1.6M) CH_3COOH . Dilute one part of concentrated acetic acid with 9 parts of water.

5.3.5 2,2,4-Trimethylpentane, C_8H_{18} .

5.3.6 Hexane, C_6H_{14} .

5.3.7 Chloroform, CHCl_3 .

5.4 Reagents for cyanides amenable to chlorination

5.4.1 Calcium hypochlorite solution (0.35M), $\text{Ca}(\text{OCl})_2$. Combine 5 g of calcium hypochlorite and 100 mL of water. Shake before using.

5.4.2 Sodium hydroxide solution (1.25N), NaOH . Dissolve 50 g of NaOH in 1 liter of water.

5.4.3 Sodium arsenite (0.1N). See Sec. 5.3.1.

5.4.4 Potassium iodide starch paper.

5.5 Reagents for distillation

5.5.1 Sodium hydroxide (1.25N). See Sec. 5.4.2.

5.5.2 Bismuth nitrate (0.062M), $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$. Dissolve 30 g of $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ in 100 mL of water. While stirring, add 250 mL of glacial acetic acid, CH_3COOH . Stir until dissolved and dilute to 1 liter with water.

5.5.3 Sulfamic acid (0.4N), $\text{H}_2\text{NSO}_3\text{H}$. Dissolve 40 g of $\text{H}_2\text{NSO}_3\text{H}$ in 1 liter of water.

5.5.4 Sulfuric acid (18N), H_2SO_4 . Slowly and carefully add 500 mL of concentrated H_2SO_4 to 500 mL of water.

5.5.5 Magnesium chloride solution (2.5M), $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$. Dissolve 510 g of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ in 1 liter of water.

5.5.6 Lead acetate paper.

5.5.7 Stock potassium cyanide solutions -- Refer to Method 9014 for the preparation of stock cyanide solutions and calibration standards.

6.0 SAMPLE COLLECTION, PRESERVATION AND HANDLING

6.1 Samples should be collected in plastic or glass containers. All containers must be thoroughly cleaned and rinsed.

6.2 Oxidizing agents such as chlorine decompose most cyanides. To determine whether oxidizing agents are present, test a drop of the sample with potassium iodide-starch test paper. A blue color indicates the need for treatment. Add 0.1N sodium arsenite solution a few mL at a time until a drop of sample produces no color on the indicator paper. Add an additional 5 mL of sodium arsenite solution for each liter of sample. Ascorbic acid can be used

as an alternative although it is not as effective as arsenite. Add a few crystals of ascorbic acid at a time until a drop of sample produces no color on the indicator paper. Then add an additional 0.6 g of ascorbic acid for each liter of sample volume.

6.3 Aqueous samples must be preserved by adding 50% sodium hydroxide until the pH is greater than or equal to 12 at the time of collection.

6.4 Samples should be chilled to 4 °C.

6.5 When properly preserved, cyanide samples can be stored for up to 14 days prior to sample preparation steps.

6.6 Solid and oily wastes may be extracted prior to analysis by Method 9013. It uses a dilute NaOH solution (pH = 12) as the extractant. This yields extractable cyanide.

6.7 If fatty acids, detergents, and surfactants are a problem, they may be extracted using the following procedure. Acidify the sample with acetic acid (1.6M) to pH 6.0 to 7.0.

CAUTION: This procedure can produce lethal HCN gas.

Extract with isooctane, hexane, or chloroform (preference in order named) with solvent volume equal to 20% of the sample volume. One extraction is usually adequate to reduce the compounds below the interference level. Avoid multiple extractions or a long contact time at low pH in order to keep the loss of HCN at a minimum. When the extraction is completed, immediately raise the pH of the sample to above 12 with 50% NaOH solution.

7.0 PROCEDURE

7.1 Pretreatment for cyanides amenable to chlorination

7.1.1 This test must be performed under amber light. $K_3[Fe-(CN)_6]$ may decompose under UV light and hence will test positive for cyanide amenable to chlorination if exposed to fluorescent lighting or sunlight. Two identical sample aliquots are required to determine cyanides amenable to chlorination.

7.1.2 To one 500 mL sample or to a sample diluted to 500 mL, add calcium hypochlorite solution dropwise while agitating and maintaining the pH between 11 and 12 with 1.25N sodium hydroxide until an excess of chlorine is present as indicated by KI-starch paper turning blue. The sample will be subjected to alkaline chlorination by this step.

CAUTION: The initial reaction product of alkaline chlorination is the very toxic gas cyanogen chloride; therefore, it is necessary that this reaction be performed in a hood.

7.1.3 Test for excess chlorine with KI-starch paper and maintain this excess for one hour with continuous agitation. A distinct blue color on the test paper indicates a sufficient chlorine level. If necessary, add additional calcium hypochlorite solution.

7.1.4 After one hour, add 1 mL portions of 0.1N sodium arsenite until KI-starch paper shows no residual chlorine. Add 5 mL of excess sodium arsenite to ensure the presence of excess reducing agent.

7.1.5 Analyze the total cyanide concentration of both the chlorinated and the unchlorinated samples by Method 9014 or 9213. The difference between the total cyanide concentration in the chlorinated and unchlorinated samples is equal to the cyanide amenable to chlorination.

7.2 Distillation procedure

7.2.1 Place 500 mL of sample, or sample diluted to 500 mL in the one liter boiling flask. Pipet 50 mL of 1.25N sodium hydroxide into the gas scrubber. If the apparatus in Figure 1 is used, add water until the spiral is covered. Connect the boiling flask, condenser, gas scrubber and vacuum trap.

7.2.2 Start a slow stream of air entering the boiling flask by adjusting the vacuum source. Adjust the vacuum so that approximately two bubbles of air per second enter the boiling flask through the air inlet tube.

7.2.3 If samples are known or suspected to contain sulfide, add 50 mL of 0.062M bismuth nitrate solution through the air inlet tube. Mix for three minutes. Use lead acetate paper to check the sample for the presence of sulfide. A positive test is indicated by a black color on the paper.

7.2.4 If samples are known or suspected to contain nitrate or nitrite, or if bismuth nitrate was added to the sample, add 50 mL of 0.4N sulfamic acid solution through the air inlet tube. Mix for three minutes.

NOTE: Excessive use of sulfamic acid could create method bias.

7.2.5 Slowly add 50 mL of 18N sulfuric acid through the air inlet tube. Rinse the tube with water and allow the airflow to mix the flask contents for three minutes. Add 20 mL of 2.5M magnesium chloride through the air inlet and wash the inlet tube with a stream of water.

7.2.6 Heat the solution to boiling. Reflux for one hour. Turn off heat and continue the airflow for at least 15 minutes. After cooling the boiling flask, and closing the vacuum source, disconnect the gas scrubber.

7.2.7 Transfer the solution from the scrubber into a 250-mL volumetric flask. Rinse the scrubber into the volumetric flask. Dilute to volume with water.

7.2.8 Proceed to the cyanide determinative methods given in Methods 9014 or 9213. If the distillates are not analyzed immediately, they should be stored at 4 °C in tightly sealed flasks.

8.0 QUALITY CONTROL

8.1 All quality control data should be maintained and available for easy reference or inspection.

8.2 Employ a minimum of one reagent blank per analytical batch or one in every 20 samples to determine if contamination or any memory effects are occurring.

8.3 Analyze check standards with every analytical batch of samples. If the standards are not within 15% of the expected value, then the samples must be reanalyzed.

8.4 Run one replicate sample for every 20 samples. A replicate sample is a sample brought through the entire sample preparation and analytical process. The CV of the replicates should be 20% or less. If this criterion is not met, the samples should be reanalyzed.

8.5 Run one matrix spiked sample every 20 samples to check the efficiency of sample distillation by adding cyanide from the working standard or intermediate standard to 500 mL of sample to ensure a concentration of approximately 40 µg/L. The matrix spiked sample is brought through the entire sample preparation and analytical process.

8.6 It is recommended that at least two standards (a high and a low) be distilled and compared to similar values on the curve to ensure that the distillation technique is reliable. If distilled standards do not agree within $\pm 10\%$ of the undistilled standards, the analyst should find the cause of the apparent error before proceeding.

8.7 The method of standard additions shall be used for the analysis of all samples that suffer from matrix interferences such as samples which contain sulfides.

9.0 METHOD PERFORMANCE

9.1 The titration procedure using silver nitrate is used for measuring concentrations of cyanide exceeding 0.1 mg/L. The colorimetric procedure is used for concentrations below 1 mg/L of cyanide and is sensitive to about 0.02 mg/L.

9.2 EPA Method 335.2 (sample distillation with titration) reports that in a single laboratory using mixed industrial and domestic waste samples at concentrations of 0.06 to 0.62 mg/L CN^- , the standard deviations for precision were ± 0.005 to ± 0.094 , respectively. In a single laboratory using mixed industrial and domestic waste samples at concentrations of 0.28 and 0.62 mg/L CN^- , recoveries (accuracy) were 85% and 102%, respectively.

9.3 In two additional studies using surface water, ground water, and landfill leachate samples, the titration procedure was further evaluated. The concentration range used in these studies was 0.5 to 10 mg/L cyanide. The detection limit was found to be 0.2 mg/L for both total and amenable cyanide determinations. The precision (CV) was 6.9 and 2.6 for total cyanide determinations and 18.6 and 9.1 for amenable cyanide determinations. The mean recoveries were 94% and 98.9% for total cyanide, and 86.7% and 97.4% for amenable cyanide.

METHOD 9010C

TOTAL AND AMENABLE CYANIDE: DISTILLATION

This Page Intentionally Left Blank

METHOD 9012A

TOTAL AND AMENABLE CYANIDE (AUTOMATED COLORIMETRIC, WITH OFF-LINE DISTILLATION)

1.0 SCOPE AND APPLICATION

1.1 Method 9012 is used to determine the concentration of inorganic cyanide (CAS Registry Number 57-12-5) in wastes or leachate. The method detects inorganic cyanides that are present as either soluble salts or complexes. It is used to determine values for both total cyanide and cyanide amenable to chlorination. The "reactive" cyanide content of a waste, that is, the cyanide content that could generate toxic fumes when exposed to mild acidic conditions, is not distilled by Method 9012 (refer to Chapter Seven). However, Method 9012 may be used to quantify the concentration of cyanide from the reactivity test.

2.0 SUMMARY OF METHOD

2.1 The cyanide, as hydrocyanic acid (HCN), is released from samples containing cyanide by means of a reflux-distillation operation under acidic conditions and absorbed in a scrubber containing sodium hydroxide solution. The cyanide ion in the absorbing solution is then determined by automated UV colorimetry.

2.2 In the automated colorimetric measurement, the cyanide is converted to cyanogen chloride (CNCl) by reaction with Chloramine-T at a pH less than 8 without hydrolyzing to the cyanate. After the reaction is complete, color is formed on the addition of pyridine-barbituric acid reagent. The concentration of NaOH must be the same in the standards, the scrubber solutions, and any dilution of the original scrubber solution to obtain colors of comparable intensity.

3.0 INTERFERENCES

3.1 Interferences are eliminated or reduced by using the distillation procedure. Chlorine and sulfide are interferences in Method 9012.

3.2 Oxidizing agents such as chlorine decompose most cyanides. Chlorine interferences can be removed by adding an excess of sodium arsenite to the waste prior to preservation and storage of the sample to reduce the chlorine to chloride which does not interfere.

3.3 Sulfide interference can be removed by adding an excess of bismuth nitrate to the waste (to precipitate the sulfide) before distillation. Samples that contain hydrogen sulfide, metal sulfides, or other compounds that may produce hydrogen sulfide during the distillation should be treated by the addition of bismuth nitrate.

3.4 High results may be obtained for samples that contain nitrate and/or nitrite. During the distillation, nitrate and nitrite will form nitrous acid, which will react with some organic compounds to form oximes. These compounds once formed will decompose under test conditions to generate HCN. The possibility of interference of nitrate and nitrite is eliminated by pretreatment with sulfamic acid just before distillation. Nitrate and nitrite are interferences when present at levels higher than 10 mg/L and in conjunction with certain organic compounds.

3.5 Thiocyanate is reported to be an interference when present at very high levels. Levels of 10 mg/L were not found to interfere in Method 9010.

3.6 Fatty acids, detergents, surfactants, and other compounds may cause foaming during the distillation when they are present in large concentrations and will make the endpoint of the titration difficult to detect. They may be extracted at pH 6-7.

4.0 APPARATUS AND MATERIALS

4.1 Reflux distillation apparatus such as shown in Figure 1 or Figure 2. The boiling flask should be of one liter size with inlet tube and provision for condenser. The gas scrubber may be a 270-mL Fisher-Milligan scrubber (Fisher, Part No. 07-513 or equivalent). The reflux apparatus may be a Wheaton 377160 distillation unit or equivalent.

4.2 Automated continuous-flow analytical instrument with:

4.2.1 Sampler.

4.2.2 Manifold.

4.2.3 Proportioning pump.

4.2.4 Heating bath with distillation coil.

4.2.5 Distillation head.

4.2.6 Colorimeter equipped with a 15-mm flowcell and 570 nm filter.

4.2.7 Recorder.

4.3 Hot plate stirrer/heating mantle.

4.4 pH meter.

4.5 Amber light.

4.6 Vacuum source.

4.7 Refrigerator.

4.8 5 mL microburette.

4.9 7 Class A volumetric flasks - 100 and 250 mL.

4.10 Erlenmeyer flask - 500 mL.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Reagents for sample collection, preservation, and handling

5.3.1 Sodium arsenite (0.1N), NaAsO_2 . Dissolve 3.2 g NaAsO_2 in 250 mL water.

5.3.2 Ascorbic acid, $\text{C}_6\text{H}_8\text{O}_6$.

5.3.3 Sodium hydroxide solution (50%), NaOH . Commercially available.

5.3.4 Acetic acid (1.6M) CH_3COOH . Dilute one part of concentrated acetic acid with 9 parts of water.

5.3.5 2,2,4-Trimethylpentane, C_8H_{18} .

5.3.6 Hexane, C_6H_{14} .

5.3.7 Chloroform, CHCl_3 .

5.4 Reagents for cyanides amenable to chlorination

5.4.1 Calcium hypochlorite solution (0.35M), $\text{Ca}(\text{OCl})_2$. Combine 5 g of calcium hypochlorite and 100 mL of water. Shake before using.

5.4.2 Sodium hydroxide solution (1.25N), NaOH . Dissolve 50 g of NaOH in 1 liter of water.

5.4.3 Sodium arsenite (0.1N). See Section 5.3.1.

5.4.4 Potassium iodide starch paper.

5.5 Reagents for distillation

5.5.1 Sodium hydroxide (1.25N). See Section 5.4.2.

5.5.2 Bismuth nitrate (0.062M), $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$. Dissolve 30 g $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ in 100 mL of water. While stirring, add 250 mL of glacial acetic acid, CH_3COOH . Stir until dissolved and dilute to 1 liter with water.

5.5.3 Sulfamic acid (0.4N), $\text{H}_2\text{NSO}_3\text{H}$. Dissolve 40 g $\text{H}_2\text{NSO}_3\text{H}$ in 1 liter of water.

5.5.4 Sulfuric acid (18N), H_2SO_4 . Slowly and carefully add 500 mL of concentrated H_2SO_4 to 500 mL of water.

5.5.5 Magnesium chloride solution (2.5M), $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$. Dissolve 510 g of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ in 1 liter of water.

5.5.6 Lead acetate paper.

5.6 Reagents for automated colorimetric determination:

5.6.1 Pyridine-barbituric acid reagent: Place 15 g of barbituric acid in a 250-mL volumetric flask, add just enough reagent water to wash the sides of the flask, and wet the barbituric acid. Add 75 mL of pyridine and mix. Add 15 mL of concentrated HCl, mix, and cool to room temperature. Dilute to 250 mL with reagent water and mix. This reagent is stable for approximately six months if stored in a cool, dark place.

5.6.2 Chloramine-T solution: Dissolve 2.0 g of white, water soluble chloramine-T in 500 mL of reagent water and refrigerate until ready to use.

5.6.3 Sodium hydroxide, 1 N: Dissolve 40 g of NaOH in reagent water, and dilute to 1 liter.

5.6.4 All working standards should contain 2 mL of 1 N NaOH (Section 5.6.3) per 100 mL.

5.6.5 Dilution water and receptacle wash water (NaOH, 0.25 N): Dissolve 10.0 g NaOH in 500 mL of reagent water. Dilute to 1 liter.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must be collected using a sampling plan that addresses the considerations discussed in Chapter Nine.

6.2 Samples should be collected in plastic or glass containers. All containers must be thoroughly cleaned and rinsed.

6.3 Oxidizing agents such as chlorine decompose most cyanides. To determine whether oxidizing agents are present, test a drop of the sample with potassium iodide-starch test paper. A blue color indicates the need for treatment. Add 0.1N sodium arsenite solution a few mL at a time until a drop of sample produces no color on the indicator paper. Add an additional 5 mL of sodium arsenite solution for each liter of sample. Ascorbic acid can be used as an alternative although it is not as effective as arsenite. Add a few crystals of ascorbic acid at a time until a drop of sample produces no color on the indicator paper. Then add an additional 0.6 g of ascorbic acid for each liter of sample volume.

6.4 Aqueous samples must be preserved by adding 50% sodium hydroxide until the pH is greater than or equal to 12 at the time of collection.

6.5 Samples should be chilled to 4°C.

6.6 When properly preserved, cyanide samples can be stored for up to 14 days prior to sample preparation steps.

6.7 Solid and oily wastes may be extracted prior to analysis by Method 9013 (Cyanide Extraction Procedure for Solids and Oils). It uses a dilute NaOH solution (pH = 12) as the extractant. This yields extractable cyanide.

6.8 If fatty acids, detergents, and surfactants are a problem, they may be extracted using the following procedure. Acidify the sample with acetic acid (1.6M) to pH 6.0 to 7.0.

CAUTION: This procedure can produce lethal HCN gas.

Extract with isooctane, hexane, or chloroform (preference in order named) with solvent volume equal to 20% of the sample volume. One extraction is usually adequate to reduce the compounds below the interference level. Avoid multiple extractions or a long contact time at low pH in order to keep the loss of HCN at a minimum. When the extraction is completed, immediately raise the pH of the sample to above 12 with 50% NaOH solution.

7.0 PROCEDURE

7.1 Pretreatment for cyanides amenable to chlorination

7.1.1 This test must be performed under amber light. $K_3[Fe-(CN)_6]$ may decompose under UV light and hence will test positive for cyanide amenable to chlorination if exposed to fluorescent lighting or sunlight. Two identical sample aliquots are required to determine cyanides amenable to chlorination.

7.1.2 To one 500 mL sample or to a sample diluted to 500 mL, add calcium hypochlorite solution dropwise while agitating and maintaining the pH between 11 and 12 with 1.25N sodium hydroxide until an excess of chlorine is present as indicated by KI-starch paper turning blue. The sample will be subjected to alkaline chlorination by this step.

CAUTION: The initial reaction product of alkaline chlorination is the very toxic gas cyanogen chloride; therefore, it is necessary that this reaction be performed in a hood.

7.1.3 Test for excess chlorine with KI-starch paper and maintain this excess for one hour with continuous agitation. A distinct blue color on the test paper indicates a sufficient chlorine level. If necessary, add additional calcium hypochlorite solution.

7.1.4 After one hour, add 1 mL portions of 0.1N sodium arsenite until KI-starch paper shows no residual chlorine. Add 5 mL of excess sodium arsenite to ensure the presence of excess reducing agent.

7.1.5 Test for total cyanide as described below in both the chlorinated and the unchlorinated samples. The difference of total cyanide in the chlorinated and unchlorinated samples is the cyanide amenable to chlorination.

7.1.6 If samples are known or suspected to contain sulfide, add 50 mL of 0.062M bismuth nitrate solution through the air inlet tube. Mix for three minutes. Use lead acetate paper to check the sample for the presence of sulfide. A positive test is indicated by a black color on the paper.

7.2 Distillation Procedure

7.2.1 Place 500 mL of sample, or sample diluted to 500 mL in the one liter boiling flask. Pipet 50 mL of 1.25N sodium hydroxide into the gas scrubber. If the apparatus in Figure 1 is used, add water until the spiral is covered. Connect the boiling flask, condenser, gas scrubber and vacuum trap.

7.2.2 Start a slow stream of air entering the boiling flask by adjusting the vacuum source. Adjust the vacuum so that approximately two bubbles of air per second enter the boiling flask through the air inlet tube.

7.2.3 If samples are known or suspected to contain nitrate or nitrite, or if bismuth nitrate was added to the sample, add 50 mL of 0.4N sulfamic acid solution through the air inlet tube. Mix for three minutes.

Note: Excessive use of sulfamic acid could create method bias.

7.2.4 Slowly add 50 mL of 18N sulfuric acid through the air inlet tube. Rinse the tube with water and allow the airflow to mix the flask contents for three minutes. Add 20 mL of 2.5M magnesium chloride through the air inlet and wash the inlet tube with a stream of water.

7.2.5 Heat the solution to boiling. Reflux for one hour. Turn off heat and continue the airflow for at least 15 minutes. After cooling the boiling flask, and closing the vacuum source, disconnect the gas scrubber.

7.2.6 Transfer the solution from the scrubber into a 250-mL volumetric flask. Rinse the scrubber into the volumetric flask. Dilute to volume with water.

7.3 Automated colorimetric determination:

7.3.1 Set up the manifold in a hood or a well-ventilated area as shown in Figure 3.

7.3.2 Allow colorimeter and recorder to warm up for 30 min. Run a baseline with all reagents, feeding reagent water through the sample line.

7.3.3 Place appropriate standards in the sampler in order of increasing concentration. Complete loading of the sampler tray with unknown samples.

7.3.4 When the baseline becomes steady, begin the analysis.

7.4 Standard curve for samples without sulfide

7.4.1 Prepare a series of standards by pipetting suitable volumes of working standard potassium cyanide solution into 250-mL volumetric flasks. To each flask, add 50 mL of 1.25N sodium hydroxide and dilute to 250 mL with water. Prepare using the following table. The sodium hydroxide concentration will be 0.25N.

<u>mL of Working Standard Solution</u> <u>(1 mL = 10 µg CN⁻)</u>	<u>Concentration</u> <u>(µg CN⁻/L)</u>
0	Blank
1.0	40
2.0	80
5.0	200
10.0	400
15.0	600
20.0	800

7.4.2 After the standard solutions have been prepared according to the table above, pipet 50 mL of each standard solution into a 100-mL volumetric flask and proceed to Sections 7.3.2 and 7.3.3 to obtain absorbance values for the standard curve. The final concentrations for the standard curve will be one half of the amounts in the above table (final concentrations ranging from 20 to 400 µg/L).

7.4.3 It is recommended that at least two standards (a high and a low) be distilled and compared to similar values on the curve to ensure that the distillation technique is reliable. If distilled standards do not agree within $\pm 10\%$ of the undistilled standards, the analyst should find the cause of the apparent error before proceeding.

7.4.4 Prepare a standard curve ranging from 20 to 400 µg/L by plotting absorbance of standard versus the cyanide concentration

7.5 Standard curve for samples with sulfide

7.5.1 It is imperative that all standards be distilled in the same manner as the samples using the method of standard additions (for example, bismuth nitrate must also be added to the standards). Standards distilled by this method will give a linear curve, at low concentrations, but as the concentration increases, the recovery decreases. It is recommended that at least five standards be distilled.

7.5.2 Prepare a series of standards similar in concentration to those mentioned in Section 7.4.1 and analyze as in Section 7.3. Prepare a standard curve by plotting absorbance of standard versus the cyanide concentration.

7.6 Calculation: Prepare a standard curve by plotting peak heights of standards against their concentration values. Compute concentrations of samples by comparing sample peak heights with the standard curve.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One for specific quality control procedures.

8.2 Verify the calibration curve with an independent calibration check standard. If the standards are not within 15% of the expected value, a new recalibration curve is required. Verify the calibration curve with every sample batch by analyzing a mid-range standard.

8.3 Run one matrix spike sample for every 10 samples to check the efficiency of sample distillation. A matrix spike should be prepared by adding cyanide from the working standard or intermediate standard to 500 mL of sample to ensure a concentration of approximately 40 µg/L. Both the matrix duplicate and matrix spike duplicate are brought through the entire sample preparation and analytical process.

8.4 The method of standard additions shall be used for the analysis of all samples that suffer from matrix interferences such as samples which contain sulfides.

9.0 METHOD PERFORMANCE

9.1 Precision and accuracy data are not available at this time.

CYANIDE EXTRACTION PROCEDURE FOR SOLIDS AND OILS

1.0 SCOPE AND APPLICATION

1.1 The extraction procedure described in this method is designed for the extraction of soluble cyanides from solid and oil wastes. The method is applicable to oil, solid, and multiphase samples. This method is not applicable to samples containing insoluble cyanide compounds.

2.0 SUMMARY OF METHOD

2.1 If the waste sample contains so much solid, or solids of such a size as to interfere with agitation and homogenization of the sample mixture in the distillation flask, or so much oil or grease as to interfere with the formation of a homogeneous emulsion, the sample may be extracted with water at pH 10 or greater, and the extract distilled and analyzed by Method 9010. Samples that contain free water are filtered and separated into an aqueous component and a combined oil and solid component. The nonaqueous component may then be extracted, and an aliquot of the extract combined with an aliquot of the filtrate in proportion to the composition of the sample. Alternatively, the components may be analyzed separately, and cyanide levels reported for each component. However, if the sample solids are known to contain sufficient levels of cyanide (about 50 µg/g) as to be well above the limit of detection, the extraction step may be deleted and the solids analyzed directly by Method 9010. This can be accomplished by diluting a small aliquot of the waste solid (1-10 g) in 500 mL water in the distillation flask and suspending the slurry during distillation with a magnetic stir-bar.

3.0 INTERFERENCES

3.1 Potential interferences that may be encountered during analysis are discussed in Method 9010.

4.0 APPARATUS AND MATERIALS

4.1 Extractor - Any suitable device that sufficiently agitates a sealed container of one liter volume or greater. For the purpose of this analysis, agitation is sufficient when:

1. All sample surfaces are continuously brought into contact with extraction fluid, and
2. The agitation prevents stratification of the sample and fluid.

4.2 Buchner funnel apparatus

4.2.1 Buchner funnel - 500-mL capacity, with 1-liter vacuum filtration flask.

4.2.2 Glass wool - Suitable for filtering, 0.8 μm diameter such as Corning Pyrex 3950.

4.2.3 Vacuum source - Preferably a water driven aspirator. A valve or stopcock to release vacuum is required.

4.3 Top-loading balance - capable of weighing 0.1 g.

4.4 Separatory funnels - 500 mL.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Sodium hydroxide (50% w/v), NaOH. Commercially available.

5.4 n-Hexane, C_6H_{14} .

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must be collected using a plan that addresses the considerations discussed in Chapter 4 of this manual. See Section 6.0 of Method 9010 for additional guidance.

7.0 PROCEDURE

7.1 If the waste does not contain any free aqueous phase, go to Step 7.5. If the sample is a homogeneous fluid or slurry that does not separate or settle in the distillation flask when using a Teflon coated magnetic stirring bar but mixes so that the solids are entirely suspended, then the sample may be analyzed by Method 9010 without an extraction step.

7.2 Assemble Buchner funnel apparatus. Unroll glass filtering fiber and fold the fiber over itself several times to make a pad about 1 cm thick when lightly compressed. Cut the pad to fit the Buchner funnel. Weigh the pad, then place it in the funnel. Turn the aspirator on and wet the pad with a known amount of water.

7.3 Transfer the sample to the Buchner funnel in small aliquots, first decanting the fluid. Rinse the sample container with known amounts of water and add the rinses to the Buchner funnel. When no free water remains in the funnel, slowly open the stopcock to allow air to enter the vacuum flask. A small amount of sediment may have passed through the glass fiber pad. This will not interfere with the analysis.

7.4 Transfer the solid and the glass fiber pad to a tared weighing dish. Since most greases and oils will not pass through the fiber pad, solids, oils, and greases will be extracted together. If the filtrate includes an oil phase, transfer the filtrate to a separatory funnel. Collect and measure the volume of the aqueous phase. Transfer the oil phase to the weighing dish with the solid.

7.5 Weigh the dish containing solid, oil (if any), and filter pad. Subtract the weight of the dry filter pad. Calculate the net volume of water present in the original sample by subtracting the total volume of rinses used from the measured volume of the filtrate.

7.6 Place the following in a 1-liter wide-mouthed bottle:

500 mL water
5 mL 50% w/v NaOH
50 mL n-Hexane (if a heavy grease is present)

If the weight of the solids (Step 7.5) is greater than 25 g, weigh out a representative aliquot of 25 g and add it to the bottle; otherwise add all of the solids. Cap the bottle.

7.7 The pH of the extract must be maintained above 10 throughout the extraction step and subsequent filtration. Since some samples may release acid, the pH must be monitored as follows. Shake the extraction bottle and after one minute, check the pH. If the pH is below 12, add 50% NaOH in 5 mL increments until it is at least 12. Recap the bottle, and repeat the procedure until the pH does not drop.

7.8 Place the bottle or bottles in the tumbler, making sure there is enough foam insulation to cushion the bottle. Turn the tumbler on and allow the extraction to run for about 16 hours.

7.9 Prepare a Buchner funnel apparatus as in Step 7.2 with a glass fiber pad filter.

7.10 Decant the extract to the Buchner funnel. Full recovery of the extract is not necessary.

7.11 If the extract contains an oil phase, separate the aqueous phase using a separatory funnel. Neither the separation nor the filtration are critical, but are necessary to be able to measure the volume of the aliquot of the aqueous extract analyzed. Small amounts of suspended solids and oil emulsions will not interfere.

7.12 At this point, an aliquot of the filtrate of the original sample may be combined with an aliquot of the extract in a proportion representative of the sample. Alternatively, they may be distilled and analyzed separately and concentrations given for each phase. This is described by the following equation:

$$\frac{\text{Liquid Sample Aliquot(mL)}}{\text{Extract Aliquot(mL)}} = \frac{\text{Solid Extracted(g)}^a}{\text{Total Solid(g)}^b} \times \frac{\text{Total Sample Filtrate(mL)}^c}{\text{Total Extraction Fluid(mL)}^d}$$

^aFrom Step 7.6. Weight of solid sample used for extraction.

^bFrom Step 7.5. Weight of solids and oil phase with the dry weight of filter and tared dish subtracted.

^cIncludes volume of all rinses added to the filtrate (Steps 7.2 and 7.3).

^d500 mL water plus total volume of NaOH solution. Does not include hexane, which is subsequently removed (Step 7.11).

Alternatively, the aliquots may be distilled and analyzed separately, concentrations for each phase reported separately, and the amounts of each phase present in the sample reported separately.

8.0 QUALITY CONTROL

8.1 Refer to Method 9010.

9.0 METHOD PERFORMANCE

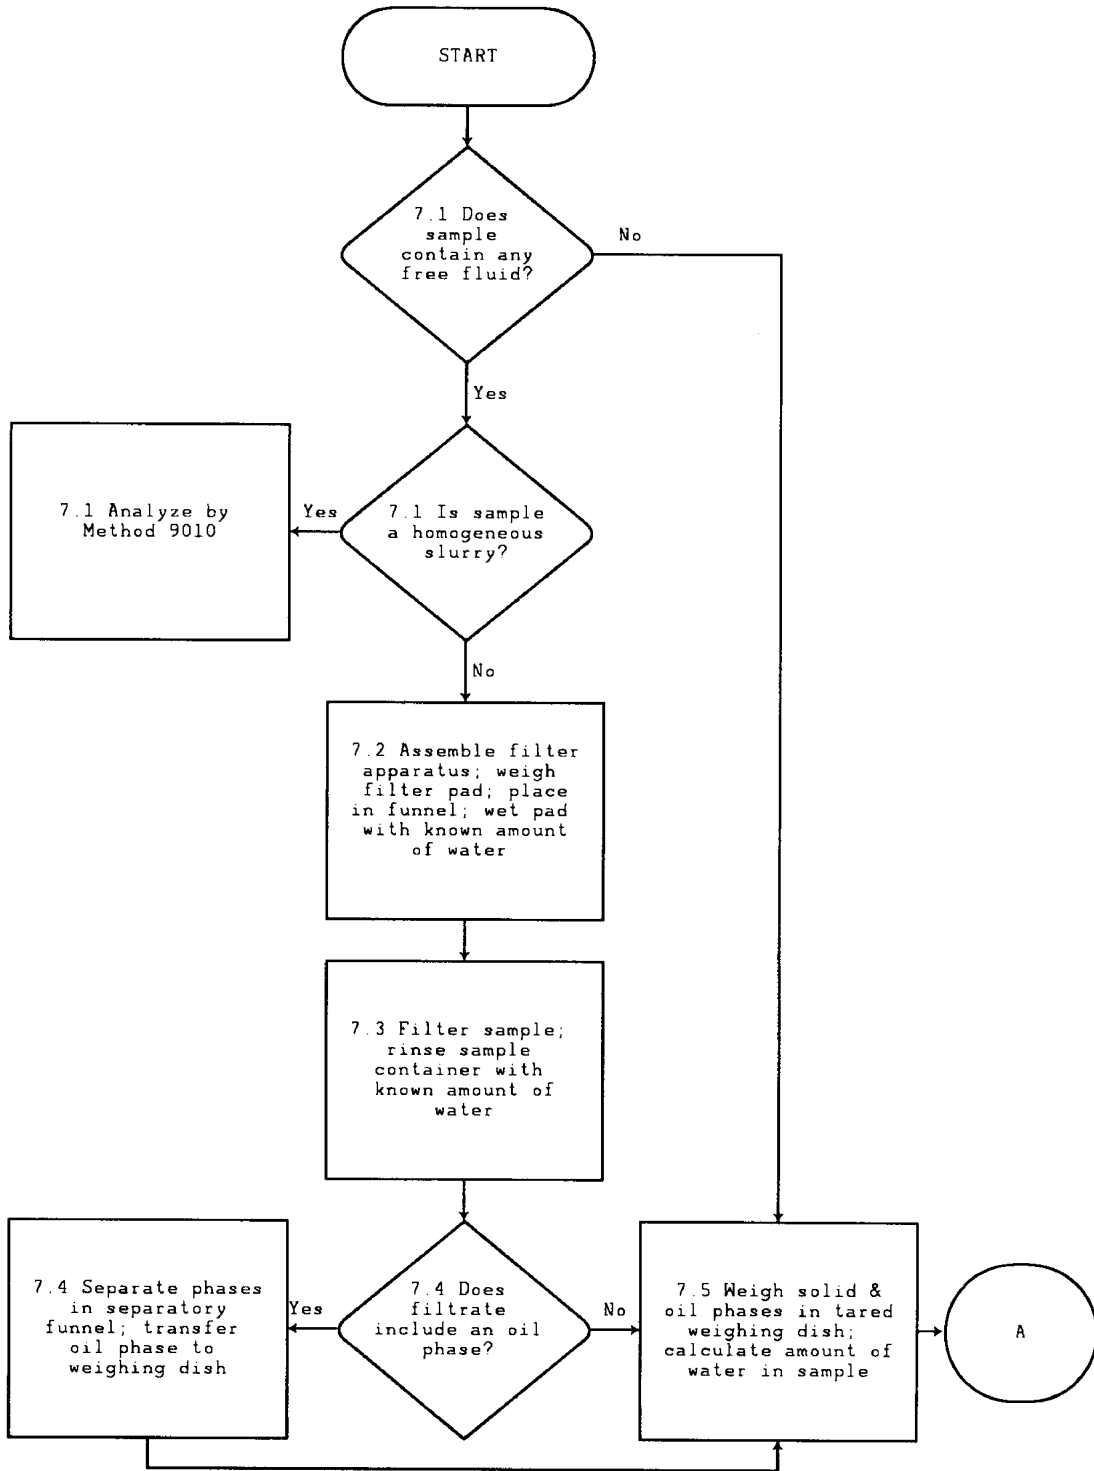

9.1 In a single laboratory study, recoveries of 60 to 90% are reported for solids and 88 to 92% for oils. The reported CVs are less than 13.

SW-846 Method 9060A

METHOD 9060A

TOTAL ORGANIC CARBON

1.0 SCOPE AND APPLICATION

1.1 This method is used to determine the concentration of organic carbon in ground water, surface and saline waters, and domestic and industrial wastes. Some restrictions are noted in Secs. 2.0 and 3.0.

1.2 This method is most applicable to measurement of organic carbon above 1 mg/L.

2.0 SUMMARY OF METHOD

2.1 Organic carbon is measured using a carbonaceous analyzer. This instrument converts the organic carbon in a sample to carbon dioxide (CO₂) by either catalytic combustion or wet chemical oxidation. The CO₂ formed is then either measured directly by an infrared detector or converted to methane (CH₄) and measured by a flame ionization detector. The amount of CO₂ or CH₄ in a sample is directly proportional to the concentration of carbonaceous material in the sample.

2.2 Carbonaceous analyzers are capable of measuring all forms of carbon in a sample. However, because of various properties of carbon-containing compounds in liquid samples, the manner of preliminary sample treatment as well as the instrument settings will determine which forms of carbon are actually measured. The forms of carbon that can be measured by this method are:

1. Soluble, nonvolatile organic carbon: e.g., natural sugars.
2. Soluble, volatile organic carbon: e.g., mercaptans, alkanes, low molecular weight alcohols.
3. Insoluble, partially volatile carbon: e.g., low molecular weight oils.
4. Insoluble, particulate carbonaceous materials: e.g., cellulose fibers.
5. Soluble or insoluble carbonaceous materials adsorbed or entrapped on insoluble inorganic suspended matter: e.g., oily matter adsorbed on silt particles.

2.3 Carbonate and bicarbonate are inorganic forms of carbon and must be separated from the total organic carbon value. Depending on the instrument manufacturer's instructions, this separation can be accomplished by either a simple mathematical subtraction, or by removing the carbonate and bicarbonate by converting them to CO₂ with degassing prior to analysis.

3.0 INTERFERENCES

3.1 Carbonate and bicarbonate carbon represent an interference under the terms of this test and must be removed or accounted for in the final calculation.

3.2 This procedure is applicable only to homogeneous samples which can be injected into the apparatus reproducibly by means of a microliter-type syringe or pipet. The openings of the syringe or pipet limit the maximum size of particle which may be included in the sample.

3.3 Removal of carbonate and bicarbonate by acidification and purging with nitrogen, or other inert gas, can result in the loss of volatile organic substances.

4.0 APPARATUS AND MATERIALS

4.1 Apparatus for blending or homogenizing samples -- Generally, a Waring-type blender is satisfactory.

4.2 Apparatus for total and dissolved organic carbon

4.2.1 Several companies manufacture analyzers for measuring carbonaceous material in liquid samples. The most appropriate system should be selected based on consideration of the types of samples to be analyzed, the expected concentration range, and the forms of carbon to be measured.

4.2.2 No specific analyzer is recommended as superior. If the technique of chemical oxidation is used, the laboratory must be certain that the instrument is capable of achieving good carbon recoveries in samples containing particulates.

5.0 REAGENTS

5.1 ASTM Type II water (ASTM D1193) -- Water should be monitored for impurities, and should be boiled and cooled to remove CO₂.

5.2 Potassium hydrogen phthalate, stock solution, 1,000 mg/L carbon -- Dissolve 0.2128 g of potassium hydrogen phthalate (primary standard grade) in Type II water and dilute to 100.0 mL.

NOTE: Sodium oxalate and acetic acid are not recommended as stock solutions.

5.3 Potassium hydrogen phthalate, standard solutions -- Prepare standard solutions from the stock solution by dilution with Type II water.

5.4 Carbonate-bicarbonate, stock solution, 1,000 mg/L carbon -- Weigh 0.3500 g of sodium bicarbonate and 0.4418 g of sodium carbonate and transfer both to the same 100-mL volumetric flask. Dissolve with Type II water.

5.5 Carbonate-bicarbonate, standard solution -- Prepare a series of standards similar to Step 5.3.

NOTE: This standard is not required by some instruments.

5.6 Blank solution -- Use the same Type II water as was used to prepare the standard solutions.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Sampling and storage of samples in glass bottles is preferable. Sampling and storage in plastic bottles such as conventional polyethylene and cubitainers is permissible if it is established that the containers do not contribute contaminating organics to the samples.

NOTE: A brief study performed in the EPA Laboratory indicated that Type II water stored in new, 1-qt cubitainers did not show any increase in organic carbon after 2 weeks' exposure.

6.2 Because of the possibility of oxidation or bacterial decomposition of some components of aqueous samples, the time between sample collection and the start of analysis should be minimized. Also, samples should be kept cool (4 °C) and protected from sunlight and atmospheric oxygen.

6.3 In instances where analysis cannot be performed within 2 hr from time of sampling, the sample is acidified (pH # 2) with HCl or H₂SO₄.

7.0 PROCEDURE

7.1 Homogenize the sample in a blender.

NOTE: To avoid erroneously high results, inorganic carbon must be accounted for. The preferred method is to measure total carbon and inorganic carbon and to obtain the organic carbon by subtraction. If this is not possible, follow Steps 7.2 and 7.3 prior to analysis; however, volatile organic carbon may be lost.

7.2 Lower the pH of the sample to 2.

7.3 Purge the sample with nitrogen for 10 min.

7.4 Follow instrument manufacturer's instructions for calibration, procedure, and calculations.

7.5 For calibration of the instrument, a series of standards should be used that encompasses the expected concentration range of the samples.

7.6 Quadruplicate analysis is required. Report both the average and the range.

8.0 QUALITY CONTROL

8.1 All quality control data should be maintained and available for easy reference or inspection.

8.2 Employ a minimum of one blank per sample batch to determine if contamination or any memory effects are occurring.

8.3 Verify calibration with an independently prepared check standard every 15 samples.

8.4 Run one spike duplicate sample for every 10 samples. A duplicate sample is a sample brought through the whole sample preparation and analytical process.

9.0 METHOD PERFORMANCE

9.1 Precision and accuracy data are available in Method 415.1 of Methods for Chemical Analysis of Water and Wastes.

Edison, New Jersey 08837

Determination of Total Organic Carbon in Sediment

1. Scope and Application

- 1.1 This method describes protocols for the determination of organic carbon in ocean sediments.
- 1.2 Although the detection limit may vary with procedure or instrument, a minimum reporting value of 100 mg/kg will be required for the ocean dumping/dredging program.
- 1.3 Several types of determinations, which are considered equivalent are presented.
- 1.4 Data are reported in mg/kg on a dry weight basis.
- 1.5 Wet combustion methods are not considered to be equivalent to the pyrolytic methods herein described.

2. Summary of Method

- 2.1 Inorganic carbon from carbonates and bicarbonates is removed by acid treatment.
- 2.2 The organic compounds are decomposed by pyrolysis in the presence of oxygen or air.
- 2.3 The carbon dioxide that is formed is determined by direct nondispersive infrared detection, flame ionization gas chromatography after catalytic conversion of the carbon dioxide to methane; thermal conductivity gas chromatography, differential thermal conductivity detection by sequential removal of water and carbon dioxide; or thermal conductivity detection following removal of water with magnesium perchlorate.

3. Sample Handling and Preservation

- 3.1 Collect sediments in glass jars with Teflon or aluminum foil. Cool and maintain at 4°C. Analyze within 14 days.

4. Interferences

- 4.1 Volatile organics in the sediments may be lost in the decarbonation step resulting in a low bias.
- 4.2 Bacterial decomposition and volatilization of the organic compounds are minimized by maintaining the sample at 4°C, analyzing within the specified holding time, and analyzing the wet sample.

5. Apparatus

5.1 Drying oven maintained at 103°-105°C.

5.2 Analytical instrument options:

5.2.1 Perkin Elmer Model 240C Elemental Analyzer or equivalent.

5.2.1.1 In this instrument, the sample from Section 7.2 is pyrolyzed under pure oxygen, water is removed by magnesium perchlorate and the carbon dioxide is removed by ascarite. The decrease in signal obtained by differential thermal conductivity detectors placed between the combustion gas stream before and after the ascarite tube is a measure of the organic carbon content.

5.2.2 Carlo Erba Model 1106-CHN Analyzer or equivalent.

5.2.2.1 In this apparatus, the sample is pyrolyzed in an induction type furnace, and the resultant carbon dioxide is chromatographically separated and analyzed by a differential thermal conductivity detector.

5.2.3 LECO Models WR-12, WR-112, or CR-12 carbon determinators or Models 600 or 800 CHN analyzers.

5.2.3.1 In the LECO WR-12, the sample is burned in a high frequency induction furnace, the carbon dioxide is selectively adsorbed at room temperature in a molecular sieve. It is subsequently released by heating and is measured by a thermal conductivity detector. The WR-112 is an upgraded WR-12 employing microprocessor electronics and a printer to replace the electronic digital voltmeter.

5.2.3.2 In the LECO CR-12 carbon determinator, the sample is combusted in oxygen, moisture and dust are removed by appropriate traps and the carbon dioxide is measured by a selective, solid state, infrared microprocessor and the carbon content is displayed on a digital readout and recorded on an integral printer.

5.2.3.3 In the LECO CHN-600 and CHN-800 elemental analyzers, the sample is burned under oxygen in a resistance furnace and the carbon dioxide is measured by a selective infrared detector.

5.2.4 Dohrman Model DC-85 Digital High Temperature TOC Analyzer

5.2.4.1 In this instrument, the sample is burned in a resistance furnace under oxygen, the interfering gases are removed by a sparger/scrubber system and the carbon dioxide is measured by non-dispersive infrared detectors and shown on a digital display in concentration units.

- 5.3 No specific analyzer is recommended as superior. The above listing is for information only and is not intended to restrict the use of other unlisted instruments capable of analyzing TOC. The instruments to be used must have the following specifications:
 - 5.3.1 A combustion boat which is heated in a stream of oxygen or air in a resistance or induction-type furnace to completely convert organic substances to CO₂ and water.
 - 5.3.2 A means to physically or by measurement technique to separate water and other interferants from CO₂.
 - 5.3.3 A means to quantitatively determine CO₂ with adequate sensitivity (100 mg/kg), and precision (25% at the 95% confidence level as demonstrated by repetitive measurements of a well mixed ocean sediment sample).
- 5.4 A strip chart or other permanent recording device to document the analysis.

6. Reagents

- 6.1 Distilled water used in preparation of standards and for dilution of samples should be ultra pure to reduce the carbon concentration of the blank.
- 6.2 Potassium hydrogen phthalate, stock solution, 100 mg carbon/liter: Dissolve 0.2128 g of potassium hydrogen phthalate (Primary standard Grade) in distilled water and dilute to 100.0 ml.
- 6.3 Potassium hydrogen phthalate, standard solutions: prepare standard solutions from the stock solution by dilutions with distilled water.
- 6.4 Phosphoric acid solution, 1:1 by volume.

7. Procedure

- 7.1 Weigh the well mixed sample (up to 500 mg) into the combustion boat or cup. Add 1:1 phosphoric acid drop-wise until effervescence stops. Heat to 75°C.
- 7.2 Analyze the residue according to the instrument manufacturer's instructions.
- 7.3 Determine percent residue on a separate sample aliquot as follows:
 - 7.3.1 Heat a clean 25 ml beaker at 103-105°C for one hour. Cool in desiccator, weigh to the nearest mg and store in desiccator until use.
 - 7.3.2 Add 1 g, weighed to the nearest mg, of an aliquot of the well-mixed sample.

7.3.3 Dry and heat in the 103-105°C oven for 1 hour. Cool in desiccator. Weigh to the nearest mg.

8. Calibration

8.1 Follow instrument manufacturer's instructions.

8.2 Prepare calibration curve plotting mg carbon vs. instrument response, using 4 standards and a blank covering the analytical range of interest.

9. Precision and Accuracy:

9.1 The precision and accuracy will differ with the various instruments and matrices and must be determined by the laboratories reporting the data. To initiate a control chart, a representative sample of well-mixed sediment should be analyzed 15 times to determine the analytical precision. Set up a control chart showing 3 times the standard deviation limits for precision.

9.2 Subsequently during analysis of environmental samples, take one sample per batch of 20 or less and run in quadruplicate. Calculate standard deviation and report with initial control chart data.

9.3 If the sample being run in quadruplicate exceeds the 3 standard deviation limit, identify error and rerun environmental samples in that batch along with the quadruplicate sample.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038

Revision Log:

Revision: 03		Effective Date: This version
Section	Justification	Changes
Revision Log	Formatting requirement per 1-P-QM-QMA-9017356	Removed revision logs up to the previous version
Throughout Document	Reflect re-identification of documents in EtQ	Replaced all prior Level 1, 2, 3, and 4 document numbers (analyses excluded) with EDR numbers
Document Title	Enhancement	Include method 8015C
Cross Reference	SOP was added to the body of the document	Added 1-P-QM-QMA-9015390
Personnel Training and Qualifications	Enhancement	Added information on DOC options and a reference to 1-P-QM-QMA-9015390.
Sample Collection, Preservation, and Handling	Reflects current industry approach	Updated refrigeration of samples from 4° ± 2°C to 0° to 6°C, not frozen
Reagents and Standards	Reflect current standards	Updated standards.
Calibration	Clarification	Updated information for clarity on total resolved SHC, total SHC and #2 Fuel calibration
Procedure	Clarification	Added information on chromatography and integration
Procedure 11.f.	Reflects current requirements	Added information on surrogate correction for NRDA work
Calculations	Requirement under NRDA to perform surrogate correction of results for SHC and PAH work	Included calculation for surrogate correction
Appendix I	Enhancement	Added chromatogram of crude oil reference standard for identification

Revision: 02		Effective Date: Nov 11, 2011
Section	Justification	Changes
Scope	Clarification	Added oil as a matrix
Sample Collection, Preservation, and Handling	Clarification	Added collection and handling instructions for oils
Reagents and Standards B.	Clarification	"NOTE" added with information/disclaimer regarding C44 standard preparation
	Enhancement	Added the ICV mix (#10).
Calibration 5.e.	Clarification	Added instructions for obtaining/entering calibration data
Calibration 7.a.	Correction	Updated CCV frequency

1-P-QM-QMA-9017309	Determining Method Detection Limits and Limits of Quantitation

Scope:

This method is applicable to the quantitation of even and odd n-alkanes in soils, waters and oil(s), along with pristane, phytane, several isoprenoids, total DRO (C10 to C28), total TPH (C9 to C40), Total Resolved Saturated Hydrocarbons (C9-C40) and Total Saturated Hydrocarbons. See Table 1 for list of analytes and limit of quantitations (LOQs). LOQs are based on annual statistical evaluation of laboratory data and are subject to change. The current Method Detection Limits (MDLs) and LOQs are maintained in the LIMS.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
--	-----------------------------------	---	--

Basic Principles:

Sample extracts in methylene chloride are analyzed by capillary gas chromatography using flame ionization detection (GC/FID). Quantitation for the analysis specific range(s) is performed by total peak area comparison of the sample pattern(s) versus the total area of the hydrocarbons. A five point calibration for each single alkane and hydrocarbon component is also utilized. Sample cleanup is performed using alumina.

Reference Modifications:

See Calibration Step 7 within this document for a reference modification.

Interferences:

Many “non-petroleum” organics will also be detected by these methods and may interfere with petroleum product characterization and/or limits of quantitation. Cleanup techniques may be employed to reduce background contribution from polar organics that are not related to target hydrocarbon fractions. These techniques include alumina or silica gel techniques. When cleanups are employed, all related batch quality control (QC) must go through the same cleanup protocol.

Safety Precautions and Waste Handling:

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

Direct exposure of skin and respiratory tract to methylene chloride must be avoided. Many sample materials to be analyzed by this method are “unknowns” and may contain toxic materials. Use good laboratory practice for handling of unknowns. Safety glasses, lab coats and gloves are required when handling samples and standards.

Revision: 3	Effective date: Oct 24, 2013	Page 4 of 24
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
--	-----------------------------------	---	--

The toxicity and carcinogenicity of each reagent used in this method has not been precisely defined. Therefore, each chemical compound must be treated as a potential health hazard. Exposure to these compounds must be reduced to the lowest possible level by whatever means are available. Good laboratory practices must be employed at all times. A reference file of material safety data sheets (MSDS) must be readily available to all analysts involved with this analysis. Waste GC vials must be placed in a designated container for storage until they are lab packed for disposal. Sample extracts and sample dilutions are disposed of by transfer to a designated container for solvent waste.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each analyst performing instrumental analysis must work with an experienced analyst for a period of time until they can independently calibrate the instrument, use the chromatography data system to set up sequences, perform the calculations, interpret chromatograms, perform instrument maintenance, and enter data into the LIMS. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an Initial Demonstration of Capability (IDOC).

The IDOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation. Various options are available for a DOC and can include four laboratory control samples or one blind sample. Refer to 1-P-QM-QMA-9015390 (LOM-SOP-ES-238) for more guidance on these options.

Sample Collection, Preservation, and Handling:

Water samples are collected in glass containers with no headspace, acidified to pH <2 with HCl and stored at 0° to 6°C, not frozen. Water must be extracted within 7 days of collection.

Revision: 3	Effective date: Oct 24, 2013	Page 5 of 24
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

Soils are collected in a glass container (minimum 150-mL) with minimal headspace and stored at 0° to 6°C, not frozen. Soils must be extracted within 14 days of collection.

Oil samples should be collected as soils (above) and are (typically) directly diluted into solvent, rather than extracted. Whether a dilution into solvent or extraction is performed, oil samples must be prepared for analysis within 14 days of collection.

Apparatus and Equipment:

1. Hewlett-Packard HP 6890 gas chromatograph, or equivalent, capable of performing direct injection capillary chromatography with temperature and pressure programming and flame ionization detection.
2. Primary column – 30 M × 0.32 mm ID fused silica capillary lined with a 0.25-µm film of ZB-5 (or equivalent).
3. GC autosampler vials – 2-mL glass with Teflon-lined crimp caps
4. Disposable Pasteur pipettes
5. Various sizes of Class “A” volumetric flasks, syringes, and pipettes
6. Analytical balance – An analytical balance capable of weighing 0.0001 g
7. Integrating system such as Chrom Perfect® by Justice Laboratory Software, or equivalent. Chrom Perfect® is a data system capable of storing and reintegrating chromatographic data and determining peak areas using a forced baseline, area summation, baseline projection, and performing baseline compensation as required.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

Reagents and Standards:

A. Reagents:

1. Methylene chloride (CH₂Cl₂) – Pesticide quality or equivalent; store at room temperature.
2. Acetone – Pesticide quality or equivalent; store at room temperature.
3. Ultra high purity hydrogen.
4. Air – Provided by a zero air generator or compressed air in tanks.

B. Standards:

1. Prepare standards using Class A volumetric flasks, pipettes, and syringes. Use an analytical balance for any solid weights.
2. Store prepared standard solutions frozen at -10 to -15°C. They are stable for 6 months unless otherwise specified.
3. Ampulated solutions are stable until the expiration date stated by the vendor under the vendors' recommended storage conditions.
4. Saturated Hydrocarbon (SHC) Stock, Accustandard, cat #DRH-0078S-R2. Contains all even and odd alkanes from C8 (*n*-octane) through C40 (*n*-tetracosane), pristane, and phytane, each at 500 µg/ml in chloroform
5. Surrogate stock, Restek cat #31097. Ortho-terphenyl at 10,000 µg/ml in methylene chloride.
6. Initial calibration standards - Use the following dilutions in methylene chloride as a guideline using the SHC stock and surrogate stock solutions to prepare 5 working calibration standards. Stable 6 months.

Revision: 3	Effective date: Oct 24, 2013	Page 7 of 24
COMPANY CONFIDENTIAL		

Approximate Concentration (ppm)	Parent solution	Volume Standard (mL)	Final Volume (mL)	Standard Prefix Code
1	SHC Stock Surrogate Stock	0.02 0.001	10	SHC_1
5	SHC Stock Surrogate Stock	0.1 0.005	10	SHC_2
10	SHC Stock Surrogate Stock	0.2 0.01	10	SHC_3
25	SHC Stock Surrogate Stock	0.5 0.025	10	SHC_4
50	SHC Stock Surrogate Stock	1.0 0.05	10	SHC_5
0.325	SHC_5	0.065	10	MDLX

7. Matrix Spiking Stock, AccuStandard cat #DRH-008S-R2 (or equivalent). Contains all alkanes, phytanes, and pristanes at 500 ppm each. Make a 20-fold dilution, using CH₂Cl₂, to prepare the working MS. Stable 6 months.
8. SHC Surrogate Spiking Stock, Restek cat #31097, containing o-terphenyl, and Restek cat #558353, containing chlorobenzene (or equivalent). Dilute 3 mL of each stock in CH₂Cl₂ and bring up to 500 mL to prepare the working surrogate spike. Stable 6 months.
9. C44 retention time neat – A C44 neat can be obtained from ChemService, catalog #0-2266 (or equivalent).
10. Stock C44 retention time check solution - Prepare a stock solution at approximately 10,000 ppm by weighing 0.05 g of neat C44 in a 5-mL volumetric flask. Bring to volume in CH₂Cl₂. Stable one year.
11. Working C44 retention time standard – Prepare a working solution at approximately 1000 ppm by placing 0.5 mL of the stock standard into a 5 mL volumetric that contains a small amount of methylene chloride. Bring to final volume. Stable one year.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

NOTE: C44 (Standard #7 - #9 from above) is prepared/analyzed upon client request only and is not part of the routine analyte list for this analysis.

12. ICV Mix – Sigma Aldrich custom mix which includes each analyte of interest at 500 µg/mL. Add 0.2 mL of stock, along with 0.01 ml of surrogate stock, to a 10 ml volumetric flask. Bring to volume with methylene chloride.

13. Crude Oil Reference Stock Standard- This is a client supplied reference standard specific to this analysis. It is typically a raw material. Accurately weight 0.2g of raw material into a 10mL volumetric flask and bring to volume with Methylene chloride. The concentration of this solution is approximately 20,000ppm. Because of the rarity of this product, it is not assigned an expiration date. It is to be used until it is consumed by operations. A chromatogram is provided in Appendix I.

14. Crude Oil Working Standard- Create a 10X dilution of the Crude Oil Reference Stock standard (see #13) by accurately measuring 1mL of the stock standard into a 10mL volumetric flask. Bring to volume with Methylene chloride. The concentration of this solution is approximately 2,000ppm. This solution does not expire. It is to be used until consumed by operations.

Crude oil can also be purchased as a certified ampulated stock from NIST. It is listed as Gulf of Mexico Crude Oil (cat.# 2779). Prepare the stock and standard in the same manner (See #13-14). This standard is to be used when a client supplied standard is not available.

Extraction and Cleanup:

See Analysis #10942, 11509, for extraction of solids and analysis 11599 for cleanup. See analysis 11596 for extraction of waters.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
--	-----------------------------------	---	--

Gas Chromatographic Conditions:

The gas chromatographic system is set to the conditions similar to those stated below. The conditions listed serve as a guideline only and are typically the optimum operating conditions. The analyst may make changes to the chromatographic conditions to improve the speed of analysis, linearity, sensitivity and/or improve the separation if initial and continuing calibration criteria and quality assurance criteria listed within this analysis document are met.

<i>Detector:</i>	FID, hydrogen at 30-35 mL/min, air at ~350 mL/min
<i>Detector Temp:</i>	320°C
<i>Oven Temp:</i>	40°C, 2 min, 8°C/min to 340°C, hold 1 min
<i>Carrier:</i>	Hydrogen at constant flow of 10 mL/min in constant flow mode
<i>Makeup Gas:</i>	N2 at 20 mL/min
<i>Injection Size:</i>	1 µL, direct injection
<i>Injection Conditions:</i>	320°C

Calibration:

1. Prior to starting a new calibration,
 - a. Change the septum on the GC and allow the system to stabilize.
 - b. Fill the autosampler.
 - c. Rinse vials with clean solvent or replace vials which appear dirty.
2. Make several injections of methylene chloride to stabilize the system.
3. If necessary, make a compensation run according to the HP manual instructions and program the GC to use the run for background subtraction.

Revision: 3	Effective date: Oct 24, 2013	Page 10 of 24
COMPANY CONFIDENTIAL		

4. Prepare a sequence using the following order of injections:

1. Conditioner (level 5 cal standard)
 2. Conditioner/methylene chloride blank
 3. Crude Oil Standard
 4. Methylene chloride blank
 5. SHC_1
 6. SHC_2
 7. SHC_3
 8. SHC_4
 9. SHC_5
 10. Methylene chloride blank
 11. 1FUL1
 12. 1FUL2
 13. 1FUL3
 14. 1FUL4
 15. 1FUL5
 16. Methylene chloride blank
 17. SHMD (MDL)
 18. ICV Standard
 19. CCV (SHC_3)
 20. Blank
 21. LCS
 22. 1234567
 23. 1234567ms
 24. 1234567msd
 - 25.-29. Continue running samples
 30. CCV (SHC_3)
- a. Continue running groups of 10 injections followed the level 3 calibration standard containing the components and surrogate standard (SHC_3)
- b. Use the conditioner injection to prime the system.
- (1) The conditioner is best utilized when the GC has not been running and there is a gap in time prior to starting a set of injections.
 - (2) The conditioner is usually a standard or sample that has already been injected.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

- c. Methylene chloride blanks may also be run to allow the GC to go through some temperature programs and/or to check the cleanliness of the system.
- d. Projects or clients may need the TPH range extended beyond C40; therefore, C44 is run at the beginning of a sequence (at client's request) to define the retention time for this alkane. No calibration is necessary for C44, it is used for retention time purposes only.

5. Initial calibration (ICAL)

- a. Calibrate the GC using five levels of the hydrocarbon/surrogate mix (SHC_1 through 5).
- b. Calibrate the individual alkanes, pristane, phytane and o-terphenyl surrogate using the individual peak responses.
- c. Since reference standards are not available for the isoprenoids, calibrate them using the next eluting normal alkane. See Appendix 1 at the end of this document for information on identifying the Isoprenoids and assigning the appropriate retention times during the initial calibration process.
- d. Isoprenoid RRT 1380 uses the response for C14; isoprenoid RRT1470 uses the response for C15; and norpristane 1650 uses the response for C17.
- e. The response factors for the DRO (C10-C28) and TPH (C9-C40) ranges are based on the sum of the areas for the hydrocarbons within the designated range versus the sum of the concentration for each hydrocarbon.

- (1) Tabulate the average response factors for each target compound of/for each target range and calculate an average. Enter this average response factor in the “Component Constant” field for the respective target range.
 - (2) For example; for DRO, tabulate the average response factors for C10 through C28, inclusive (including pristane & phytane). Calculate an average of these response factors to obtain one average response factor for the DRO range.
 - (3) Similarly, for TPH, tabulate the average response factors for C9 through C40, inclusive (including pristane & phytane). Calculate an average of these response factors to obtain one average response factor for the TPH and SHC ranges.
 - (4) For Total Resolved SHC (C9-C40), tabulate the total area from C9-C40 inclusive (including pristane & phytane) from the valley-to-valley integration. The response is calculated based on the average response factor of TPH (See #3).
 - (5) Total SHC is a total of the reportable amount of each individual analyte from the valley-to-valley integration. The datalog program is designed to perform this calculation.
- f. Use an external standard calibration for all calibrations, with average calibration factor (AVGCF) when the %RSD is $\leq 20\%$.
- g. Alternatively, when this criterion is not met, use a linear calibration curve. The correlation coefficient must be less than or equal to 0.99 for the curve to be valid. Extrapolate or force zero is not allowed. Set the zero to ignore.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

- h. If the 0.99 curve coefficient cannot be met, inspect the data points to see if one or more calibration levels appear to be an outlier. A specific calibration level may have concentrated due to solvent evaporation, or degraded over time. Reinject or remake the standard if this is the cause. Otherwise, the instrument may need maintenance. See 1-P-QM-PRO-9015447 (SOP-EP-006).
 - i. Curve types and criteria can be altered to meet client or project specific requirements, as well as any regulatory agency requirements, which may differ from those listed here.
 - j. Set up the calibration file using the area response versus concentration in mg/L.
 - k. Additionally, run five levels of #2 fuel oil individually and calibrate using the total area over the C9 to C40 retention time range.
 - (1) Use the fifth level total area response of the #2 fuel oil to define the upper end of the calibration range. (If the sample total area exceeds this, the sample must be diluted into range.)
 - (2) The full calibration, using fuel, demonstrates the linear response throughout this range of area response.
 - (3) A full #2 fuel oil 5-point curve must be run at a minimum of one time for the life of the GC column to prove linearity. If additional component calibrations are required without a column change, running a level 5 #2 fuel oil standard is sufficient to re-establish the upper end of the calibration range.
6. Analyze an initial calibration verification (ICV) after the ICAL. The ICV is an alternate source of target individual analytes. The concentration for each component must be within $\pm 20\%$ difference (%D) of the nominal concentration when compared to the calibration.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

7. Continuing calibration verification (CCV)

- a. Analyze every 10 injections, or after every batch, whichever comes first.
- b. Use the level 3 saturated hydrocarbon component standard.
- c. The concentration of the hydrocarbons and other target analytes, ranges and surrogates in the continuing calibration standard must be within $\pm 20\%$ difference (%D) of the nominal concentration when compared to the calibration.
- d. Samples must be bracketed by compliant standards.
 - (1) If they are not, they generally must be rerun (see method modification below).
 - (2) If, however, the standard following the sample is outside the $\pm 20\%$, but exhibits increasing response, the samples before it do not need to be re-injected if the target analytes are not detected.
- e. If the percent difference in the continuing calibration standard is outside $\pm 20\%$ of the nominal concentration:
 - (1) A new standard can be injected to ensure there was no problem with the injection or preparation of the standard.
 - (2) If the second injection is within limits, the preceding data can be accepted and injections can continue.
 - (3) If the subsequent standard is outside QC limits, corrective action must be taken before proceeding, which may include injector maintenance, system bake-out and/or re-calibration.

Method modification: The target analyte list for this SOP is not specifically addressed in method 8015C. Because the target analyte list is extensive, there is potential for a few target analytes to exhibit a response outside the general method 8015C requirement for 20%D. Therefore, in these cases, the analyst may evaluate the CCV and decide if reanalysis of the associated samples is necessary. For example, if the total SHC response is within +/- 20% D, but the response for one or two hydrocarbons is marginally outside +/-20% D, the overall standard is shown to be within the method criteria. Since the impact on the sample results would be minimal, analysis may continue.

8. Set the scaling of chromatograms and peak integration parameters so that a standard of fuel at the concentration of the MDL gives a pattern that is discernable from the baseline and can be integrated properly. This ensures that the quantitation limits and MDLs can be met.

9. The GC system must be within optimum operating conditions before establishing retention time (RT) windows.
 - a. Establish surrogate and hydrocarbon component peak retention times based on three injections of the CCV standard over a 72-hour period.
 - b. Calculate the standard deviation of the three absolute retention times for each individual component.
 - c. The retention time window for each component is defined as plus or minus three times the standard deviation of the absolute retention time for that component.
 - d. If the retention times (RTs) fall outside the RT windows, update the appropriate range's RTs using that standard.
 - e. RTs cannot be updated more than once per day.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

- f. If RTs are not consistent, investigate the cause and take corrective action.

Procedure:

1. Perform quantitation of samples and QC by comparing the area of all chromatographic peaks including resolved and unresolved components, eluting in the hydrocarbon range(s) specified within the analysis or by the client with the average response factor from the hydrocarbon mix calibration.
2. For the range analyses, project a horizontal baseline from beginning of the range to the end of the range.
3. For DRO, the range starts at 0.10 min before the RT of C10 up to 0.10 min after the RT for C28.
4. For TPH, the range starts at 0.1 min before the RT of C9 up to 0.10 min after the RT for C40.
5. When volatile petroleum products eluting before C9 are present, project the baseline prior to the CH₂Cl₂ solvent front.
6. Adjust the baseline to ensure accurate integration of total area in the C9-C40 range.
7. Determine the total areas for DRO and TPH from this chromatogram.
8. To quantitate the individual analytes, a second integration of the plot is done using a baseline determination that follows the baseline in a point-to-point, or valley to valley, manner around any unresolved hydrocarbon or fuel area.
 - a. A strict valley to valley integration is not used when peaks are eluting very closely.

Revision: 3	Effective date: Oct 24, 2013	Page 17 of 24
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

- b. In these cases, a common baseline under the close eluting pair is used and the two peaks are manually split.
 - c. The area for o-terphenyl surrogate is determined from this and subtracted from the total area or appropriate range result.
 - d. Due to limitations of the acquisition software, it is common for some compounds to co-elute. Effort should be made to make sure that each individual analyte is accounted for in each sample. The analyst must check the point-to-point plot and integrate each analyte appropriately so as to not bias the result of individual compounds.
 - e. Also see 1-P-QM-PRO-9015451 (SOP-EP-011), Interpretation and Integration of Chromatographic Data.
9. Compare retention times of peaks in the samples to the standard RT windows for the individual target analytes. Quantitate peaks that are present within the RT window as detections.
 10. Total SHC, Total DRO (C10-C28), Total resolved SHC, and Total TPH are reported as follows:
 - a. Total SHC = sum of the concentrations of all detections for the alkanes. Those values come from the point to point integration.
 - b. Total DRO = C10 to C28 using the integration of all area, resolved and unresolved.
 - c. Total TPH = C9 to C40 using the integration of all area, resolved and unresolved.
 - d. Total Resolved SHC = C9 to C40 using all area above the unresolved hump. (This information comes from the point to point integration and is slightly different then adding all the detections for the individuals.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

11. Calculate surrogate standard recoveries.

- a. Compare the calculated concentration to the expected concentration.
- b. Integration for the surrogate peak is done using a valley-to-valley approach rather than one horizontal baseline across the entire peak area.
- c. If the surrogates are outside QC limits, the sample may be reinjected to ensure there was no issue with the injection.
- d. If the surrogate recovery is still out of specification, the sample may need to be re-extracted.
- e. Sample extracts that are diluted may not contain surrogates that will meet the recovery requirements.
- f. If the client has indicated that the work requires compliance for NRDA (Natural Resource Damage Assessment), surrogate correction is performed (see calculation section).

12. Dilutions

- a. Perform dilutions as necessary for any truncated (“flattened”) peaks and/or to bring total sample response within the working linear range of the calibration.
- b. Dilute any sample whose total area exceeds that of the upper level fuel standard to ensure they are within the working range of the fuel calibration.
- c. Report the results for the least dilute sample where the concentration measured is within the acceptable calibration range.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038

Calculations:

1. Using AVGCF

$$\frac{\text{Sample Area}}{\text{AVGCF}} \times \frac{\text{FV}}{\text{IV or IW}} \times \text{DF} = \text{mg/L or mg/kg as received}$$

2. Using linear curve

$$[(\text{Sample Area} - Y - \text{intercept}) / \text{Slope}] \times \frac{\text{FV}}{\text{IV or IW}} \times \text{DF} = \text{mg/kg or mg/L as received}$$

Where:

Sample Area = Total area in established RT range minus surrogate area

FV = Final volume in mL

IV = Initial volume in mL

IW = Initial weight in g

DF = Dilution factor

3. Also see 1-P-QM-PRO-9015448 (SOP-EP-008) for details on calculations.
4. Client Request for Surrogate Correction - the data can be corrected based on the surrogate recovery as is required under NRDA for SHC work.
 - a. Data is only corrected for surrogate recoveries that are less than 100%
 - b. Data is only corrected for dilutions less than 10.
 - c. The result, MDL, and LOQ are corrected by dividing the result/MDL/LOQ by the recovery of the surrogate.

	Lancaster Laboratories	Document Title: Total Saturated Hydrocarbons by Method 8015C in Waters and Solids using GC/FID	Eurofins Document Reference: 1-P-QM-WI -9013038
---	-----------------------------------	---	--

d. Example calculation: $15 \div 0.95 = 15.79$

Original result of 15 mg/kg

Surrogate recovery of 95%

Final result of 15.79 mg/kg

Statistical Information/Method Performance:

Generate MDLs and LOQs according to 1-P-QM-QMA-9017309 (LOM-SOP-ES-203). Perform an MDL study on each instrument used for the analysis. Determine the MDL by taking seven spiked replicates through the entire extraction and analysis procedure. Compare and pool results to determine the final reporting MDL. The department supervisor maintains annual study data. The department supervisor requests that QA update to the LIMS as needed. Update the department database via a download from the LIMS.

Quality Assurance/Quality Control:

Each extraction batch (up to 20 samples) must contain a method blank, a laboratory control spike sample (LCS), and either an unspiked background sample (US), a matrix spike (MS), a matrix spike duplicate (MSD) or an LCS/LCSD.

See 1-P-QM-PRO-9015449 (SOP-EP-009) and 1-P-QM-PRO-9015450 (SOP-EP-010) for QC acceptance criteria and corrective action.

QC limits for surrogates, LCS/LCSD, and MS/MSD are established through statistical analysis of historical data. The limits are evaluated every 6 months and updated as needed. The limits are maintained in the LIMS for the relevant analysis numbers.

Table I – Target Analytes

Analyte	Soil LOQ (mg/kg)	Water LOQ (µg/l)
n-Nonane	0.033	1

SOP-WQ-017	Quality Control Data for Wet Chemistry

Purpose:

The purpose of this SOP is to clearly describe the process for digesting and analyzing solid samples for hexavalent chromium using SW-846 3060A and SW-846 7196A.

Scope:

This method is for the digestion and colorimetric analysis of hexavalent chromium in solid wastes. Following the digestion, the extracts are analyzed by either the colorimetric procedure contained within this SOP (SW-846 7196A), or by the Ion Chromatography procedure performed by the Instrumental Water Quality Group (SW-846 7199).

Basic Principles:

The solid sample is digested using a hot 3% sodium carbonate/2% sodium hydroxide solution and filtering through a 0.45- μ m filter. The pH of the filtrate must then be carefully adjusted. Failure to meet the pH specifications necessitates redigestion of the sample.

Definitions:

1. CCV – Continuing Calibration Verification
2. HSS – High Level Soluble Spike
3. ICV – Initial Calibration Verification
4. IS – Insoluble Matrix Spike
5. ISD – Insoluble Spike Duplicate
6. Soluble LCS – Laboratory Control Sample, referred to as LCS (5 mg/kg)
7. LCSD – Laboratory Control Sample Duplicate
8. LCSIS - LCS Insoluble Spike
9. PDS – Post Digestion Matrix Spike
10. SS – Soluble Matrix Spike

Interferences:

When analyzing a sample for hexavalent chromium, it is appropriate to determine the reducing/oxidizing tendency of each sample matrix. This is accomplished by characterizing each sample with additional parameters, such as pH, ferrous iron, sulfides, and oxidation reduction potential. Other indirect indicators of reducing/oxidizing tendency include total organic carbon, chemical oxygen demand, and biochemical oxygen demand. Analysis of these additional parameters is usually requested by the client to establish the tendency of Cr (VI) to exist in the unspiked samples and to assist in the interpretation of QC data for matrix spike recoveries outside the accepted criteria.

Magnesium chloride, in a phosphate, is added to the alkaline extraction solution to suppress possible oxidation of soluble Cr (III). One of the most insoluble forms of chromate in alkaline solution, barium chromate, requires additional heating time to affect complete dissolution in some soil matrices.

Refer to the quantification protocols for additional information on possible interferences.

Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability.

Analysts are considered proficient when they have a documented Demonstration of Capability. This usually consists of four laboratory control standards that are carried through all steps of the analysis and that meet the acceptance criteria for the LCS. Demonstration of Capability is performed annually and documentation is in each individual's training records.

Sample Collection, Preservation and Handling:

Soils are collected in an unpreserved glass container and stored at $4^{\circ} \pm 2^{\circ}\text{C}$. They must be digested within 30 days of sample collection (analysis 7825 and/or analysis 2432). Analysis of the digestate must occur within 168 hours.

Apparatus and Equipment:

1. Hot plate with magnetic stirrer
2. Vacuum filter apparatus with 0.45- μm filters – Gelman Sciences membrane 47 mm or equivalent or Whatman glass microfibre filters 42.5 mm or equivalent
3. Spectrophotometer for use at 540 nm
4. Class A glassware and pipettes – 50-, 100-, and 250-mL beakers, 50-mL graduated cylinder, 100-mL volumetric flasks, and assorted pipettes
5. Watch glass covers for 250-mL beakers
6. Thermometer (NIST traceable or equivalent)
7. Calibrated pH meter
8. Calibrated balance
9. 1-cm cell

10. Kimwipes – 1-ply white wipers (Kimberly-Clark or equivalent)
11. Analytical balance capable of weighing to .0001 g

Reagents and Standards:

Alternative weights and volumes are allowed as long as the final concentration remains the same. See LOM-SOP-ES-225 for appropriate labeling and documentation of reagents and standards preparation.

1. NaOH, Na₂CO₃, K₂HPO₄, KH₂PO₄ – Stored at room temperature, re-evaluated yearly.
2. Reagent grade water/Reagent water
3. Digestion solution – In a 2-L glass volumetric, dissolve 60.0 ± 0.05 g Na₂CO₃ and 40.0 ± 0.05 g NaOH in reagent water and dilute to 2 L. Solution expires 30 days from date of preparation. Store at room temperature. The pH of the digestion solution must be checked before use each day. Record the pH of the solution in the Laboratory Data Notebook. The pH must be 11.5 or greater; if not, discard.

NOTE: For account #10651, 500 mL of digestion solution is pH adjusted between 7.5 and 8.5 pH units using 5 M nitric acid. The pH adjusted solution is used in the preparation of the calibration curve for samples analyzed by method SW-846 7199.

4. 5.0 M nitric acid, analytical reagent grade - Purchased, or dilute 320 mL of concentrated nitric acid with reagent water to 1 L in a volumetric flask. See label for expiration date. Do not use concentrated nitric acid to prepare 5.0 M solution if it has a yellow tinge. Store at 20° to 25°C in the dark. Use a fresh portion from stock each time analysis is run.

5. Sulfuric acid, 10% (v/v) – Add 10 mL of concentrated sulfuric acid to approximately 70 mL of reagent water. Mix well and let cool. Dilute to 100 mL with reagent water. Solution expires 1 year from date of preparation. Store at room temperature in a glass container.
6. Potassium dichromate stock solution (50 mg/L Cr⁺⁶) – In a 1-L glass volumetric, dissolve 0.1414 ± .0001 g K₂Cr₂O₇ (dried for 4 hours at 105° ± 2°C) in reagent water and dilute to 1 L. This standard expires 6 months from date of preparation. Store at room temperature in a glass container.
7. Working chromium solution (5 mg/L Cr⁺⁶) – Dilute 10.0 mL of potassium dichromate stock solution to volume in a 100-mL volumetric flask with reagent water. Prepare fresh daily.

NOTE: A separate stock solution must be prepared using a different source for K₂Cr₂O₇. This second stock solution must be used for preparation of the calibration curve only.
8. 5.0 mg/kg LCS (Soluble LCS)/ICV/CCV – Pipette 2.5 mL of 5 mg/L hexavalent chromium working standard into approximately 2.5 g glass beads and add 50 mL of digest solution. Prepare fresh daily.

NOTE: For the Soluble LCS use 30 glass beads spiked with 2.5 mL of a 5 mg/L Working Standard solution. The weight assigned for each of these is 2.50 grams. The resulting concentration for the Soluble LCS is 5 mg/kg.
9. Lead chromate, PbCrO₄, analytical reagent grade. See label for expiration date. Store at room temperature.
10. LCS Insoluble Spike (LCSIS) - Add 10 to 20 mg of PbCrO₄ to approximately 2.5 g of glass beads

NOTE: Refer to Quality Assurance section for instructions for preparation of other quality control samples (Blank, PDS, SS, IS, and HSS)

11. Magnesium chloride, $MgCl_2$ (anhydrous), analytical reagent grade. Store at room temperature. See label for expiration date.
12. Phosphate buffer, 0.5M K_2HPO_4 /0.5M KH_2PO_4 – In a 1-L glass volumetric flask, dissolve $87.09 \pm .05$ g K_2HPO_4 and $68.04 \pm .05$ g KH_2PO_4 into approximately 700 mL of reagent water. Dilute to volume with reagent water. Solution expires 6 months from the date of preparation. Store solution at $4^\circ \pm 2^\circ C$.
13. Diphenylcarbazide solution – In a 50-mL volumetric flask, dissolve $250 \pm .5$ mg 1,5-diphenylcarbazide in 50 mL analytical reagent grade acetone. Store in an amber glass bottle at $4^\circ \pm 2^\circ C$. Solution expires 30 days from date of preparation. If solution becomes discolored before the expiration date, discard and prepare new.
14. Acetone – Reagent grade.
15. Glass beads – purchased; see container for shelf-life and storage information

Calibration:

1. 5.0 mg/kg ICV/CCV – Pipette 2.5 mL of 5 mg/L hexavalent chromium working standard into approximately 2.5 g of glass beads and add 50 mL of digest solution.

NOTE: For the Soluble LCS use 30 glass beads spiked with 2.5 mL of a 5 mg/L Working Standard solution. The weight assigned for each of these is 2.50 grams. The resulting concentration for the Soluble LCS is 5 mg/kg.

2. Follow the procedure instructions listed under sections B and C in the Procedure section for analysis of the 5.0 mg/kg ICV/CCV.

3. Every day that the analysis is performed, a 5 mg/kg ICV must be analyzed at the beginning of the run, followed immediately by a reagent blank. After every 10 samples and at the end of the run a CCV (5 mg/kg) followed by a reagent blank must be analyzed.
4. The acceptance range for the ICV/CCV is 80% to 120%.
5. See Procedure A. for preparation of calibration curve.

Procedure:

A. Preparation of calibration curve

1. Prepare a standard curve of seven standards and a reagent blank. Place volumes of 5.0 mg/L standard in 100-mL volumetric flasks and dilute to volume with reagent water. Use a separate source than that used for the LCS/LCSD. The lowest standard on the curve must be at or below the Limit of Quantitation (LOQ).

<u>Conc. (mg/L Cr⁺⁶)</u>	<u>mL of 5 mg/L Std.</u>
Reagent Blank	0
0.01	0.20
0.05	1.00
0.10	2.00
0.20	4.00
0.50	10.00
1.00	20.00
1.25	25.00

2. Use a graduated cylinder to transfer 45 mL of the standard to be tested to a 100-mL beaker.
3. Pipette 1.0 mL of diphenylcarbazide solution, add to the standard and mix well.

4. Add 10% sulfuric acid to each standard while stirring to adjust the pH to a range of 1.6 to 2.2. Test the pH of each standard with a calibrated pH meter when the effervescence has ceased, and record the final pH.
5. Add pH adjusted standard to a 50-mL volumetric flask and dilute to volume using reagent water, mix well. Let stand for 5 to 10 minutes for full color development.
6. Read the absorbance of the standards with a 1-cm cell at 540 nm, using reagent water to zero the spectrophotometer.

The concentrations of the samples are calculated from the eight points in this curve. This curve must be done every day the analysis is performed. The curve must have a correlation coefficient of $\geq .995$. If the correlation coefficient is $< .995$, a new calibration curve must be analyzed. The calibration curve calculator application in the LIMS determines the correlation coefficient.

B. Sample preparation and digestion

1. Place 2.5 ± 0.10 g of the as-received sample, a stir bar, and 50 mL of digestion solution (using a graduated cylinder) into a 250-mL beaker.
2. Add approximately 400 mg of $MgCl_2$ and 0.5 mL of the phosphate buffer.
3. Cover with a watch glass.
4. Stir the samples continuously (unheated) for at least 5 minutes using an appropriate stirring device.
5. Heat the sample and maintain a temperature range of 90° to $95^\circ C$ with constant stirring for 60 minutes. Do not allow sample to go to dryness; it is possible for hexavalent chromium to be lost due to side reactions in the sample matrix.

6. The temperature during digestion must be recorded at the 30 minute and 60 minute interval of digestion.
7. After the digest has cooled to room temperature, filter it quantitatively through a 0.45- μ m filter.
8. Rinse the filtering apparatus with reagent water and transfer the filtrate and the rinses to a clean 250-mL beaker.
9. **Slowly, and with constant stirring, add 5.0 M nitric acid to the beaker dropwise.** For samples to be analyzed by SW-846 7196A, adjust the pH of the solution to 7.5 ± 0.5 while monitoring the pH with a pH meter.
10. Record the pH in the data book.
11. If the pH of the solution drops below 7.0, discard the solution and redigest. If overshooting of the pH 7.5 ± 0.5 occurs repeatedly, prepare a diluted nitric acid solution and repeat the digestion procedure.
12. If a flocculent precipitate forms, the sample must be filtered through a 0.45- μ m membrane filter. If the filter becomes clogged using the 0.45- μ m filter paper, a larger size filter paper (Whatman GFB or GFF) is used to prefilter the samples.

CAUTION: Carbon dioxide is evolved during this step.

NOTE: When the digest is to be analyzed by SW-846 7199, adjust the pH of the solution to 9.0 ± 0.5 while monitoring the pH with a pH meter. If the pH of the solution drops below 8.5, discard the solution and redigest. If overshooting of the pH 9.0 ± 0.5 occurs repeatedly, prepare a diluted nitric acid solution and repeat the digestion procedure.

13. Quantitatively transfer the contents of the beaker to a 100-mL volumetric flask and dilute to volume with reagent water. Mix well.

14. The extracts are now ready for analysis by SW-846 7196A or SW-846 7199.
15. When samples are digested for analysis by SW-846 7196A, enter the digests under analysis 7825. When samples are digested for analysis by SW-846 7199, enter the digests under analysis 2432.

C. Color development and measurement

1. For all samples (field samples and QC samples) quantitatively transfer 45.0 mL of the sample to a 100-mL beaker.
2. Add 1.0 mL of diphenylcarbazide solution and mix well.
3. Add 10% sulfuric acid to each sample and mix well after each addition to adjust the pH to a range of 1.5 to 2.5.
4. Test the pH of each sample with a pH meter when the effervescence has ceased (up to about 10 minutes) and record the final reading in the laboratory notebook.
5. Carefully pour the sample into a 50-mL volumetric flask, dilute the sample to a final volume of 50 mL using reagent water, mix well, and let stand 5 to 10 minutes for full color development.
6. Take a reading of the sample on the instrument being used.
7. All samples require a sample blank.
 - a. Take approximately 10 mL of the original sample (without adding the diphenylcarbazide) to use for background correction.
 - b. Add sulfuric acid and mix well after each addition until the pH is adjusted to a range of 1.5 to 2.5.

- c. Test the pH of each sample with a pH meter when the effervescence has ceased (up to about 10 minutes) and record the final reading in the laboratory notebook.
 - d. Do not add diphenylcarbazine.
8. Set the spectrophotometer at 540 nm by pressing "540, Go to WL."
 9. Zero the spectrophotometer by pouring reagent water into the 1-cm cell and placing it in the first position. Press "Auto Zero."
 10. Using the 1-cm cell and the spectrophotometer at 540 nm, read the absorbance of the samples starting with the reagent blank.
 - a. Use a Kimwipe to remove any fingerprints or moisture on the cell.
 - b. There must be no air bubbles in the cell.
 - c. In between samples, rinse the cell with reagent water.
 11. Dilute the samples if they are more concentrated than the highest standard on the curve.

Calculations:

$$\text{mg/kgCr}^{+6} = \left(\frac{CV}{W} \right) \times DF$$

Where:

- C = mg/L Cr⁺⁶ in digestate
V = Volume of digestate in milliliters
W = Sample weight digested in grams
DF = Dilution factor

Relative Percent Difference:

$$RPD = (S - D) / [(S + D) / 2] \times 100$$

Where:

S = Initial sample result

D = Duplicate sample result

Spike added:*Insoluble/Insoluble spike duplicate added = (mg of $PbCrO_4$ x 0.1608)/Kg of sample***Where:**0.1608 is the fraction of Cr in $PbCrO_4$: $(51.996g/323.4g) = 0.1608$ **Spike Recovery:**

$$Percent Recovery = [(SSR - SR) / SA] \times 100$$

Where:

SSR = Spike sample result

SR = Sample (unspiked) result

SA = Spike added

When clients request results on a dry-weight basis, the samples are analyzed for moisture content and a dry-weight report is generated.

Statistical Information/Method Performance:

Statistical windows are performed twice a year and MDLs are performed on an annual basis. MDLs and LOQs are determined according to LOM-SOP-ES-203. Initial Demonstration of Capabilities are documented in analysts training records.

Quality Assurance/Quality Control:

All quality control samples are digested under the same conditions as client samples.

NOTE: For the Blank use 30 glass beads, and for the Soluble LCS use 30 glass beads spiked with 2.5 mL of a 5 mg/L Working Standard solution. The weight assigned for each of these is 2.50 grams. The resulting concentration for the Soluble LCS is 5 mg/kg.

One blank (prepared by adding approximately 2.5 g of glass beads to 50 mL of digest solution – see NOTE above) and two duplicates must be run with every batch (not more than 20 samples). The acceptable relative percent difference (RPD) for duplicates must be less than or equal to 20%. A blank is acceptable when its result is less than the existing Limit of Quantitation (LOQ). The run sequence is as follows: ICV, blank, LCSIS, 10 samples, CCV, blank, 10 samples, CCV, blank. This run sequence is repeated until the batch contains no more than 20 samples. Every day that the analysis is performed, a 5 mg/kg LCS/ICV must be analyzed at the beginning of the run, followed immediately by a reagent blank. After every 10 samples and at the end of the run a CCV (5 mg/kg) followed by a reagent blank must be analyzed. The acceptance range for the LCS/CCV is 80% to 120%. A LCS Insoluble Spike (LCSIS) of approximately 900 mg/kg must be analyzed per batch. The acceptance range for the LCSIS is 75% to 125%.

NOTE: The 5 mg/kg LCS/ICV/CCV and the LCSIS preparation are documented in the reagent and standards section.

Both soluble and insoluble predigestion matrix spikes must be analyzed per batch (not more than 20 samples). The soluble matrix spike (SS) is spiked with 2.0 mL of stock standard (equivalent to 40 mg/kg Cr⁺⁶) or at twice the sample concentration, whichever is greater. The insoluble matrix spike (IS) is prepared by adding 10 to 20 mg of PbCrO₄ to a separate sample aliquot. The matrix spike is then carried through the digestion

process. The acceptance range for the SS and IS is 75% to 125%. If any of the matrix spike recoveries are not within the quality control limits (see below), the entire batch must be redigested/reanalyzed. If upon reanalysis any of the matrix spikes are not within the quality control limits, but the LCS is within quality control specifications, the Cr⁺⁶ data is acceptable. Refer to SOP-WQ-017 for acceptance criteria.

A post-digestion matrix spike (PDS) must be analyzed per batch (not more than 20 samples). This spike must be equivalent to 40 mg/kg or twice the sample concentration, whichever is greater. The acceptance range for the PDS is 85% to 115% recovery.

NOTE: Do not spike the PDS until after the analysis of the original sample. Use the same sample for the PDS as was used for the pre-spike. If the post-digestion matrix spike is not within quality control limits, the entire batch must be redigested/reanalyzed.

NOTE: For Account #07079 and Account #06101 an Insoluble Spike Duplicate (ISD) is required instead of a LCSIS. Also, for Account # 07079 a High Level Soluble Spike (HSS) must be analyzed per batch. The concentration of the HSS is 400 mg/kg. The acceptance window for this spike is 75% to 125%. For this account (#07079), if any matrix spike recoveries on the batch are not within the control limits the batch **must not** be redigested or reanalyzed without the client's direction.

Samples from the State of NJ must also be analyzed for pH (analysis 0394) and ORP (Analysis #1821).

NOTE: For account # 10651, ORP and pH must first be analyzed on the same sample aliquot and evaluated against the ORP/PH curve so that samples are digested in separate oxidizing and reducing batches to be analyzed by SW 846-7199.

The Quality Control prescribed in each of the pH and ORP SOPs must be followed during the analysis and included in the data deliverables.

No. L-18

pH (solid)

USEPA Method 9045D

METHOD 9045D

SOIL AND WASTE pH

1.0 SCOPE AND APPLICATION

1.1 This method is an electrometric procedure for measuring pH in soils and waste samples. Wastes may be solids, sludges, or non-aqueous liquids. If water is present, it must constitute less than 20% of the total volume of the sample.

2.0 SUMMARY OF METHOD

2.1 The sample is mixed with reagent water, and the pH of the resulting aqueous solution is measured.

3.0 INTERFERENCES

3.1 Samples with very low or very high pH may give incorrect readings on the meter. For samples with a true pH of >10 , the measured pH may be incorrectly low. This error can be minimized by using a low-sodium-error electrode. Strong acid solutions, with a true pH of <1 , may give incorrectly high pH measurements.

3.2 Temperature fluctuations will cause measurement errors.

3.3 Errors will occur when the electrodes become coated. If an electrode becomes coated with an oily material that will not rinse free, the electrode can (1) be cleaned with an ultrasonic bath, or (2) be washed with detergent, rinsed several times with water, placed in 1:10 HCl so that the lower third of the electrode is submerged, and then thoroughly rinsed with water, or (3) be cleaned per the manufacturer's instructions.

4.0 APPARATUS AND MATERIALS

4.1 pH meter with means for temperature compensation.

4.2 Glass electrode.

4.3 Reference electrode -- A silver-silver chloride or other reference electrode of constant potential may be used.

NOTE: Combination electrodes incorporating both measuring and referenced functions are convenient to use and are available with solid, gel-type filling materials that require minimal maintenance.

4.4 Beaker -- 50-mL.

4.5 Thermometer and/or temperature sensor for automatic compensation.

4.6 Analytical balance -- capable of weighing 0.1 g.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Primary standard buffer salts are available from the National Institute of Standards and Technology (NIST) and should be used in situations where extreme accuracy is necessary. Preparation of reference solutions from these salts requires some special precautions and handling, such as low-conductivity dilution water, drying ovens, and carbon-dioxide-free purge gas. These solutions should be replaced at least once each month.

5.4 Secondary standard buffers may be prepared from NIST salts or purchased as solutions from commercial vendors. These commercially available solutions, which have been validated by comparison with NIST standards, are recommended for routine use.

6.0 SAMPLE PRESERVATION AND HANDLING

Samples should be analyzed as soon as possible.

7.0 PROCEDURE

7.1 Calibration

7.1.1 Because of the wide variety of pH meters and accessories, detailed operating procedures cannot be incorporated into this method. Each analyst must be acquainted with the operation of each system and familiar with all instrument functions. Special attention to care of the electrodes is recommended.

7.1.2 Each instrument/electrode system must be calibrated at a minimum of two points that bracket the expected pH of the samples and are approximately three pH units or more apart. Repeat adjustments on successive portions of the two buffer solutions until readings are within 0.05 pH units of the buffer solution value. If an accurate pH reading based on the conventional pH scale [0 to 14 at 25 EC] is required, the analyst should control sample temperature at 25 ± 1 EC when sample pH approaches the alkaline end of the scale (e.g., a pH of 11 or above).

7.2 Sample preparation and pH measurement of soils:

7.2.1 To 20 g of soil in a 50-mL beaker, add 20 mL of reagent water, cover, and continuously stir the suspension for 5 min. Additional dilutions are allowed if working with hygroscopic soils and salts or other problematic matrices.

7.2.2 Let the soil suspension stand for about 1 hr to allow most of the suspended clay to settle out from the suspension or filter or centrifuge off the aqueous phase for pH measurement.

7.2.3 Adjust the electrodes in the clamps of the electrode holder so that, upon lowering the electrodes into the beaker, the glass electrode will be immersed just deep enough into the clear supernatant solution to establish a good electrical contact through the ground-glass joint or the fiber-capillary hole. Insert the electrodes into the sample solution in this manner. For combination electrodes, immerse just below the suspension.

7.2.4 If the sample temperature differs by more than 2 °C from the buffer solution, the measured pH values must be corrected.

7.2.5 Report the results as "soil pH measured in water at __°C" where "__°C" is the temperature at which the test was conducted.

7.3 Sample preparation and pH measurement of waste materials

7.3.1 To 20 g of waste sample in a 50-mL beaker, add 20 mL of reagent water, cover, and continuously stir the suspension for 5 min. Additional dilutions are allowed if working with hygroscopic wastes and salts or other problematic matrices.

7.3.2 Let the waste suspension stand for about 15 min to allow most of the suspended waste to settle out from the suspension or filter or centrifuge off aqueous phase for pH measurement.

NOTE: If the waste is hygroscopic and absorbs all the reagent water, begin the experiment again using 20 g of waste and 40 mL of reagent water.

NOTE: If the supernatant is multiphasic, decant the oily phase and measure the pH of the aqueous phase. The electrode may need to be cleaned (Step 3.3) if it becomes coated with an oily material.

7.3.3 Adjust the electrodes in the clamps of the electrode holder so that, upon lowering the electrodes into the beaker, the glass electrode will be immersed just deep enough into the clear supernatant to establish good electrical contact through the ground-glass joint or the fiber-capillary hole. Insert the electrode into the sample solution in this manner. For combination electrodes, immerse just below the suspension.

7.3.4 If the sample temperature differs by more than 2 °C from the buffer solution, the measured pH values must be corrected.

7.3.5 Report the results as "waste pH measured in water at __°C" where "__°C" is the temperature at which the test was conducted.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One for the appropriate QC protocols.

8.2 Electrodes must be thoroughly rinsed between samples.

9.0 METHOD PERFORMANCE

9.1 No data provided.

METHOD 9045D
SOIL AND WASTE pH

No. L-19

pH (liquid)

USEPA Method 9040C

METHOD 9040C

pH ELECTROMETRIC MEASUREMENT

1.0 SCOPE AND APPLICATION

1.1 This method is used to measure the pH of aqueous wastes and those multiphase wastes where the aqueous phase constitutes at least 20% of the total volume of the waste.

1.2 The corrosivity of concentrated acids and bases, or of concentrated acids and bases mixed with inert substances, cannot be measured. The pH measurement requires some water content.

2.0 SUMMARY

2.1 The pH of the sample is determined electrometrically using either a glass electrode in combination with a reference potential or a combination electrode. The measuring device is calibrated using a series of standard solutions of known pH.

3.0 INTERFERENCES

3.1 The glass electrode, in general, is not subject to solution interferences from color, turbidity, colloidal matter, oxidants, reductants, or moderate (<0.1 molar solution) salinity.

3.2 Sodium error at pH levels >10 can be reduced or eliminated by using a low-sodium-error electrode.

3.3 Coatings of oily material or particulate matter can impair electrode response. These coatings can usually be removed by gentle wiping or detergent washing, followed by rinsing with distilled water. An additional treatment with hydrochloric acid (1:10) may be necessary to remove any remaining film.

3.4 Temperature effects on the electrometric determination of pH arise from two sources. The first is caused by the change in electrode output at various temperatures. This interference should be controlled with instruments having temperature compensation or by calibrating the electrode-instrument system at the temperature of the samples. The second source of temperature effects is the change of pH due to changes in the sample as the temperature changes. This error is sample-dependent and cannot be controlled. It should, therefore, be noted by reporting both the pH and temperature at the time of analysis.

4.0 APPARATUS AND MATERIALS

4.1 pH meter -- Laboratory or field model. Many instruments are commercially available with various specifications and optional equipment.

4.2 Glass electrode.

4.3 Reference electrode -- A silver-silver chloride or other reference electrode of constant potential may be used.

NOTE: Combination electrodes incorporating both measuring and referenced functions are convenient to use and are available with solid, gel-type filling materials that require minimal maintenance.

4.4 Magnetic stirrer and Teflon-coated stirring bar.

4.5 Thermometer and/or temperature sensor for automatic compensation.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Primary standard buffer salts are available from the National Institute of Standards and Technology (NIST) and should be used in situations where extreme accuracy is necessary. Preparation of reference solutions from these salts requires some special precautions and handling, such as low-conductivity dilution water, drying ovens, and carbon-dioxide-free purge gas. These solutions should be replaced at least once each month.

5.3 Secondary standard buffers may be prepared from NIST salts or purchased as solutions from commercial vendors. These commercially available solutions have been validated by comparison with NIST standards and are recommended for routine use.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

Samples should be analyzed as soon as possible.

7.0 PROCEDURE

7.1 Calibration

7.1.1 Because of the wide variety of pH meters and accessories, detailed operating procedures cannot be incorporated into this method. Each analyst must be acquainted with the operation of each system and familiar with all instrument functions. Special attention to care of the electrodes is recommended.

7.1.2 Each instrument/electrode system must be calibrated at a minimum of two points that bracket the expected pH of the samples and are approximately three pH units or more apart. (For corrosivity characterization, the calibration of the pH meter should include a buffer of pH 2 for acidic wastes and a pH 12 buffer for caustic wastes; also, for corrosivity characterization, the sample must be measured at 25 ± 1 EC if the pH of the waste is above 12.0.) Various instrument designs may involve use of a dial (to "balance" or "standardize") or a slope adjustment, as outlined in the manufacturer's instructions. Repeat adjustments on successive portions of the two buffer solutions until readings are within 0.05 pH units of the buffer solution value.

7.2 Place the sample or buffer solution in a clean glass beaker using a sufficient volume to cover the sensing elements of the electrodes and to give adequate clearance for the

magnetic stirring bar. If field measurements are being made, the electrodes may be immersed directly into the sample stream to an adequate depth and moved in a manner to ensure sufficient sample movement across the electrode-sensing element as indicated by drift-free readings (< 0.1 pH).

7.3 If the sample temperature differs by more than 2 °C from the buffer solution, the measured pH values must be corrected. Instruments are equipped with automatic or manual compensators that electronically adjust for temperature differences. Refer to manufacturer's instructions.

7.4 Thoroughly rinse and gently wipe the electrodes prior to measuring pH of samples. Immerse the electrodes into the sample beaker or sample stream and gently stir at a constant rate to provide homogeneity and suspension of solids. Note and record sample pH and temperature. Repeat measurement on successive aliquots of sample until values differ by < 0.1 pH units. Two or three volume changes are usually sufficient.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One for the appropriate QC protocols.

8.2 Electrodes must be thoroughly rinsed between samples.

9.0 METHOD PERFORMANCE

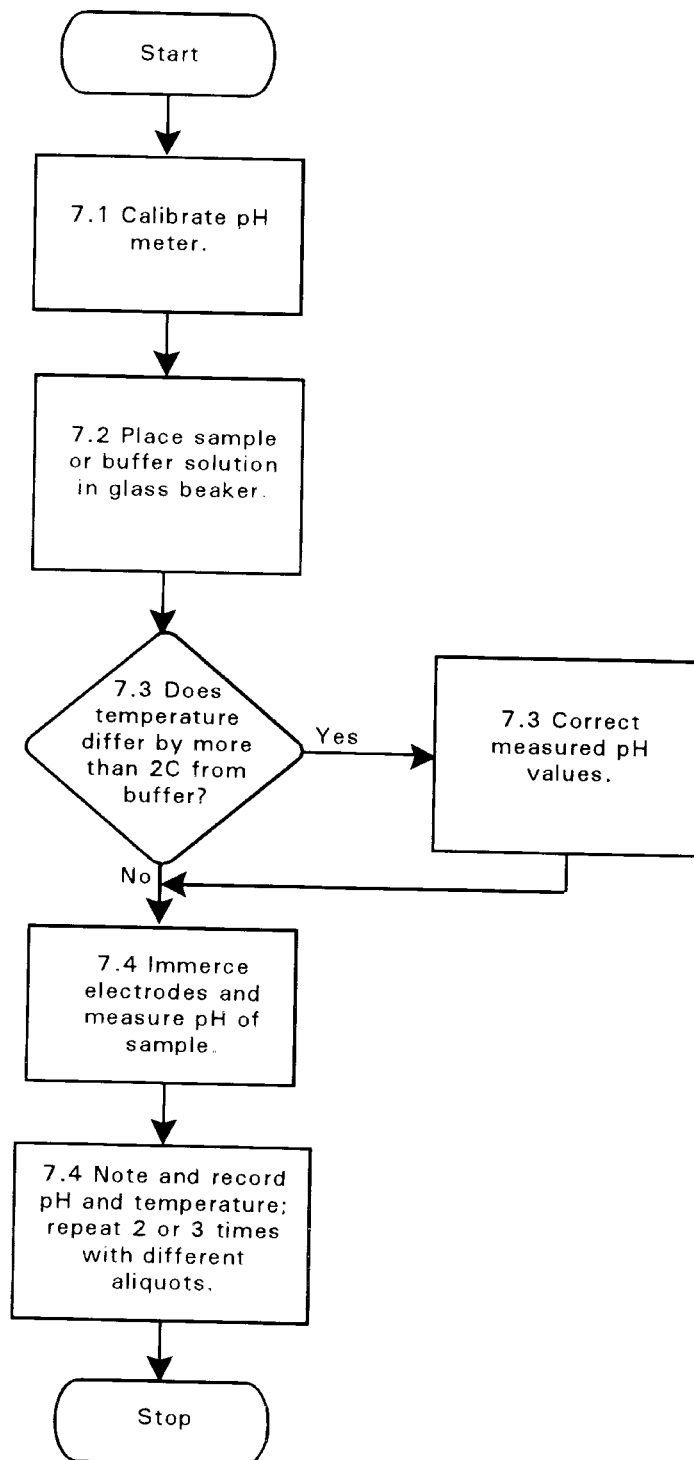

9.1 Forty-four analysts in twenty laboratories analyzed six synthetic water samples containing exact increments of hydrogen-hydroxyl ions, with the following results:

pH Units	Standard Deviation pH Units	Accuracy as	
		Bias %	Bias pH Units
3.5	0.10	-0.29	-0.01
3.5	0.11	-0.00	
7.1	0.20	+1.01	+0.07
7.2	0.18	-0.03	-0.002
8.0	0.13	-0.12	-0.01
8.0	0.12	+0.16	+0.01

No. L-20

% Moisture (solid)

ASTM D2216

Designation: D 2216 – 98

Standard Test Method for Laboratory Determination of Water (Moisture) Content of Soil and Rock by Mass¹

This standard is issued under the fixed designation D 2216; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope *

1.1 This test method covers the laboratory determination of the water (moisture) content by mass of soil, rock, and similar materials where the reduction in mass by drying is due to loss of water except as noted in 1.4, 1.5, and 1.7. For simplicity, the word “material” hereinafter also refers to either soil or rock, whichever is most applicable.

1.2 Some disciplines, such as soil science, need to determine water content on the basis of volume. Such determinations are beyond the scope of this test method.

1.3 The water content of a material is defined in 3.2.1.

1.4 The term “solid material” as used in geotechnical engineering is typically assumed to mean naturally occurring mineral particles of soil and rock that are not readily soluble in water. Therefore, the water content of materials containing extraneous matter (such as cement, and the like) may require special treatment or a qualified definition of water content. In addition, some organic materials may be decomposed by oven drying at the standard drying temperature for this method (110°C). Materials containing gypsum (calcium sulfate dihydrate or other compounds having significant amounts of hydrated water) may present a special problem as this material slowly dehydrates at the standard drying temperature (110°C) and at very low relative humidities, forming a compound (calcium sulfate hemihydrate) which is not normally present in natural materials except in some desert soils. In order to reduce the degree of dehydration of gypsum in those materials containing gypsum, or to reduce decomposition in highly organic soils, it may be desirable to dry these materials at 60°C or in a desiccator at room temperature. Thus, when a drying temperature is used which is different from the standard drying temperature as defined by this test method, the resulting water content may be different from standard water content determined at the standard drying temperature.

NOTE 1—Test Methods D 2974 provides an alternate procedure for determining water content of peat materials.

¹ This test method is under the jurisdiction of ASTM Committee D-18 on Soil and Rock and is the direct responsibility of Subcommittee D18.03 on Texture, Plasticity and Density Characteristics of Soils.

Current edition approved Feb. 10, 1998. Published January 1999. Originally published as D 2216 – 63 T. Last previous edition D 2216 – 92.

1.5 Materials containing water with substantial amounts of soluble solids (such as salt in the case of marine sediments) when tested by this method will give a mass of solids which includes the previously soluble solids. These materials require special treatment to remove or account for the presence of precipitated solids in the dry mass of the specimen, or a qualified definition of water content must be used. For example, see Noorany² regarding information on marine soils.

1.6 This test method requires several hours for proper drying of the water content specimen. Test Method D 4643 provides for drying of the test specimen in a microwave oven which is a shorter process. Also see Gilbert³ for details on the background of this test method.

1.7 This standard requires the drying of material in an oven at high temperatures. If the material being dried is contaminated with certain chemicals, health and safety hazards can exist. Therefore, this standard should not be used in determining the water content of contaminated soils unless adequate health and safety precautions are taken.

1.8 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 Refer to Terminology D 653 for standard definitions of terms.

3.2 Definitions of Terms Specific to This Standard:

3.2.1 *water content (of a material)*—the ratio expressed as a percent of the mass of “pore” or “free” water in a given mass of material to the mass of the solid material. A standard temperature of $110^{\circ} \pm 5^{\circ}\text{C}$ is used to determine these masses.

4. Summary of Test Method

4.1 A test specimen is dried in an oven at a temperature of $110^{\circ} \pm 5^{\circ}\text{C}$ to a constant mass. The loss of mass due to drying is considered to be water. The water content is calculated using the mass of water and the mass of the dry specimen.

5. Significance and Use

5.1 For many materials, the water content is one of the most significant index properties used in establishing a correlation between soil behavior and its index properties.

5.2 The water content of a material is used in expressing the phase relationships of air, water, and solids in a given volume of material.

5.3 In fine-grained (cohesive) soils, the consistency of a given soil type depends on its water content. The water content of a soil, along with its liquid and plastic limits as determined by Test Method D 4318, is used to express its relative consistency or liquidity index.

6. Apparatus

6.1 *Drying Oven*, thermostatically-controlled, preferably of the forced-draft type, meeting the requirements of Specification E 145 and capable of maintaining a uniform temperature of $110 \pm 5^{\circ}\text{C}$ throughout the drying chamber.

6.2 *Balances*—All balances must meet the requirements of Specification D 4753 and this section. A Class GP1 balance of 0.01g readability is required for specimens having a mass of up to 200 g (excluding mass of specimen container) and a Class GP2 balance of 0.1g readability is required for specimens having a mass over 200 g. However, the balance used may be controlled by the number of significant digits needed (see 8.2.1 and 12.1.2).

6.3 *Specimen Containers*—Suitable containers made of material resistant to corrosion and change in mass upon repeated heating, cooling, exposure to materials of varying pH, and cleaning. Unless a desiccator is used, containers with close-fitting lids shall be used for testing specimens having a mass of

less than about 200 g; while for specimens having a mass greater than about 200 g, containers without lids may be used (see Note 7). One container is needed for each water content determination.

NOTE 2—The purpose of close-fitting lids is to prevent loss of moisture from specimens before initial mass determination and to prevent absorption of moisture from the atmosphere following drying and before final mass determination.

6.4 *Desiccator*—A desiccator cabinet or large desiccator jar of suitable size containing silica gel or anhydrous calcium sulfate. It is preferable to use a desiccant which changes color to indicate it needs reconstitution. See 10.5.

NOTE 3—Anhydrous calcium sulfate is sold under the trade name Drierite.

6.5 *Container Handling Apparatus*, gloves, tongs, or suitable holder for moving and handling hot containers after drying.

6.6 *Miscellaneous*, knives, spatulas, scoops, quartering cloth, sample splitters, etc, as required.

7. Samples

7.1 Samples shall be preserved and transported in accordance with Practice 4220 Groups B, C, or D soils. Keep the samples that are stored prior to testing in noncorrodible airtight containers at a temperature between approximately 3 and 30°C and in an area that prevents direct contact with sunlight. Disturbed samples in jars or other containers shall be stored in such a way as to prevent or minimize moisture condensation on the insides of the containers.

7.2 The water content determination should be done as soon as practicable after sampling, especially if potentially corrodible containers (such as thin-walled steel tubes, paint cans, etc.) or plastic sample bags are used.

8. Test Specimen

8.1 For water contents being determined in conjunction with another ASTM method, the specimen mass requirement stated in that method shall be used if one is provided. If no minimum specimen mass is provided in that method then the values given below shall apply. See Howard⁷ for background data for the values listed.

8.2 The minimum mass of moist material selected to be representative of the total sample shall be in accordance with the following:

Maximum particle size (100 % passing)	Standard Sieve Size	Recommended minimum mass of moist test specimen for water content reported to $\pm 0.1\%$	Recommended minimum mass of moist test specimen for water content reported to $\pm 1\%$
2 mm or less	No. 10	20 g	20 g ^A
4.75 mm	No. 4	100 g	20 g ^A
9.5 mm	3/8-in.	500 g	50 g
19.0 mm	3/4-in.	2.5 kg	250 g
37.5 mm	1 1/2 in.	10 kg	1 kg

⁷ Howard, A. K., “Minimum Test Specimen Mass for Moisture Content Determination”, *Geotechnical Testing Journal*, A.S.T.M., Vol. 12, No. 1, March 1989, pp. 39-44.

⁵ *Annual Book of ASTM Standards*, Vol 04.09.

⁶ *Annual Book of ASTM Standards*, Vol 14.02.

75.0 mm

3-in.

50 kg

5 kg

^ATo be representative not less than 20 g shall be used.

8.2.1 The minimum mass used may have to be increased to obtain the needed significant digits for the mass of water when reporting water contents to the nearest 0.1 % or as indicated in 12.1.2.

8.3 Using a test specimen smaller than the minimum indicated in 8.2 requires discretion, though it may be adequate for the purposes of the test. Any specimen used not meeting these requirements shall be noted on the test data forms or test data sheets.

8.4 When working with a small (less than 200g) specimen containing a relatively large gravel particle, it is appropriate not to include this particle in the test specimen. However, any discarded material shall be described and noted on the test data forms or test data sheets.

8.5 For those samples consisting entirely of intact rock, the minimum specimen mass shall be 500 g. Representative portions of the sample may be broken into smaller particles, depending on the sample's size, the container and balance being used and to facilitate drying to constant mass, see 10.4. Specimen sizes as small as 200 g may be tested if water contents of only two significant digits are acceptable.

9. Test Specimen Selection

9.1 When the test specimen is a portion of a larger amount of material, the specimen must be selected to be representative of the water condition of the entire amount of material. The manner in which the test specimen is selected depends on the purpose and application of the test, type of material being tested, the water condition, and the type of sample (from another test, bag, block, and the likes.)

9.2 For disturbed samples such as trimmings, bag samples, and the like, obtain the test specimen by one of the following methods (listed in order of preference):

9.2.1 If the material is such that it can be manipulated and handled without significant moisture loss and segregation, the material should be mixed thoroughly and then select a representative portion using a scoop of a size that no more than a few scoops are required to obtain the proper size of specimen defined in 8.2.

9.2.2 If the material is such that it cannot be thoroughly mixed or mixed and sampled by a scoop, form a stockpile of the material, mixing as much as possible. Take at least five portions of material at random locations using a sampling tube, shovel, scoop, trowel, or similar device appropriate to the maximum particle size present in the material. Combine all the portions for the test specimen.

9.2.3 If the material or conditions are such that a stockpile cannot be formed, take as many portions of the material as practical, using random locations that will best represent the moisture condition. Combine all the portions for the test specimen.

9.3 Intact samples such as block, tube, split barrel, and the like, obtain the test specimen by one of the following methods depending on the purpose and potential use of the sample.

9.3.1 Using a knife, wire saw, or other sharp cutting device, trim the outside portion of the sample a sufficient distance to see if the material is layered and to remove material that

appears more dry or more wet than the main portion of the sample. If the existence of layering is questionable, slice the sample in half. If the material is layered, see 9.3.3.

9.3.2 If the material is not layered, obtain the specimen meeting the mass requirements in 8.2 by: (1) taking all or one-half of the interval being tested; (2) trimming a representative slice from the interval being tested; or (3) trimming the exposed surface of one-half or from the interval being tested.

NOTE 4—Migration of moisture in some cohesionless soils may require that the full section be sampled.

9.3.3 If a layered material (or more than one material type is encountered), select an average specimen, or individual specimens, or both. Specimens must be properly identified as to location, or what they represent, and appropriate remarks entered on the test data forms or test data sheets.

10. Procedure

10.1 Determine and record the mass of the clean and dry specimen container (and its lid, if used).

10.2 Select representative test specimens in accordance with Section 9.

10.3 Place the moist test specimen in the container and, if used, set the lid securely in position. Determine the mass of the container and moist material using a balance (see 6.2) selected on the basis of the specimen mass. Record this value.

NOTE 5—To prevent mixing of specimens and yielding of incorrect results, all containers, and lids if used, should be numbered and the container numbers shall be recorded on the laboratory data sheets. The lid numbers should match the container numbers to eliminate confusion.

NOTE 6—To assist in the oven-drying of large test specimens, they should be placed in containers having a large surface area (such as pans) and the material broken up into smaller aggregations.

10.4 Remove the lid (if used) and place the container with moist material in the drying oven. Dry the material to a constant mass. Maintain the drying oven at $110 \pm 5^\circ\text{C}$ unless otherwise specified (see 1.4). The time required to obtain constant mass will vary depending on the type of material, size of specimen, oven type and capacity, and other factors. The influence of these factors generally can be established by good judgment, and experience with the materials being tested and the apparatus being used.

NOTE 7—In most cases, drying a test specimen overnight (about 12 to 16 h) is sufficient. In cases where there is doubt concerning the adequacy of drying, drying should be continued until the change in mass after two successive periods (greater than 1 h) of drying is an insignificant amount (less than about 0.1 %). Specimens of sand may often be dried to constant mass in a period of about 4 h, when a forced-draft oven is used.

NOTE 8—Since some dry materials may absorb moisture from moist specimens, dried specimens should be removed before placing moist specimens in the same oven. However, this would not be applicable if the previously dried specimens will remain in the drying oven for an additional time period of about 16 h.

10.5 After the material has dried to constant mass remove the container from the oven (and replace the lid if used). Allow the material and container to cool to room temperature or until the container can be handled comfortably with bare hands and the operation of the balance will not be affected by convection currents and/or its being heated. Determine the mass of the container and oven-dried material using the same type/capacity

balance used in 10.3. Record this value. Tight fitting lids shall be used if it appears that the specimen is absorbing moisture from the air prior to determination of its dry mass.

NOTE 9—Cooling in a desiccator is acceptable in place of tight fitting lids since it greatly reduces absorption of moisture from the atmosphere during cooling especially for containers without tight fitting lids.

11. Calculation

11.1 Calculate the water content of the material as follows:

$$w = [(M_{cws} - M_{cs}) / (M_{cs} - M_c)] \times 100 = \frac{M_w}{M_s} \times 100 \quad (1)$$

where:

- w = water content, %,
- M_{cws} = mass of container and wet specimen, g,
- M_{cs} = mass of container and oven dry specimen, g,
- M_c = mass of container, g,
- M_w = mass of water ($M_w = M_{cws} - M_{cds}$), g, and
- M_s = mass of solid particles ($M_s = M_{cds} - M_c$), g.

12. Report

12.1 Test data forms or test data sheets shall include the following:

12.1.1 Identification of the sample (material) being tested, such as boring number, sample number, test number, container number etc.

12.1.2 Water content of the specimen to the nearest 1 % or 0.1 %, as appropriate based on the minimum sample used. If this method is used in concert with another method, the water content of the specimen should be reported to the value required by the test method for which the water content is being determined. Refer to Guide D 6026 for guidance concerning significant digits, especially if the value obtained from this test method is to be used to calculate other relationships such as unit weight or density. For instance, if it is desired to express dry unit weight to the nearest 0.1 lbf/ft³ (0.02 kN/m³), it may be necessary to use a balance with a greater readability or use a larger specimen mass to obtain the required significant digits the mass of water so that the water content can be determined to the required significant digits. Also, the significant digits in Guide D 6026 may need to be increased when calculating phase relationships requiring four significant digits.

12.1.3 Indicate if test specimen had a mass less than the minimum indicated in 8.2.

12.1.4 Indicate if test specimen contained more than one material type (layered, etc.).

12.1.5 Indicate the temperature of drying if different from 110 ± 5°C.

12.1.6 Indicate if any material (size and amount) was excluded from the test specimen.

12.2 When reporting water content in tables, figures, etc., any data not meeting the requirements of this test method shall be noted, such as not meeting the mass, balance, or temperature requirements or a portion of the material is excluded from the test specimen.

13. Precision and Bias

13.1 *Statement on Bias*—There is no accepted reference value for this test method; therefore, bias cannot be determined.

13.2 *Statements on Precision*:

13.2.1 *Single-Operator Precision (Repeatability)*—The single-operator coefficient of variation has been found to be 2.7 percent. Therefore, results of two properly conducted tests by the same operator with the same equipment should not be considered suspect unless they differ by more than 7.8 percent of their mean.⁸

13.2.2 *Multilaboratory Precision (Reproducibility)*⁹—The multilaboratory coefficient of variation has been found to be 5.0 percent. Therefore, results of two properly conducted tests by different operators using different equipment should not be considered suspect unless they differ by more than 14.0 percent of their mean.

14. Keywords

14.1 consistency; index property; laboratory; moisture analysis; moisture content; soil aggregate; water content

⁸ These numbers represent the (1s) and (d2s) limits as described in Practice C 670.

⁹ These numbers represent the (1s %) and (d2s %) limits as described in Practice C 670.

SUMMARY OF CHANGES

Committee D-18 has identified the location of selected changes to this standard since the last issue. (D 2216-92) that may impact the use of this standard.

- (1) Title was changed to emphasize that mass is the basis for the standard.
- (2) Section 1.1 was revised to clarify “similar materials”.
- (3) New 1.2 was added to explain a limitation in scope. The other sections were renumbered as appropriate.
- (4) An information reference was included in 1.5.
- (5) An information reference was included in 1.6

- (6) A new ASTM referenced document was included in 2.1.
- (7) New Footnotes 2, 3, and 5 were added and identified. Other footnotes were renumbered where necessary for sequential identification.
- (8) Information concerning balances was added in 6.2
- (9) Section 6.3 was revised to clarify the use of close-fitting lids, and a reference to Note 8 was added.

(10) In 6.4, “anhydrous calcium phosphate” was changed to “anhydrous calcium sulfate” to correct an error and to agree with Note 3.

(11) A typo in 8.1 was corrected from “before” to “below” and a footnoted reference was added for information.

(12) A portion of 8.2 was deleted for clarity.

(13) A new 8.2.1 was added to clarify minimum mass requirements.

(14) Sections 8.3, 8.4, 9.3.3, and 12.1 were changed to substitute “test data form/sheet” for “report”.

(15) Footnote seven was identified.

(16) Section 9.2.1 was revised to improve clarity and intent.

(17) The word “possible” was changed to “practical” in 9.2.3.

(18) Section 9.3.1 and 9.3.2 were revised to improve clarity and for practicality.

(19) A reference to Guide D 6026 was added in 12.1.2.

(20) Footnotes 8 and 9 were added to 13.2.1 and 13.2.2, respectively. These were inadvertently omitted from the 1992 version. These explanations provide clarity and information to the user.

(21) A Summary of Changes was added to reflect D-18’s policy.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Scope:

This method is for the determination of moisture in most solid and semisolid samples.

1. SM20 2540-G is the preferred method when performing the moisture procedure and is used as our default method.
2. EPA Method 160.3 is a modified water procedure only used when specifically requested by a client.

Revision: 13	Effective date: Nov 15, 2012Nov 15, 2012Nov 15, 2012	Page 3 of 9
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Moisture (Gravimetric)	Eurofins Document Reference: 1-P-QM-WI -9015065
---	-----------------------------------	---	--

3. Analysis 6111 is used for Client Account #11187 only. ASTM D 2216-98 is only used for analysis 6111.
4. Analysis 7611 is used for sieved samples only. All other samples are analyzed by analysis 0111.
5. Analysis 11624 is used for Client Account #13013 only. The procedure follows SM20 2540-G but has client specific QC criteria.
6. Analysis 12845 is used for Client Account #12528 only. The procedure follows EPA 160.3 but has specific QC and LCS requirements.

Basic Principles:

A measured amount of sample is placed in an empty tared pan and dried in an oven at 103° to 105°C. The decrease in weight of the sample, after drying, is calculated as the moisture content of the sample.

Reference Modifications:

The method has been modified by using purchased aluminum foil pans that are not preconditioned, as this step is unnecessary.

EPA Method 160.3 is a water method used to determine percent solids. The modification is that it is used on solids to determine percent moisture.

Method SM2540 G requires multiple weights to be taken until the change in weight from the previous weight is within 4% or 50 mg (whichever is less). The modification is based on a study that was performed which determined that a constant weight was achieved after the initial drying cycle and therefore multiple weights were not necessary.

Interferences:

The determination of moisture in solid and semisolid materials is subject to error due to loss of ammonium carbonate and volatile organic matter during drying.

Revision: 13	Effective date: Nov 15, 2012Nov 15, 2012Nov 15, 2012	Page 4 of 9
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Moisture (Gravimetric)	Eurofins Document Reference: 1-P-QM-WI -9015065
--	-----------------------------------	---	--

Non-representative, nonhomogeneous materials, such as stones, are excluded from the analysis if their inclusion is not desired in the final result.

Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local state laws and regulations.

See Chemical Hygiene Plan for general information regarding employee safety, waste management and pollution prevention.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC) which is maintained in the analyst's training records.

Initially, each technician performing the analysis must work with an experienced technician for a period of time until they can independently perform the analysis. Proficiency is measured through an Initial Demonstration of Capability (IDOC).

The IDOC and the DOC consists of four laboratory control samples (or alternatively, one blind sample for the DOC) that are carried through all steps of the analysis and meet the defined acceptance criteria for the LCS.

Sample Collection, Preservation, and Handling:

Samples for moisture analysis must be kept in an unpreserved container and refrigerated at 4° + 2°C. Samples must be analyzed within 14 days of collection.

Apparatus and Equipment:

1. Disposable aluminum foil pans, or equivalent

Revision: 13	Effective date: Nov 15, 2012Nov 15, 2012Nov 15, 2012	Page 5 of 9
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Moisture (Gravimetric)	Eurofins Document Reference: 1-P-QM-WI -9015065
---	-----------------------------------	---	--

2. Oven maintained at 103° to 105°C. Adjust as needed to stay in this range. Refer to 1-P-QM-PRO-9015413.
3. Analytical balance, or equivalent. Refer to 1-P-QM-QMA-9017363
4. Desiccators, or equivalent. Refer to 1-P-QM-PRO-9015414
5. The LLENS is computer program that integrates a PC with an analytical balance to collect data directly from the balance. It also organizes the data, performs calculations and transmits the final results to the central computer system. The LLENS system must be used for moisture analysis. Refer to 1-P-QM-PRO-9015520.

Reagents and Standards:

Alternate weights are acceptable but final concentrations must remain the same. Refer to 1-P-QM-QMA-9017328 for the proper labeling and documentation of reagent preparations.

Standard solution of 10.5% NaCl: Add 895 ± 0.5g reagent water to 105 ± 0.2g NaCl in a beaker and mix thoroughly. Store at 4° ± 2°C. This solution is used as prepared. Stable 6 months. (Concentration of solution is approximately 89.5% moisture.)

Calibration:

Refer to 1-P-QM-QMA-9017363 for calibration procedures for analytical balances.

Procedure:

1. Verify that the balance has been calibrated each day before use.
2. Set up the batch in LLENS.
3. Number (for identification) the purchased disposable aluminum foil pans before use.

Revision: 13	Effective date: Nov 15, 2012Nov 15, 2012Nov 15, 2012	Page 6 of 9
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Moisture (Gravimetric)	Eurofins Document Reference: 1-P-QM-WI -9015065
---	-----------------------------------	---	--

4. Place one aluminum foil pan on a zeroed balance. Record pan tare weight in LLENS.
5. With the aluminum foil pan remaining on the balance, again zero the balance.
6. Place 5 to 10 grams of well-mixed sample into the pan.
7. Record the weight of the sample in LLENS.
8. Record the date and time on the LLENS batch worksheet according to 1-P-QM-QMA-9017372, and then place the pans containing sample into the oven.
 - a. Dry at 103° to 105°C for 8 to 48 hours.
 - b. Oven temperatures are monitored and logged by the Andover System through the use of a stationary probe. These temperature logs are maintained and eventually archived by the Sample Support staff. Refer to 1-P-QM-QMA-9017316.
9. Record the date and time on the LLENS batch worksheet, and then remove the pans containing dried sample from the oven.
10. Cool in a desiccator for 1 hour.

NOTE: Check desiccant to verify that the indicator crystals are still blue and not pink.
11. Again, verify that the balance has been calibrated each day before use.
12. Use tongs to place the pan containing dried sample on a zeroed balance. Record weight of pan and dried sample in LLENS.

Revision: 13	Effective date: Nov 15, 2012Nov 15, 2012Nov 15, 2012	Page 7 of 9
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Moisture (Gravimetric)	Eurofins Document Reference: 1-P-QM-WI -9015065
--	-----------------------------------	---	--

Calculations:

$$\%moisture = \frac{A - B}{C} \times 100$$

Where:

- A = Weight of sample and container before drying (in grams)
- B = Weight of sample and container after drying (in grams)
- C = Weight of sample before drying (in grams)

Statistical Information/Method Performance:

Refer to 1-P-QM-QMA-9017309

Quality Assurance/Quality Control:

Calibration verification of the balances must be performed each day before use.

An 89.5 % LCS must be run on each batch. Batch size is limited to 20 samples or less.

When sample volume permits, a sample matrix duplicate must be run with each group of not more than ten samples unless a client specifies otherwise.

See LIMS for current quality control (QC) acceptance windows. Follow guidelines in 1-P-QM-PRO-9015519 for outlier QC data.

Comments:

1. The analysis report for 6111 must include a comment stating, "A 5 g aliquot was dried at 103°-105°C and calculated as %moisture."
2. When a client submits a designated sample for QC, the matrix spike (MS) sample is entered for scan 0118.

Revision: 13	Effective date: Nov 15, 2012Nov 15, 2012Nov 15, 2012	Page 8 of 9
COMPANY CONFIDENTIAL		

	Lancaster Laboratories	Document Title: Moisture (Gravimetric)	Eurofins Document Reference: 1-P-QM-WI -9015065
---	-----------------------------------	---	--

- a. This allows the LLENS program to upload the moisture value from the client-designated background sample; this moisture value is often needed in the calculations of other analyses.
 - b. A client-submitted continuation sample is also entered for scan 0118 for the same reason.
 - c. Scan 6118 is specific to moistures done for Client Account #11187 only.
 - d. Scan 7618 is specific to moistures done on sieved samples only.
 - e. Scan 11625 is specific to moistures done for Client Account #13013 only.
 - f. Scan 12846 is specific to moistures done for Client Account #12528 only.
 - g. All other accounts use scan 0118.
3. When a client submits a designated sample for QC, the matrix spike duplicate (MSD) sample is entered for scan 0118 and scan 0121. (Scan 0118 provides the result for the MS and scan 0121 for the sample matrix duplicate.)
- a. Scan 6121 is specific to moistures done for Client Account #11187 only.
 - b. Scan 7621 is specific to moistures done on sieved samples only.
 - c. Scan 11626 is specific to moistures done for Client Account #13013 only.
 - d. Scan 12847 is specific to moistures done for Client Account #12528 only.
 - e. All other accounts use scan 0121.

Total Sulfide

SW-846 Method 9030B/9034

METHOD 9030B

ACID-SOLUBLE AND ACID-INSOLUBLE SULFIDES: DISTILLATION

1.0 SCOPE AND APPLICATION

1.1 The distillation procedure described in this method is designed for the determination of sulfides in aqueous, solid waste materials, or effluents.

1.2 This method provides only a semi-quantitative determination of sulfide compounds considered "acid-insoluble" (e.g., CuS and SnS₂) in solid samples. Recovery has been shown to be 20 to 40% for CuS, one of the most stable and insoluble compounds, and 40 to 60% for SnS₂ which is slightly more soluble.

1.3 This method is not applicable to oil or multiphasic samples or samples not amenable to the distillation procedure which can be analyzed by Method 9031.

1.4 Method 9030 is suitable for measuring sulfide concentrations in samples which contain between 0.2 and 50 mg/kg of sulfide.

1.5 This method is not applicable for distilling reactive sulfide. Method 9034 or Method 9215 may be used to quantify the concentration of sulfide from the reactivity test. Refer to Chapter Seven, Section 7.3.4.1 for the determination of reactive sulfide.

1.6 This method measures total sulfide which is usually defined as the acid-soluble fraction of a waste. If, however, one has previous knowledge of the waste and is concerned about both soluble sulfides such as H₂S, and metal sulfides, such as CuS and SnS₂, then total sulfide is defined as the combination of both acid-soluble and acid-insoluble fractions. For wastes where only metal sulfides are suspected to be present, only the acid-insoluble fraction needs to be performed.

2.0 SUMMARY OF METHOD

2.1 For acid-soluble sulfide samples, separation of sulfide from the sample matrix is accomplished by the addition of sulfuric acid to the sample. The sample is heated to 70°C and the hydrogen sulfide (H₂S) which is formed is distilled under acidic conditions and carried by a nitrogen stream into zinc acetate gas scrubbing bottles where it is precipitated as zinc sulfide.

2.2 For acid-insoluble sulfide samples, separation of sulfide from the sample matrix is accomplished by suspending the sample in concentrated hydrochloric acid by vigorous agitation. Tin(II) chloride is present to prevent oxidation of sulfide to sulfur by the metal ion (as in copper(II)), by the matrix, or by dissolved oxygen in the reagents. The prepared sample is distilled under acidic conditions at 100°C under a stream of nitrogen. Hydrogen sulfide gas is released from the sample and collected in gas scrubbing bottles containing zinc(II) and a strong acetate buffer. Zinc sulfide precipitates.

2.3 The sulfide in the zinc sulfide precipitate is quantified titrimetrically by Method 9034 or by ion selective electrode, Method 9215.

3.0 INTERFERENCES

3.1 Aqueous samples must be taken with a minimum of aeration to avoid volatilization of sulfide or reaction with oxygen, which oxidizes sulfide to sulfur compounds that are not detected.

3.2 Reduced sulfur compounds, such as sulfite and hydrosulfite, decompose in acid, and may form sulfur dioxide. This gas may be carried over to the zinc acetate gas scrubbing bottles and subsequently react with the iodine in the determinative step to yielding false high values. The addition of formaldehyde into the zinc acetate gas scrubbing bottles removes this interference. Any sulfur dioxide entering the scrubber will form an addition compound with the formaldehyde which is unreactive towards the iodine in the acidified mixture. This method shows no sensitivity to sulfite or hydrosulfite at concentrations up to 10 mg/kg of the interferant.

3.3 Interferences for acid-insoluble sulfides have not been fully investigated. However, sodium sulfite and sodium thiosulfate are known to interfere in the procedure for soluble sulfides. Sulfur also interferes because it may be reduced to sulfide by tin(II) chloride in this procedure.

3.4 The iodometric method suffers interference from reducing substances that react with iodine, including thiosulfate, sulfite, and various organic compounds.

3.5 The insoluble method should not be used for the determination of soluble sulfides because it can reduce sulfur to sulfide, thus creating a positive interference.

4.0 APPARATUS AND MATERIALS

4.1 Gas evolution apparatus as shown in Figure 1.

4.1.1 Three neck flask - 500-mL, 24/40 standard taper joints.

4.1.2 Dropping funnel - 100-mL, 24/40 outlet joint.

4.1.3 Purge gas inlet tube - 24/40 joint, with coarse frit.

4.1.4 Purge gas outlet - 24/40 joint reduced to 1/4 in. tube.

4.1.5 Gas scrubbing bottles - 125-mL, with 1/4 in. o.d. inlet and outlet tubes. Impinger tube must be fritted.

4.1.6 Tubing - 1/4 in. o.d. polytetrafluoroethylene (PTFE) or polypropylene. Do not use rubber.

NOTE: When analyzing for acid-insoluble sulfides, the distillation apparatus is identical to that used in the distillation procedure for acid-soluble sulfides except that the tubing and unions downstream of the distillation flask must be all PTFE, polypropylene or other material resistant to gaseous HCl. The ground glass joints should be fitted with PTFE sleeves to prevent seizing and to prevent gas leaks. Pinch clamps should also be used on the joints to prevent leaks.

- 4.2 Hot plate stirrer.
- 4.3 pH meter.
- 4.4 Nitrogen regulator.
- 4.5 Flowmeter.
- 4.6 Top-loading balance - capable of weighing 0.1 g.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Zinc acetate solution for sample preservation (2N), $\text{Zn}(\text{CH}_3\text{COO})_2 \cdot 2\text{H}_2\text{O}$. Dissolve 220 g of zinc acetate dihydrate in 500 mL of reagent water.

5.4 Sodium hydroxide (1N), NaOH. Dissolve 40 g of NaOH in reagent water and dilute to 1 liter.

5.5 Formaldehyde (37% solution), CH_2O . This solution is commercially available.

5.6 Zinc acetate for the scrubber

5.6.1 For acid-soluble sulfides: Zinc acetate solution (approximately 0.5M). Dissolve about 110 g zinc acetate dihydrate in 200 mL of reagent water. Add 1 mL hydrochloric acid (concentrated), HCl, to prevent precipitation of zinc hydroxide. Dilute to 1 liter.

5.6.2 For acid-insoluble sulfides: Zinc acetate/sodium acetate buffer. Dissolve 100 g sodium acetate, $\text{NaC}_2\text{H}_3\text{O}_2$, and 11 g zinc acetate dihydrate in 800 mL of reagent water. Add 1 mL concentrated hydrochloric acid and dilute to 1 liter. The resulting pH should be 6.8.

5.7 Acid to acidify the sample

5.7.1 For acid-soluble sulfides: Sulfuric acid (concentrated), H_2SO_4 .

5.7.2 For acid-insoluble sulfides: Hydrochloric acid (9.8N), HCl. Place 200 mL of reagent water in a 1-liter beaker. Slowly add concentrated HCl to bring the total volume to 1 liter.

5.8 Nitrogen.

5.9 Tin(II) chloride, SnCl₂, granular.

5.10 Sodium hydroxide (6N), NaOH. Dissolve 240 g of sodium hydroxide in 1 liter of reagent water.

5.11 Hydrochloric acid (6N), HCl. Place 51 mL of reagent water in a 100 mL Class A volumetric flask. Slowly add concentrated HCl to bring the total volume to 100 mL.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 All samples must have been collected using a sampling plan that addresses the considerations discussed in Chapter Nine of this manual.

6.2 All aqueous samples and effluents must be preserved with zinc acetate and sodium hydroxide. Use four drops of 2N zinc acetate solution per 100 mL of sample. Adjust the pH to greater than 9 with 6N sodium hydroxide solution. Fill the sample bottle completely and stopper with a minimum of aeration. The treated sample is relatively stable and can be held for up to seven days. If high concentrations of sulfide are expected to be in the sample, continue adding zinc acetate until all the sulfide has precipitated. For solid samples, fill the surface of the solid with 2N zinc acetate until moistened. Samples must be cooled to 4°C and stored headspace free.

6.3 Sample Preparation

6.3.1 For an efficient distillation, the mixture in the distillation flask must be of such a consistency that the motion of the stirring bar is sufficient to keep the solids from settling. The mixture must be free of solid objects that could disrupt the stirring bar. Prepare the sample using one of the procedures in this section then proceed with the distillation step (Section 7.0).

6.3.2 If the sample is aqueous, shake the sample container to suspend any solids, then quickly decant the appropriate volume (up to 250 mL) of the sample to a graduated cylinder, weigh the cylinder, transfer to the distillation flask and reweigh the cylinder to the nearest milligram. Be sure that a representative aliquot is used, or use the entire sample.

6.3.3 If the sample is aqueous but contains soft clumps of solid, it may be possible to break the clumps and homogenize the sample by placing the sample container on a jar mill and tumble or roll the sample for a few hours. The slurry may then be aliquotted and weighed as above to the nearest milligram then diluted with reagent water up to a total volume of 250 mL to produce a mixture that is completely suspended by the stirring bar.

6.3.4 If the sample is primarily aqueous, but contains a large proportion of solid, the sample may be roughly separated by phase and the amount of each phase measured and weighed to the nearest milligram into the distillation flask in proportion to their abundance in the sample. Reagent water may be added up to a total volume of 250 mL.

As a guideline, no more than 25 g dry weight or 50 g of sludge can be adequately suspended in the apparatus.

6.3.5 If the sample contains solids which absorb water and swell, limit the sample size to 25 g dry weight. Otherwise, the solids will restrict the fluid motion and lower the recovery.

6.3.6 If the sample contains solid objects that cannot be reduced in size by tumbling, the solids must be broken manually. Clay-like solids should be cut with a spatula or scalpel in a crystallizing dish. If the solids can be reduced to a size that they can be suspended by the stirring bar, the solid and liquid can be proportionately weighed.

6.3.7 Non-porous harder objects, for example stones or pieces of metal, may be weighed and discarded. The percent weight of non-porous objects should be reported and should be used in the calculation of sulfide concentration if it has a significant effect on the reported result.

7.0 PROCEDURE

For acid-soluble sulfide samples, proceed to Sec. 7.1.

For acid-insoluble sulfide samples, proceed to Sec. 7.2.

7.1 Acid-Soluble Sulfide

7.1.1 In a preliminary experiment, determine the approximate amount of sulfuric acid required to adjust a measured amount of the sample to pH less than or equal to 1. The sample size should be chosen so that it contains between 0.2 and 50 mg of sulfide. Place a known amount of sample or sample slurry in a beaker. Add reagent water until the total volume is 200 mL. Stir the mixture and determine the pH. Slowly add sulfuric acid until the pH is less than or equal to 1. Discard this preliminary sample.

CAUTION: Toxic hydrogen sulfide may be generated from the acidified sample. This operation must be performed in the hood and the sample left in the hood until the sample has been made alkaline or the sulfide has been destroyed. From the amount of sulfuric acid required to acidify the sample and the mass or volume of the sample acidified, calculate the amount of acid required to acidify the sample to be placed in the distillation flask.

7.1.2 Prepare the gas evolution apparatus as shown in Figure 1 in a fume hood.

7.1.2.1 Prepare a hot water bath at 70°C by filling a crystallizing dish or other suitable container with water and place it on a hot plate stirrer. Place a thermometer in the bath and monitor the temperature to maintain the bath at 70°C.

7.1.2.2 Assemble the three neck 500-mL flask, fritted gas inlet tube, and exhaust tube. Use PTFE sleeves to seal the ground glass joints. Place a PTFE coated stirring bar into the flask.

7.1.2.3 Place into each gas scrubbing bottle 10 ± 0.5 mL of the 0.5M zinc acetate solution, 5.0 ± 0.1 mL of 37% formaldehyde and 100 ± 5.0 mL reagent water.

7.1.2.4 Connect the gas evolution flask and gas scrubbing bottles as shown in Figure 1. Secure all fittings and joints.

7.1.3 Carefully place an accurately weighed sample which contains 0.2 to 50 mg of sulfide into the flask. If necessary, dilute to approximately 200 mL with reagent water.

7.1.4 Place the dropping funnel onto the flask making sure its stopcock is closed. Add the volume of sulfuric acid calculated in Section 7.1.1 plus an additional 50 mL into the dropping funnel. The bottom stopcock must be closed.

7.1.5 Attach the nitrogen inlet to the top of the dropping funnel gas shut-off valve. Turn on the nitrogen purge gas and adjust the flow through the sample flask to 25 mL/min. The nitrogen in the gas scrubbing bottles should bubble at about five bubbles per second. Nitrogen pressure should be limited to approximately 10 psi to prevent excess stress on the glass system and fittings. Verify that there are no leaks in the system. Open the nitrogen shut-off valve leading to the dropping funnel. Observe that the gas flow into the sample vessel will stop for a short period while the pressure throughout the system equalizes. If the gas flow through the sample flask does not return within a minute, check for leaks around the dropping funnel. Once flow has stabilized, turn on magnetic stirrer. Purge system for 15 minutes with nitrogen to remove oxygen.

7.1.6 Heat sample to 70°C. Open dropping funnel to a position that will allow a flow of sulfuric acid of approximately 5 mL/min. Monitor the system until most of the sulfuric acid within the dropping funnel has entered the sample flask. Solids which absorb water and swell will restrict fluid motion and, therefore, lower recovery will be obtained. Such samples should be limited to 25 g dry weight.

7.1.7 Purge, stir, and maintain a temperature of 70°C for a total of 90 minutes from start to finish. Shut off nitrogen supply. Turn off heat.

7.1.8 Quantify the sulfide in the scrubber solution by Method 9034 or by Method 9215.

7.2 Acid-Insoluble Sulfide

7.2.1 As the concentration of HCl during distillation must be within a narrow range for successful distillation of H₂S, the water content must be controlled. It is imperative that the final concentration of HCl in the distillation flask be about 6.5N and that the sample is mostly suspended in the fluid by the action of the stirring bar. This is achieved by adding 50 mL of reagent water, including water in the sample, 100 mL of 9.8N HCl, and the sample to the distillation flask. Solids which absorb water and swell will restrict fluid motion and, therefore, lower recovery will be obtained. Such samples should be limited to 25 g dry weight. Other samples can range from 25 to 50 g.

7.2.2 If the matrix is a dry solid, weigh a portion of the sample such that it contains 0.2 to 50 mg of sulfide. The solid should be crushed to reduce particle size to 1 mm or less. Add 50 mL of reagent water.

7.2.3 If the matrix is aqueous, then a maximum of 50 g of the sample may be used. No additional water may be added. As none of the target compounds are volatile, drying the sample may be preferable to enhance the sensitivity by concentrating the sample. If less than 50 g of the sample is required to achieve the 0.2 to 50 mg of sulfide range for the test, then add reagent water to a total volume of 50 mL.

7.2.4 If the matrix is a moist solid, the water content of the sample must be determined (Karl Fischer titration, loss on drying, or other suitable means) and the water in the sample included in the total 50 mL of water needed for the correct HCl concentration. For example, if a 20 g sample weight is needed to achieve the desired sulfide level of 0.2 to 50 mg and the sample is 50% water then 40 mL rather than 50 mL of reagent water is added along with the sample and 100 mL of 9.8N HCl to the distillation flask.

7.2.5 Weigh the sample and 5 g SnCl_2 into the distillation flask. Use up to 50 mL of reagent water, as calculated above, to rinse any glassware.

7.2.6 Assemble the distillation apparatus as in Figure 1. Place 100 ± 2.0 mL of zinc acetate/sodium acetate buffer solution and 5.0 ± 0.1 mL of 37% formaldehyde in each gas scrubbing bottle. Tighten the pinch clamps on the distillation flask joints.

7.2.7 Make sure the stopcock is closed and then add 100 ± 1.0 mL of 9.8N HCl to the dropping funnel. Connect the nitrogen line to the top of the funnel and turn the nitrogen on to pressurize the dropping funnel headspace.

7.2.8 Set the nitrogen flow at 25 mL/min. The nitrogen in the gas scrubbing bottles should bubble at about five bubbles per second. Purge the oxygen from the system for about 15 minutes.

7.2.9 Turn on the magnetic stirrer. Set the stirring bar to spin as fast as possible. The fluid should form a vortex. If not, the distillation will exhibit poor recovery. Add all of the HCL from the dropping funnel to the flask.

7.2.10 Heat the water bath to the boiling point (100°C). The sample may or may not be boiling. Allow the purged distillation to proceed for 90 minutes at 100°C . Shut off nitrogen supply. Turn off heat.

7.2.11 Quantify the sulfide in the scrubber solution by Method 9034 or by Method 9215.

8.0 QUALITY CONTROL

8.1 All quality control data must be maintained and available for reference or inspection for a period of three years. This method is restricted to use by or under supervision of experienced analysts. Refer to the appropriate section of Chapter One for additional quality control guidelines.

8.2 A reagent blank should be run once in twenty analyses or per analytical batch, whichever is more frequent.

8.3 Check standards are prepared from water and a known amount of sodium sulfide. A check standard should be run with each analytical batch of samples, or once in twenty samples. Acceptable recovery will depend on the level and matrix.

8.4 A matrix spiked sample should be run for each analytical batch or twenty samples, whichever is more frequent, to determine matrix effects. If recovery is low, acid-insoluble sulfides are indicated. A matrix spiked sample is a sample brought through the whole sample preparation and analytical process.

9.0 METHOD PERFORMANCE

9.1 Accuracy - Accuracy for this method was determined by three independent laboratories by measuring percent recoveries of spikes for both clean matrices (water) and actual waste samples. The results are summarized below.

For Acid-Soluble Sulfide

Accuracy of titration step only

Lab A 84-100% recovery

Lab B 110-122% recovery

Accuracy for entire method for clean matrices (H₂O)

Lab C 94-106% recovery

Accuracy of entire method for actual waste samples

Lab C 77-92% recovery

Spiking levels ranged from 0.4 to 8 mg/L

For Acid-Insoluble Sulfide

The percent recovery was not as thoroughly studied for acid-insoluble sulfide as it was for acid-soluble sulfide.

Accuracy of entire method for synthetic waste samples

Lab C 21-81% recovery

Spiking levels ranged from 2.2 to 22 mg/kg

9.2 Precision

For Acid-Soluble Sulfide

Precision of titration step only

Lab A CV% 2.0 to 37

Lab B CV% 1.1 to 3.8

Precision of entire method for clean matrices (H₂O)

Lab C CV% 3.0 to 12

Precision of entire method for actual waste samples

Lab C CV% 0.86 to 45

For Acid-Insoluble Sulfide

Precision of entire method with synthetic wastes

Lab C CV 1.2 to 42

9.3 Detection Limit - The detection limit was determined by analyzing seven replicates at 0.45 and 4.5 mg/L. The detection limit was calculated as the standard deviation times the student's t-value for a one-tailed test with n-1 degrees of freedom at 99% confidence level. The detection limit for a clean matrix (H₂O) was found to be between 0.2 and 0.4 mg/L.

METHOD 9034

TITRIMETRIC PROCEDURE FOR ACID-SOLUBLE AND ACID INSOLUBLE SULFIDES

1.0 SCOPE AND APPLICATION

1.1 This procedure may be used as a determinative step for acid-soluble and acid-insoluble sulfides following distillation of the sample by SW-846 Method 9030.

1.2 Method 9034 is suitable for measuring sulfide concentrations in samples which contain 0.2 mg/kg to 50 mg/kg of sulfide.

2.0 SUMMARY OF METHOD

Sulfide is extracted from the sample by a preliminary distillation procedure (See Method 9030) and precipitated in an zinc acetate scrubber as zinc sulfide. The sulfide is oxidized to sulfur by adding a known excess amount of iodine. The excess iodine is determined by titration with a standard solution of phenyl arsine oxide (PAO) or sodium thiosulfate until the blue iodine starch complex disappears. As the use of standard sulfide solutions is not possible because of oxidative degradation, quantitation is based on the PAO or sodium thiosulfate.

3.0 INTERFERENCES

3.1 The iodometric method suffers interference from reducing substances that react with iodine, including thiosulfate, sulfite, and various organic compounds.

3.2 Refer to Method 9030 for a discussion of other sulfide interferences.

4.0 APPARATUS AND MATERIALS

4.1 500 mL flasks.

4.2 Hot plate stirrer.

4.3 25 mL buret.

4.4 Volumetric pipets.

5.0 REAGENTS

5.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Reagent water. All references to water in this method refer to reagent water, as defined in Chapter One.

5.3 Starch solution - Use either an aqueous solution or soluble starch powder mixtures. Prepare an aqueous solution as follows. Dissolve 2 g soluble starch and 2 g salicylic acid, $C_7H_6O_3$, as a preservative, in 100 mL hot reagent water.

5.4 Iodine solution (approximately 0.025N)

5.5 Dissolve 25 g potassium iodide, KI, in 700 mL of reagent water in a 1-liter volumetric flask. Add 3.2 g iodine, I_2 . Allow to dissolve. Add the type and amount of acid specified in Section 7.3.2. Dilute to 1 liter and standardize as follows.

5.6 Dissolve approximately 2 g KI in 150 mL of reagent water. Add exactly 20 mL of the iodine solution (Section 5.4) to be titrated and dilute to 300 mL with reagent water.

5.6.1 Titrate with 0.025N standardized phenylarsine oxide or 0.025N sodium thiosulfate until the amber color fades to yellow. Add starch indicator solution. Continue titration drop by drop until the blue color disappears.

5.6.2 Run in replicate.

5.6.3 Calculate the normality as follows.

$$\text{Normality (I}_2\text{)} = \frac{\text{mL of titrant} \times \text{normality of titrant}}{\text{sample size in mL}}$$

5.7 Sodium sulfide nonahydrate, $Na_2S \cdot 9H_2O$. For the preparation of standard solutions to be used for calibration curves. Standards must be prepared at $pH > 9$ and < 11 . Protect standard from exposure to oxygen by preparing it without headspace. These standards are unstable and should be prepared daily.

5.8 Titrant.

5.8.1 Standard phenylarsine oxide solution (PAO) (0.025N), C_6H_5AsO . This solution is commercially available.

CAUTION: PAO is toxic.

5.8.2 Standard sodium thiosulfate solution (0.025N), $Na_2S_2O_3 \cdot 5H_2O$. Dissolve 6.205 ± 0.005 g $Na_2S_2O_3 \cdot 5H_2O$ in 500 mL reagent water. Add 9 mL 1N NaOH and dilute to 1 liter.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 Refer to Method 9030 for a discussion of sample collection, preservation, and handling.

6.2 Distillates that are not analyzed immediately should be stored in a sealed flask at 4 °C.

7.0 PROCEDURE

7.1 The following iodometric titration procedure is used to quantify the sulfide concentration in the distillate generated by Method 9030.

7.3.1 Pipet a known amount of standardized 0.025N iodine solution (see Section 5.4) in a 500-mL flask, adding an amount in excess of that needed to oxidize the sulfide. Add enough reagent water to bring the volume to 100 mL. The volume of standardized iodine solution should be about 65 mL for samples with 50 mg of sulfide.

7.3.2 If the distillation for acid-soluble sulfide is being used, add 2 mL of 6N HCl. If the distillation for acid-insoluble sulfides is performed, 10 mL of 6N HCl should be added to the iodine.

7.3.3 Pipet the gas scrubbing solutions obtained in Method 9030 to the flask, keeping the end of the pipet below the surface of the iodine solution. If at any point in transferring the zinc acetate solution or rinsing the bottles, the amber color of the iodine disappears or fades to yellow, more 0.025N iodine must be added. This additional amount must be added to the amount from Section 7.3.1 for calculations. Record the total volume of standardized 0.025N iodine solution used.

7.3.4 Prepare a rinse solution of a known amount of standardized 0.025N iodine solution, 1 mL of 6N HCl, and reagent water to rinse the remaining white precipitate (zinc sulfide) from the gas scrubbing bottles into the flask. There should be no visible traces of precipitate after rinsing.

7.3.5 Rinse any remaining traces of iodine from the gas scrubbing bottles with reagent water, and transfer the rinsate to the flask.

7.3.6 Titrate the solution in the flask with standard 0.025N phenylarsine oxide or 0.025N sodium thiosulfate solution until the amber color fades to yellow. Add enough starch indicator for the solution to turn dark blue and titrate until the blue disappears. Record the volume of titrant used.

7.3.7 Calculate the concentration of sulfide using the following equation:

$$\frac{(\text{mL } I_2 \times N I_2) - (\text{mL titrant} \times N \text{ titrant}) \times \left(\frac{32.06 \text{ g}}{2 \text{ eq.}} \right)}{\text{sample weight (kg) or sample volume (L)}} = \text{sulfide (mg/kg or mg/L)}$$

8.0 QUALITY CONTROL

8.1 All quality control data must be maintained and available for reference or inspection for a period of three years. This method is restricted to use by or under supervision of experienced analysts. Refer to Method 9030 for additional quality control guidelines.

8.2 A reagent blank should be analyzed once in twenty analyses or per analytical batch, whichever is more frequent.

8.3 Check standards are prepared from water and a known amount of sodium sulfide. A check standard should be run with each analytical batch of samples, or once in twenty samples. Acceptable recovery will depend on the level and matrix.

8.4 A matrix spiked sample should be analyzed for each analytical batch or twenty samples, whichever is more frequent, to determine matrix effects. If recovery is low, acid-insoluble sulfides are indicated. A matrix spiked sample is a sample brought through the whole sample preparation and analytical process.

9.0 METHOD PERFORMANCE

9.1 Refer to Method 9030 for data on the precision and accuracy of this method.

DETERMINATION OF PHOSPHORUS BY SEMI-AUTOMATED COLORIMETRY

Edited by James W. O'Dell
Inorganic Chemistry Branch
Chemistry Research Division

Revision 2.0
August 1993

ENVIRONMENTAL MONITORING SYSTEMS LABORATORY
OFFICE OF RESEARCH AND DEVELOPMENT
U.S. ENVIRONMENTAL PROTECTION AGENCY
CINCINNATI, OHIO 45268

METHOD 365.1

DETERMINATION OF PHOSPHORUS BY AUTOMATED COLORIMETRY

1.0 SCOPE AND APPLICATION

- 1.1 This method covers the determination of specified forms of phosphorus in drinking, ground, and surface waters, and domestic and industrial wastes.
- 1.2 The methods are based on reactions that are specific for the orthophosphate ion. Thus, depending on the prescribed pretreatment of the sample, the various forms of phosphorus that may be determined are defined in Section 3.0 and given in Figure 1.
 - 1.2.1 Except for in-depth and detailed studies, the most commonly measured forms are total and dissolved phosphorus, total and dissolved orthophosphate. Hydrolyzable phosphorus is normally found only in sewage-type samples. Insoluble forms of phosphorus are determined by calculation.
- 1.3 The applicable range is 0.01-1.0 mg P/L. Approximately 20-30 samples per hour can be analyzed.

2.0 SUMMARY OF METHOD

- 2.1 Ammonium molybdate and antimony potassium tartrate react in an acid medium with dilute solutions of phosphorus to form an antimony-phosphomolybdate complex. This complex is reduced to an intensely blue-colored complex by ascorbic acid. The color is proportional to the phosphorus concentration.
- 2.2 Only orthophosphate forms a blue color in this test. Polyphosphates (and some organic phosphorus compounds) may be converted to the orthophosphate form by manual sulfuric acid hydrolysis. Organic phosphorus compounds may be converted to the orthophosphate form by manual persulfate digestion.² The developed color is measured automatically.
- 2.3 Reduced volume versions of this method that use the same reagents and molar ratios are acceptable provided they meet the quality control and performance requirements stated in the method.
- 2.4 Limited performance-based method modifications may be acceptable provided they are fully documented and meet or exceed requirements expressed in Section 9.0, Quality Control.

3.0 DEFINITIONS

- 3.1 **Calibration Blank (CB)** -- A volume of reagent water fortified with the same matrix as the calibration standards, but without the analytes, internal standards, or surrogate analytes.
- 3.2 **Calibration Standard (CAL)** -- A solution prepared from the primary dilution standard solution or stock standard solutions and the internal standards and surrogate analytes. The CAL solutions are used to calibrate the instrument response with respect to analyte concentration.
- 3.3 **Instrument Performance Check Solution (IPC)** -- A solution of one or more method analytes, surrogates, internal standards, or other test substances used to evaluate the performance of the instrument system with respect to a defined set of criteria.
- 3.4 **Laboratory Fortified Blank (LFB)** -- An aliquot of reagent water or other blank matrices to which known quantities of the method analytes are added in the laboratory. The LFB is analyzed exactly like a sample, and its purpose is to determine whether the methodology is in control, and whether the laboratory is capable of making accurate and precise measurements.
- 3.5 **Laboratory Fortified Sample Matrix (LFM)** -- An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyzed exactly like a sample, and its purpose is to determine whether the sample matrix contributes bias to the analytical results. The background concentrations of the analytes in the sample matrix must be determined in a separate aliquot and the measured values in the LFM corrected for background concentrations.
- 3.6 **Laboratory Reagent Blank (LRB)** -- An aliquot of reagent water or other blank matrices that are treated exactly as a sample including exposure to all glassware, equipment, solvents, reagents, internal standards, and surrogates that are used with other samples. The LRB is used to determine if method analytes or other interferences are present in the laboratory environment, the reagents, or the apparatus.
- 3.7 **Linear Calibration Range (LCR)** -- The concentration range over which the instrument response is linear.
- 3.8 **Material Safety Data Sheet (MSDS)** -- Written information provided by vendors concerning a chemical's toxicity, health hazards, physical properties, fire, and reactivity data including storage, spill, and handling precautions.
- 3.9 **Method Detection Limit (MDL)** -- The minimum concentration of an analyte that can be identified, measured and reported with 99% confidence that the analyte concentration is greater than zero.
- 3.10 **Quality Control Sample (QCS)** -- A solution of method analytes of known concentrations that is used to fortify an aliquot of LRB or sample matrix. The

QCS is obtained from a source external to the laboratory and different from the source of calibration standards. It is used to check laboratory performance with externally prepared test materials.

- 3.11 **Stock Standard Solution (SSS)** -- A concentrated solution containing one or more method analytes prepared in the laboratory using assayed reference materials or purchased from a reputable commercial source
- 3.12 **Total Phosphorus (P)** -- All of the phosphorus present in the sample regardless of forms, as measured by the persulfate digestion procedure.
 - 3.12.1 Total Orthophosphate (P-ortho) -- Inorganic phosphorus $[(\text{PO}_4)^{-3}]$ in the sample as measured by the direct colorimetric analysis procedure.
 - 3.12.2 Total Hydrolyzable Phosphorus (P-hydro) -- Phosphorus in the sample as measured by the sulfuric acid hydrolysis procedure, and minus predetermined orthophosphates. This hydrolyzable phosphorus includes polyphosphates $[(\text{P}_2\text{O}_7)^{-4}, (\text{P}_3\text{O}_{10})^{-5}, \text{etc.}]$ plus some organic phosphorus.
 - 3.12.3 Total Organic Phosphorus (P-org) -- Phosphorus (inorganic plus oxidizable organic) in the sample as measured by the persulfate digestion procedure, and minus hydrolyzable phosphorus and orthophosphate.
- 3.13 **Dissolved Phosphorus (P-D)** -- All of the phosphorus present in the filtrate of a sample filtered through a phosphorus-free filter of 0.45 micron pore size and measured by the persulfate digestion procedure.
 - 3.13.1 Dissolved Orthophosphate (P-D ortho) -- As measured by the direct colorimetric analysis procedure.
 - 3.13.2 Dissolved Hydrolyzable Phosphorus (P-D, hydro) -- As measured by the sulfuric acid hydrolysis procedure and minus predetermined dissolved orthophosphates.
 - 3.13.3 Dissolved Organic Phosphorus (P-D, org) -- As measured by the persulfate digestion procedure, and minus dissolved hydrolyzable phosphorus and orthophosphate.
- 3.14 The following forms, when sufficient amounts of phosphorus are present in the sample to warrant such consideration, may be calculated:
 - 3.14.1 Insoluble Phosphorus (P-I) = (P) - (P-D).
 - 3.14.1.1 Insoluble Orthophosphate (P-I, ortho) = (P, ortho) - (P-D, ortho).

3.14.1.2 Insoluble Hydrolyzable Phosphorus (P-I, hydro) = (P, hydro) - (P-D, hydro).

3.14.1.3 Insoluble Organic Phosphorus (P-I, org) = (P, org) - (P-D, org).

3.15 All phosphorus forms shall be reported as P, mg/L, to the third place.

4.0 INTERFERENCES

4.1 No interference is caused by copper, iron, or silicate at concentrations many times greater than their reported concentration in seawater. However, high iron concentrations can cause precipitation of, and subsequent loss, of phosphorus.

4.2 The salt error for samples ranging from 5-20% salt content was found to be less than 1%.

4.3 Arsenate is determined similarly to phosphorus and should be considered when present in concentrations higher than phosphorus. However, at concentrations found in sea water, it does not interfere.

4.4 Sample turbidity must be removed by filtration prior to analysis for orthophosphate. Samples for total or total hydrolyzable phosphorus should be filtered only after digestion. Sample color that absorbs in the photometric range used for analysis will also interfere.

4.5 Method interferences may be caused by contaminants in the reagent water, reagents, glassware, and other sample processing apparatus that bias analyte response.

5.0 SAFETY

5.1 The toxicity or carcinogenicity of each reagent used in this method have not been fully established. Each chemical should be regarded as a potential health hazard and exposure should be as low as reasonably achievable. Cautions are included for known extremely hazardous materials or procedures.

5.2 Each laboratory is responsible for maintaining a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method. A reference file of Material Safety Data Sheets (MSDS) should be made available to all personnel involved in the chemical analysis. The preparation of a formal safety plan is also advisable.

5.3 The following chemicals have the potential to be highly toxic or hazardous, consult MSDS.

5.3.1 Sulfuric acid (Sections 7.2 and 7.7)

6.0 EQUIPMENT AND SUPPLIES

- 6.1 Balance -- Analytical, capable of accurately weighing to the nearest 0.0001 g.
- 6.2 Glassware -- Class A volumetric flasks and pipets as required.
- 6.3 Hot plate or autoclave.
- 6.4 Automated continuous flow analysis equipment designed to deliver and react sample and reagents in the required order and ratios.
 - 6.4.1 Sampling device (sampler)
 - 6.4.2 Multichannel pump
 - 6.4.3 Reaction unit or manifold
 - 6.4.4 Colorimetric detector
 - 6.4.5 Data recording device
- 6.5 Acid-washed glassware: All glassware used in the determination should be washed with hot 1:1 HCl and rinsed with distilled water. The acid-washed glassware should be filled with distilled water and treated with all the reagents to remove the last traces of phosphorus that might be adsorbed on the glassware. Preferably, this glassware should be used only for the determination of phosphorus and after use it should be rinsed with distilled water and kept covered until needed again. If this is done, the treatment with 1:1 HCl and reagents is only required occasionally. Commercial detergent should never be used.

7.0 REAGENTS AND STANDARDS

- 7.1 Reagent water: Distilled or deionized water, free of the analyte of interest. ASTM type II or equivalent.
- 7.2 Sulfuric acid solution, 5N: Slowly add 70 mL of conc. H₂SO₄ (CASRN 7664-93-9) to approximately 400 mL of reagent water. Cool to room temperature and dilute to 500 mL with reagent water.
- 7.3 Antimony potassium tartrate solution: Weigh 0.3 g K(SbO)C₄H₄O₆•1/2H₂O (CASRN 28300-74-5) and dissolve in 50 mL reagent water in 100 mL volumetric flask, dilute to volume. Store at 4°C in a dark, glass-stoppered bottle.
- 7.4 Ammonium molybdate solution: Dissolve 4 g (NH₄)₆Mo₇O₂₄•4H₂O (CASRN 12027-67-7) in 100 mL reagent water. Store in a plastic bottle at 4°C.

- 7.5 Ascorbic acid, 0.1M: Dissolve 1.8 g of ascorbic acid (CASRN 50-81-7) in 100 mL of reagent water. The solution is stable for about a week if prepared with water containing no more than trace amounts of heavy metals and stored at 4°C.
- 7.6 Combined reagent: Mix the above reagents in the following proportions for 100 mL of the mixed reagent: 50 mL of 5N H₂SO₄ (Section 7.2), 5 mL of antimony potassium tartrate solution (Section 7.3), 15 mL of ammonium molybdate solution (Section 7.4), and 30 mL of ascorbic acid solution (Section 7.5). Mix after addition of each reagent. All reagents must reach room temperature before they are mixed and must be mixed in the order given. If turbidity forms in the combined reagent, shake and let stand for a few minutes until the turbidity disappears before processing. This volume is sufficient for a four hour operation. Since the stability of this solution is limited, it must be freshly prepared for each run.
- Note:** A stable solution can be prepared by not including the ascorbic acid in the combined reagent. If this is done, the mixed reagent (molybdate, tartrate, and acid) is pumped through the distilled water line and the ascorbic acid solution (30 mL of 7.5 diluted to 100 mL with reagent water) through the original mixed reagent line.
- 7.7 Sulfuric acid solution, 11 N: Slowly add 155 mL conc. H₂SO₄ to 600 mL reagent water. When cool, dilute to 500 mL.
- 7.8 Ammonium persulfate (CASRN 7727-54-0).
- 7.9 Acid wash water: Add 40 mL of sulfuric acid solution (Section 7.7) to 1 L of reagent water and dilute to 2 L. (Not to be used when only orthophosphate is being determined).
- 7.10 Phenolphthalein indicator solution (5 g/L): Dissolve 0.5 g of phenolphthalein (CASRN 77-09-8) in a solution of 50 mL of isopropyl alcohol (CASRN 67-63-0) and 50 mL of reagent water.
- 7.11 Stock phosphorus solution: Dissolve 0.4393 g of predried (105°C for one hour) Potassium phosphate monobasic KH₂PO₄ (CASRN 7778-77-0) in reagent water and dilute to 1000 mL. 1.0 mL = 0.1 mg P.
- 7.12 Standard phosphorus solution: Dilute 10.0 mL of stock solution (Section 7.11) to 100 mL with reagent water. 1.0 mL = 0.01 mg P.
- 7.13 Standard phosphorus solution: Dilute 10.0 mL of standard solution (Section 7.12) to 100 mL with reagent water. 1.0 mL = 0.001 mg P.

8.0 SAMPLE COLLECTION, PRESERVATION AND STORAGE

- 8.1 Samples should be collected in plastic or glass bottles. All bottles must be thoroughly cleaned and rinsed with reagent water. Volume collected should be sufficient to insure a representative sample, allow for replicate analysis (if required), and minimize waste disposal.
- 8.2 Samples must be preserved with H₂SO₄ to a pH <2 and cooled to 4°C at the time of collection.
- 8.3 Samples should be analyzed as soon as possible after collection. If storage is required, preserved samples are maintained at 4°C and may be held for up to 28 days.

9.0 QUALITY CONTROL

- 9.1 Each laboratory using this method is required to operate a formal quality control (QC) program. The minimum requirements of this program consist of an initial demonstration of laboratory capability, and the periodic analysis of laboratory reagent blanks, fortified blanks and other laboratory solutions as a continuing check on performance. The laboratory is required to maintain performance records that define the quality of the data that are generated.
- 9.2 INITIAL DEMONSTRATION OF PERFORMANCE
 - 9.2.1 The initial demonstration of performance is used to characterize instrument performance (determination of LCRs and analysis of QCS) and laboratory performance (determination of MDLs) prior to performing analyses by this method.
 - 9.2.2 Linear Calibration Range (LCR) -- The LCR must be determined initially and verified every six months or whenever a significant change in instrument response is observed or expected. The initial demonstration of linearity must use sufficient standards to insure that the resulting curve is linear. The verification of linearity must use a minimum of a blank and three standards. If any verification data exceeds the initial values by ±10%, linearity must be reestablished. If any portion of the range is shown to be nonlinear, sufficient standards must be used to clearly define the nonlinear portion.
 - 9.2.3 Quality Control Sample (QCS) -- When beginning the use of this method, on a quarterly basis or as required to meet data-quality needs, verify the calibration standards and acceptable instrument performance with the preparation and analyses of a QCS. If the determined concentrations are not within ±10% of the stated values, performance of the determinative step of the method is unacceptable. The source of the problem must be identified and corrected before either proceeding with the initial determination of MDLs or continuing with on-going

analyses.

- 9.2.4 Method Detection Limit (MDL) -- MDLs must be established for all analytes, using reagent water (blank) fortified at a concentration of two to three times the estimated instrument detection limit.⁽⁵⁾ To determine MDL values, take seven replicate aliquots of the fortified reagent water and process through the entire analytical method. Perform all calculations defined in the method and report the concentration values in the appropriate units. Calculate the MDL as follows:

$$\text{MDL} = (t) \times (S)$$

where, t = Student's t value for a 99% confidence level and a standard deviation estimate with n-1 degrees of freedom [t = 3.14 for seven replicates]
 S = standard deviation of the replicate analyses

MDLs should be determined every six months, when a new operator begins work, or whenever there is a significant change in the background or instrument response.

9.3 ASSESSING LABORATORY PERFORMANCE

- 9.3.1 Laboratory Reagent Blank (LRB) -- The laboratory must analyze at least one LRB with each batch of samples. Data produced are used to assess contamination from the laboratory environment. Values that exceed the MDL indicate laboratory or reagent contamination should be suspected and corrective actions must be taken before continuing the analysis.
- 9.3.2 Laboratory Fortified Blank (LFB) -- The laboratory must analyze at least one LFB with each batch of samples. Calculate accuracy as percent recovery (Section 9.4.2). If the recovery of any analyte falls outside the required control limits of 90-110%, that analyte is judged out of control, and the source of the problem should be identified and resolved before continuing analyses.
- 9.3.3 The laboratory must use LFB analyses data to assess laboratory performance against the required control limits of 90-110%. When sufficient internal performance data become available (usually a minimum of 20-30 analyses), optional control limits can be developed from the percent mean recovery (\bar{x}) and the standard deviation (S) of the mean recovery. These data can be used to establish the upper and lower control limits as follows:

$$\begin{aligned}\text{UPPER CONTROL LIMIT} &= \bar{x} + 3S \\ \text{LOWER CONTROL LIMIT} &= \bar{x} - 3S\end{aligned}$$

The optional control limits must be equal to or better than the required control limits of 90-110%. After each five to ten new recovery measurements, new control limits can be calculated using only the most recent 20-30 data points. Also, the standard deviation (S) data should be used to establish an on-going precision statement for the level of concentrations included in the LFB. These data must be kept on file and be available for review.

9.3.4 Instrument Performance Check Solution (IPC) -- For all determinations the laboratory must analyze the IPC (a mid-range check standard) and a calibration blank immediately following daily calibration, after every tenth sample (or more frequently, if required) and at the end of the sample run. Analysis of the IPC solution and calibration blank immediately following calibration must verify that the instrument is within $\pm 10\%$ of calibration. Subsequent analyses of the IPC solution must verify the calibration is still within $\pm 10\%$. If the calibration cannot be verified within the specified limits, reanalyze the IPC solution. If the second analysis of the IPC solution confirms calibration to be outside the limits, sample analysis must be discontinued, the cause determined and/or in the case of drift the instrument recalibrated. All samples following the last acceptable IPC solution must be reanalyzed. The analysis data of the calibration blank and IPC solution must be kept on file with the sample analyses data.

9.4 ASSESSING ANALYTE RECOVERY AND DATA QUALITY

9.4.1 Laboratory Fortified Sample Matrix (LFM) -- The laboratory must add a known amount of analyte to a minimum of 10% of the routine samples. In each case the LFM aliquot must be a duplicate of the aliquot used for sample analysis. The analyte concentration must be high enough to be detected above the original sample and should not be less than four times the MDL. The added analyte concentration should be the same as that used in the laboratory fortified blank.

9.4.2 Calculate the percent recovery for each analyte, corrected for concentrations measured in the unfortified sample, and compare these values to the designated LFM recovery range 90-110%. Percent recovery may be calculate using the following equation:

$$R = \frac{C_s - C}{s} \times 100$$

where, R = percent recovery
C_s = fortified sample concentration
C = sample background concentration
s = concentration equivalent of analyte added to sample

- 9.4.3 If the recovery of any analyte falls outside the designated LFM recovery range and the laboratory performance for that analyte is shown to be in control (Section 9.3), the recovery problem encountered with the LFM is judged to be either matrix or solution related, not system related.
- 9.4.4 Where reference materials are available, they should be analyzed to provide additional performance data. The analysis of reference samples is a valuable tool for demonstrating the ability to perform the method acceptably.

10.0 CALIBRATION AND STANDARDIZATION

- 10.1 Prepare a series of at least three standards, covering the desired range, and a blank by pipetting and diluting suitable volumes of working standard solutions (Section 7.12 or 7.13) into 100 mL volumetric flasks. Suggested ranges include 0.00-0.10 mg/L and 0.20-1.00 mg/L.
- 10.2 Process standards and blanks as described in Section 11.0, Procedure.
- 10.3 Set up manifold as shown in Figure 2.
- 10.4 Prepare flow system as described in Section 11.0, Procedure.
- 10.5 Place appropriate standards in the sampler in order of decreasing concentration and perform analysis.
- 10.6 Prepare standard curve by plotting instrument response against concentration values. A calibration curve may be fitted to the calibration solutions concentration/response data using computer or calculator based regression curve fitting techniques. Acceptance or control limits should be established using the difference between the measured value of the calibration solution and the "true value" concentration.
- 10.7 After the calibration has been established, it must be verified by the analysis of a suitable quality control sample (QCS). If measurements exceed $\pm 10\%$ of the established QCS value, the analysis should be terminated and the instrument recalibrated. The new calibration must be verified before continuing analysis.

Periodic reanalysis of the QCS is recommended as a continuing calibration check.

11.0 PROCEDURE

11.1 Phosphorus

- 11.1.1 Add 1 mL of sulfuric acid solution (Section 7.7) to a 50 mL sample and/or standard in a 125 mL Erlenmeyer flask.
- 11.1.2 Add 0.4 g of ammonium persulfate (Section 7.8).
- 11.1.3 Boil gently on a pre-heated hot plate for approximately 30-40 minutes or until a final volume of about 10 mL is reached. Do not allow sample to go to dryness. Alternately, heat for 30 minutes in an autoclave at 121°C (15-20 psi).
- 11.1.4 Cool and dilute the sample to 50 mL. If sample is not clear at this point, filter.
- 11.1.5 Determine phosphorus as outlined (Section 11.3.2) with acid wash water (Section 7.9) in wash tubes.

11.2 Hydrolyzable Phosphorus

- 11.2.1. Add 1 mL of sulfuric acid solution (Section 7.7) to a 50 mL sample and/or standard in a 125 mL Erlenmeyer flask.
- 11.2.2 Boil gently on a pre-heated hot plate for 30-40 minutes until a final volume of about 10 mL is reached. Do not allow sample to go to dryness. Alternatively, heat for 30 minutes in an autoclave at 121°C (15-20 psi).
- 11.2.3 Determine phosphorus as outlined (Section 11.3.2) with acid wash water (Section 7.9) in wash tubes.

11.3 Orthophosphate

- 11.3.1 Add 1 drop of phenolphthalein indicator solution (Section 7.10) to approximately 50 mL of sample. If a red color develops, add sulfuric acid solution (Section 7.7) drop-wise to just discharge the color. Acid samples must be neutralized with 1 N sodium hydroxide (40 g NaOH/L).
- 11.3.2 Set up manifold as shown in Figure 1.
- 11.3.3 Allow system to equilibrate as required. Obtain a stable baseline with all reagents, feeding reagent water through the sample line.

11.3.4 Place standards in sampler in order of decreasing concentration, and complete filling of sampler tray.

11.3.5 Switch sample line from reagent water to Sampler and begin analysis.

12.0 DATA ANALYSIS AND CALCULATIONS

12.1 Prepare a calibration curve by plotting instrument response against standard concentration. Compute sample concentration by comparing sample response with the standard curve. Multiply answer by appropriate dilution factor.

12.2 Report only those values that fall between the lowest and the highest calibration standards. Samples exceeding the highest standard should be diluted and reanalyzed. Any sample whose computed value is less than 5% of its immediate predecessor must be rerun.

12.3 Report results in mg P/L.

13.0 METHOD PERFORMANCE

13.1 Six laboratories (using Technicon AAI equipment) participating in an EPA Method Study, analyzed four natural water samples containing exact increments of orthophosphate, with the following results:

Increment as Orthophosphate mg P/L	Precision as Standard Deviation mg P/L	Accuracy As	
		Bias %	Bias mg P/L
—	—	—	—
0.04	0.019	+16.7	+0.007
0.04	0.014	-8.3	-0.003
0.29	0.087	-15.5	-0.05
0.30	0.066	-12.8	-0.04

13.2 In a single laboratory (EMSL), using surface water samples at concentrations of 0.04, 0.19, 0.35, and 0.84 mg P/L, standard deviations were ± 0.005 , ± 0.000 , ± 0.003 , and ± 0.000 , respectively.

13.3 In a single laboratory (EMSL), using surface water samples at concentrations of 0.07 mg and 0.76 mg P/L, recoveries were 99% and 100%, respectively.

13.4 The interlaboratory precision and accuracy data in Table 1 were developed using a reagent water matrix. Values are in mg PO₄-P/L.

14.0 POLLUTION PREVENTION

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity or toxicity of waste at the point of generation. Numerous

opportunities for pollution prevention exist in laboratory operation. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.

- 14.2 The quantity of chemicals purchased should be based on expected usage during its shelf life and disposal cost of unused material. Actual reagent preparation volumes should reflect anticipated usage and reagent stability.
- 14.3 For information about pollution prevention that may be applicable to laboratories and research institutions, consult "Less is Better: Laboratory Chemical Management for Waste Reduction", available from the American Chemical Society's Department of Government Regulations and Science Policy, 1155 16th Street N.W., Washington, D.C. 20036, (202) 872-4477.

15.0 WASTE MANAGEMENT

- 15.1 The Environmental Protection Agency requires that laboratory waste management practices be conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes should be characterized and disposed of in an acceptable manner. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods, and bench operations, complying with the letter and spirit of any waster discharge permit and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management consult the "Waste Management Manual for Laboratory Personnel", available from the American Chemical Society at the address listed in Section 14.3.

Total Kjeldahl Nitrogen

USEPA Method 351.2

METHOD 351.2

DETERMINATION OF TOTAL KJELDAHL NITROGEN BY SEMI-AUTOMATED COLORIMETRY

Edited by James W. O'Dell
Inorganic Chemistry Branch
Chemistry Research Division

Revision 2.0
August 1993

ENVIRONMENTAL MONITORING SYSTEMS LABORATORY
OFFICE OF RESEARCH AND DEVELOPMENT
U.S. ENVIRONMENTAL PROTECTION AGENCY
CINCINNATI, OHIO 45268

METHOD 351.2

DETERMINATION OF TOTAL KJELDAHL NITROGEN BY SEMI-AUTOMATED COLORIMETRY

1.0 SCOPE AND APPLICATION

- 1.1 This method covers the determination of total Kjeldahl nitrogen in drinking, ground, and surface waters, domestic and industrial wastes. The procedure converts nitrogen components of biological origin such as amino acids, proteins and peptides to ammonia, but may not convert the nitrogenous compounds of some industrial wastes such as amines, nitro compounds, hydrazones, oximes, semicarbazones and some refractory tertiary amines.
- 1.2 The applicable range is 0.1-20 mg/L TKN. The range may be extended with sample dilution.

2.0 SUMMARY OF METHOD

- 2.1 The sample is heated in the presence of sulfuric acid, H_2SO_4 for two and one half hours. The residue is cooled, diluted to 25 mL and analyzed for ammonia. This digested sample may also be used for phosphorus determination.
- 2.2 Total Kjeldahl nitrogen is the sum of free-ammonia and organic nitrogen compounds which are converted to ammonium sulfate $(NH_4)_2SO_4$, under the conditions of digestion described.
- 2.3 Organic Kjeldahl nitrogen is the difference obtained by subtracting the free-ammonia value from the total Kjeldahl nitrogen value.
- 2.4 Reduced volume versions of this method that use the same reagents and molar ratios are acceptable provided they meet the quality control and performance requirements stated in the method.
- 2.5 Limited performance-based method modifications may be acceptable provided they are fully documented and meet or exceed requirements expressed in Section 9.0, Quality Control.

3.0 DEFINITIONS

- 3.1 **Calibration Blank (CB)** -- A volume of reagent water fortified with the same matrix as the calibration standards, but without the analytes, internal standards, or surrogate analytes.
- 3.2 **Calibration Standard (CAL)** -- A solution prepared from the primary dilution standard solution or stock standard solutions and the internal standards and

surrogate analytes. The CAL solutions are used to calibrate the instrument response with respect to analyte concentration.

- 3.3 **Instrument Performance Check Solution (IPC)** -- A solution of one or more method analytes, surrogates, internal standards, or other test substances used to evaluate the performance of the instrument system with respect to a defined set of criteria.
- 3.4 **Laboratory Fortified Blank (LFB)** -- An aliquot of reagent water or other blank matrices to which known quantities of the method analytes are added in the laboratory. The LFB is analyzed exactly like a sample, and its purpose is to determine whether the methodology is in control, and whether the laboratory is capable of making accurate and precise measurements.
- 3.5 **Laboratory Fortified Sample Matrix (LFM)** -- An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyzed exactly like a sample, and its purpose is to determine whether the sample matrix contributes bias to the analytical results. The background concentrations of the analytes in the sample matrix must be determined in a separate aliquot and the measured values in the LFM corrected for background concentrations.
- 3.6 **Laboratory Reagent Blank (LRB)** -- An aliquot of reagent water or other blank matrices that are treated exactly as a sample including exposure to all glassware, equipment, solvents, reagents, internal standards, and surrogates that are used with other samples. The LRB is used to determine if method analytes or other interferences are present in the laboratory environment, the reagents, or the apparatus.
- 3.7 **Linear Calibration Range (LCR)** -- The concentration range over which the instrument response is linear.
- 3.8 **Material Safety Data Sheet (MSDS)** -- Written information provided by vendors concerning a chemical's toxicity, health hazards, physical properties, fire, and reactivity data including storage, spill, and handling precautions.
- 3.9 **Method Detection Limit (MDL)** -- The minimum concentration of an analyte that can be identified, measured and reported with 99% confidence that the analyte concentration is greater than zero.
- 3.10 **Quality Control Sample (QCS)** -- A solution of method analytes of known concentrations that is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained from a source external to the laboratory and different from the source of calibration standards. It is used to check laboratory performance with externally prepared test materials.

- 3.11 **Stock Standard Solution (SSS)** -- A concentrated solution containing one or more method analytes prepared in the laboratory using assayed reference materials or purchased from a reputable commercial source.

4.0 INTERFERENCES

- 4.1 High nitrate concentrations (10X or more than the TKN level) result in low TKN values. If interference is suspected, samples should be diluted and reanalyzed.
- 4.2 Method interferences may be caused by contaminants in the reagent water, reagents, glassware, and other sample processing apparatus that bias analyte response.

5.0 SAFETY

- 5.1 The toxicity or carcinogenicity of each reagent used in this method have not been fully established. Each chemical should be regarded as a potential health hazard and exposure should be as low as reasonably achievable. Cautions are included for known extremely hazardous materials or procedures.
- 5.2 Each laboratory is responsible for maintaining a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method. A reference file of Material Safety Data Sheets (MSDS) should be made available to all personnel involved in the chemical analysis. The preparation of a formal safety plan is also advisable.
- 5.3 The following chemicals have the potential to be highly toxic or hazardous, consult MSDS.
- 5.3.1 Mercury (Sections 7.2 and 7.3)
 - 5.3.2 Sulfuric acid (Sections 7.2, 7.3, and 7.4)
 - 5.3.3 Sodium nitroprusside (Section 7.9)

6.0 EQUIPMENT AND SUPPLIES

- 6.1 Balance - Analytical, capable of accurately weighing to the nearest 0.0001 g.
- 6.2 Glassware - Class A volumetric flasks and pipets as required.
- 6.3 Block digester with tubes.
- 6.4 Automated continuous flow analysis equipment designed to deliver and react sample and reagents in the required order and ratios.
- 6.4.1 Sampling device (sampler)

- 6.4.2 Multichannel pump
- 6.4.3 Reaction unit or manifold
- 6.4.4 Colorimetric detector
- 6.4.5 Data recording device

7.0 REAGENTS AND STANDARDS

- 7.1 Reagent water: Ammonia free distilled or deionized water, free of the analyte of interest. ASTM Type II or equivalent.
- 7.2 Mercuric sulfate: Dissolve 8 g red mercuric oxide (HgO) (CASRN 21908-53-2) in 50 mL of 1:4 sulfuric acid (10 mL conc. H₂SO₄; [CASRN 7664-93-9] 40 mL reagent water) and dilute to 100 mL with reagent water.
- 7.3 Digestion solution: (Sulfuric acid-mercuric sulfate-potassium sulfate solution): Dissolve 133 g of K₂SO₄ (CASRN 7778-80-5) in 700 mL of reagent water and 200 mL of conc. H₂SO₄. Add 25 mL of mercuric sulfate solution (Section 7.1) and dilute to 1 L.

Note 1: An alternate mercury-free digestion solution can be prepared by dissolving 134 g K₂SO₄ and 7.3 g CuSQ in 800 mL reagent water and then adding 134 mL conc. H₂SO₄ and diluting to 1 L. Use 10 mL solution per 25 mL of sample.
- 7.4 Sulfuric Acid solution (4%): Add 40 mL of conc. sulfuric acid to 800 mL of reagent water, cool and dilute to 1 L.

Note 2: If alternate mercury-free digestion solution is used, adjust the above solution to equal the acid concentration of the digested sample (Section 11.6).
- 7.5 Stock Sodium Hydroxide (20%): Dissolve 200 g of sodium hydroxide (CASRN 1310-73-2) in 900 mL of reagent water and dilute to 1 L.
- 7.6 Stock Sodium Potassium Tartrate solution (20%): Dissolve 200 g sodium potassium tartrate (CASRN 6381-59-5) in about 800 mL of reagent water and dilute to 1 L.
- 7.7 Stock Buffer solution: Dissolve 134.0 g of sodium phosphate, dibasic (Na₂HPO₄) (CASRN 7558-79-4) in about 800 mL of reagent water. Add 20 g of sodium hydroxide and dilute to 1 L.
- 7.8 Working Buffer solution: Combine the reagents in the stated order, add 250 mL of stock sodium potassium tartrate solution (Section 7.6) to 200 mL of stock buffer solution (Section 7.7) and mix. Add xx mL sodium hydroxide solution

(Section 7.5) and dilute to 1 L. See concentration ranges, Table 2, for composition of working buffer.

- 7.9 Sodium Salicylate/Sodium Nitroprusside solution: Dissolve 150 g of sodium salicylate (CASRN 54-21-7) and 0.3 g of sodium nitroprusside (CASRN 13755-38-9 or 14402-89-2) in about 600 mL of reagent water and dilute to 1 L.
- 7.10 Sodium Hypochlorite solution: Dilute 6.0 mL sodium hypochlorite solution (CASRN 7681-52-9) (Clorox) to 100 mL with reagent water.
- 7.11 Ammonium chloride, stock solution: Dissolve 3.819 g NH_4Cl (CASRN 12125-02-9) in reagent water and bring to volume in a 1 L volumetric flask. 1 mL = 1.0 mg $\text{NH}_3\text{-N}$.
- 7.12 Teflon boiling chips.

8.0 SAMPLE COLLECTION, PRESERVATION AND STORAGE

- 8.1 Samples should be collected in plastic or glass bottles. All bottles must be thoroughly cleaned and rinsed with reagent water. Volume collected should be sufficient to insure a representative sample, allow for replicate analysis (if required), and minimize waste disposal.
- 8.2 Samples must be preserved with H_2SO_4 to a pH <2 and cooled to 4°C at the time of collection.
- 8.3 Samples should be analyzed as soon as possible after collection. If storage is required, preserved samples are maintained at 4°C and may be held for up to 28 days.

9.0 QUALITY CONTROL

- 9.1 Each laboratory using this method is required to operate a formal quality control (QC) program. The minimum requirements of this program consist of an initial demonstration of laboratory capability, and the periodic analysis of laboratory reagent blanks, fortified blanks and other laboratory solutions as a continuing check on performance. The laboratory is required to maintain performance records that define the quality of the data that are generated.
- 9.2 INITIAL DEMONSTRATION OF PERFORMANCE
 - 9.2.1 The initial demonstration of performance is used to characterize instrument performance (determination of linear calibration ranges and analysis of QCS) and laboratory performance (determination of MDLs) prior to performing analyses by this method.
 - 9.2.2 Linear Calibration Range (LCR) -- The LCR must be determined initially and verified every 6 months or whenever a significant change

in instrument response is observed or expected. The initial demonstration of linearity must use sufficient standards to insure that the resulting curve is linear. The verification of linearity must use a minimum of a blank and three standards. If any verification data exceeds the initial values by $\pm 10\%$, linearity must be reestablished. If any portion of the range is shown to be nonlinear, sufficient standards must be used to clearly define the nonlinear portion.

9.2.3 Quality Control Sample (QCS) -- When beginning the use of this method, on a quarterly basis, or as required to meet data-quality needs, verify the calibration standards and acceptable instrument performance with the preparation and analyses of a QCS. If the determined concentrations are not within $\pm 10\%$ of the stated values, performance of the determinative step of the method is unacceptable. The source of the problem must be identified and corrected before either proceeding with the initial determination of MDLs or continuing with on-going analyses.

9.2.4 Method Detection Limit (MDL) -- MDLs must be established for all analytes, using reagent water (blank) fortified at a concentration of two to three times the estimated instrument detection limit.⁽⁶⁾ To determine MDL values, take seven replicate aliquots of the fortified reagent water and process through the entire analytical method. Perform all calculations defined in the method and report the concentration values in the appropriate units. Calculate the MDL as follows:

$$\text{MDL} = (t) \times (S)$$

where, t = Student's t value for a 99% confidence level and a standard deviation estimate with $n-1$ degrees of freedom [$t = 3.14$ for seven replicates]
 S = standard deviation of the replicate analyses

MDLs should be determined every six months, when a new operator begins work, or whenever there is a significant change in the background or instrument response.

9.3 ASSESSING LABORATORY PERFORMANCE

9.3.1 Laboratory Reagent Blank (LRB) -- The laboratory must analyze at least one LRB with each batch of samples. Data produced are used to assess contamination from the laboratory environment. Values that exceed the MDL indicate laboratory or reagent contamination should be suspected and corrective actions must be taken before continuing the analysis.

- 9.3.2 Laboratory Fortified Blank (LFB) -- The laboratory must analyze at least one LFB with each batch of samples. Calculate accuracy as percent recovery (Section 9.4.2). If the recovery of any analyte falls outside the required control limits of 90-110%, that analyte is judged out of control, and the source of the problem should be identified and resolved before continuing analyses.
- 9.3.3 The laboratory must use LFB analyses data to assess laboratory performance against the required control limits of 90-110%. When sufficient internal performance data become available (usually a minimum of 20-30 analyses), optional control limits can be developed from the percent mean recovery (\bar{x}) and the standard deviation (S) of the mean recovery. These data can be used to establish the upper and lower control limits as follows:

$$\begin{aligned}\text{UPPER CONTROL LIMIT} &= \bar{x} + 3S \\ \text{LOWER CONTROL LIMIT} &= \bar{x} - 3S\end{aligned}$$

The optional control limits must be equal to or better than the required control limits of 90-110%. After each five to ten new recovery measurements, new control limits can be calculated using only the most recent 20-30 data points. Also, the standard deviation (S) data should be used to establish an on-going precision statement for the level of concentrations included in the LFB. These data must be kept on file and be available for review.

- 9.3.4 Instrument Performance Check Solution (IPC) -- For all determinations the laboratory must analyze the IPC (a mid-range check standard) and a calibration blank immediately following daily calibration, after every 10th sample (or more frequently, if required), and at the end of the sample run. Analysis of the IPC solution and calibration blank immediately following calibration must verify that the instrument is within $\pm 10\%$ of calibration. Subsequent analyses of the IPC solution must verify the calibration is still within $\pm 10\%$. If the calibration cannot be verified within the specified limits, reanalyze the IPC solution. If the second analysis of the IPC solution confirms calibration to be outside the limits, sample analysis must be discontinued, the cause determined and/or in the case of drift the instrument recalibrated. All samples following the last acceptable IPC solution must be reanalyzed. The analysis data of the calibration blank and IPC solution must be kept on file with the sample analyses data.

9.4 ASSESSING ANALYTE RECOVERY AND DATA QUALITY

- 9.4.1 Laboratory Fortified Sample Matrix (LFM) -- The laboratory must add a known amount of analyte to a minimum of 10% of the routine samples. In each case the LFM aliquot must be a duplicate of the aliquot used for sample analysis. The analyte concentration must be high enough to

be detected above the original sample and should not be less than four times the MDL. The added analyte concentration should be the same as that used in the laboratory fortified blank.

- 9.4.2 Calculate the percent recovery for each analyte, corrected for concentrations measured in the unfortified sample, and compare these values to the designated LFM recovery range 90-110%. Percent recovery may be calculated using the following equation:

$$R = \frac{C_s - C}{s} \times 100$$

where, R = percent recovery
C_s = fortified sample concentration
C = sample background concentration
s = concentration equivalent of analyte added to sample

- 9.4.3 If the recovery of any analyte falls outside the designated LFM recovery range and the laboratory performance for that analyte is shown to be in control (Section 9.3), the recovery problem encountered with the LFM is judged to be either matrix or solution related, not system related.
- 9.4.4 Where reference materials are available, they should be analyzed to provide additional performance data. The analysis of reference samples is a valuable tool for demonstrating the ability to perform the method acceptably.

10.0 CALIBRATION AND STANDARDIZATION

- 10.1 Prepare a series of at least three standards, covering the desired range, and a blank by diluting suitable volumes of standard solution (Section 7.11) with reagent water.
- 10.2 Process standards and blanks as described in Section 11.0, Procedure.
- 10.3 Set up manifold as shown in Figure 1 and Table 2.
- 10.4 Prepare flow system as described in Section 11.0, Procedure.
- 10.5 Place appropriate standards in the sampler in order of decreasing concentration and perform analysis.
- 10.6 Prepare standard curve by plotting instrument response against concentration values. A calibration curve may be fitted to the calibration solutions concentration/response data using computer or calculator based regression curve fitting techniques. Acceptance or control limits should be established

using the difference between the measured value of the calibration solution and the "true value" concentration.

- 10.7 After the calibration has been established, it must be verified by the analysis of a suitable quality control sample (QCS). If measurements exceed $\pm 10\%$ of the established QCS value, the analysis should be terminated and the instrument recalibrated. The new calibration must be verified before continuing analysis. Periodic reanalysis of the QCS is recommended as a continuing calibration check.

11.0 PROCEDURE

- 11.1 Pipet 25.0 mL of sample, standard or blank in the digester tube.
- 11.2 Add 5 mL of digestion solution (Section 7.3) and mix with a vortex mixer (See Note 1).
- 11.3 Add four to eight Teflon boiling chips (Section 7.12). **CAUTION:** An excess of Teflon chips may cause the sample to boil over.
- 11.4 Place tubes in block digester preheated to 160°C and maintain temperature for one hour.
- 11.5 Reset temperature to 380°C and continue to heat for one and one half hour.
(380°C MUST BE MAINTAINED FOR 30 MINUTES)
- 11.6 Remove digestion tubes, cool and dilute to 25 mL with reagent water.
- 11.7 Excluding the salicylate line, place all reagent lines in their respective containers, connect the sample probe to the sampler and start the pump.
- 11.8 Flush the sampler wash receptacle with about 25 mL of 4% sulfuric acid (Section 7.4) (See Note 2).
- 11.9 When reagents have been pumping for at least five minutes, place the salicylate line in its respective container and allow the system to equilibrate. If a precipitate forms after the addition of salicylate, the pH is too low. Immediately stop the proportioning pump and flush the coils with water using a syringe. Before restarting the system, check the concentration of the sulfuric acid solutions and/or the working buffer solution.
- 11.10 To prevent precipitation of sodium salicylate in the waste tray, which can clog the tray outlet, keep the nitrogen flowcell pump tube and the nitrogen Colorimeter "To Waste" tube separate from all other lines or keep tap water flowing in the waste tray.

- 11.11 After a stable baseline has been obtained, start the sampler and perform analysis.

12.0 DATA ANALYSIS AND CALCULATIONS

- 12.1 Prepare a calibration curve by plotting instrument response against standard concentration. Compute sample concentration by comparing sample response with the standard curve. Multiply answer by appropriate dilution factor.
- 12.2 Report only those values that fall between the lowest and the highest calibration standards. Samples exceeding the highest standard should be diluted and reanalyzed.
- 12.3 Report results in mg N/L.

13.0 METHOD PERFORMANCE

- 13.1 In a single laboratory (EMSL-Cincinnati) using sewage samples at concentrations of 1.2, 2.6, and 1.7 mg N/L, the precision was ± 0.07 , ± 0.03 , and ± 0.15 , respectively.
- 13.2 In a single laboratory (EMSL-Cincinnati) using sewage samples at concentrations 4.7 and 8.74 mg N/L, the recoveries were 99% and 99%, respectively.
- 13.3 The interlaboratory precision and accuracy data in Table 1 were developed using a reagent water matrix. Values are in mg N/L.

14.0 POLLUTION PREVENTION

- 14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity or toxicity of waste at the point of generation. Numerous opportunities for pollution prevention exist in laboratory operation. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.
- 14.2 The quantity of chemicals purchased should be based on expected usage during its shelf life and disposal cost of unused material. Actual reagent preparation volumes should reflect anticipated usage and reagent stability.
- 14.3 For information about pollution prevention that may be applicable to laboratories and research institutions, consult "Less is Better: Laboratory Chemical Management for Waste Reduction", available from the American

15.0 WASTE MANAGEMENT

- 15.1 The Environmental Protection Agency requires that laboratory waste management practices be conducted consistent with all applicable rules and regulations. Excess Reagents and samples and method process wastes should be characterized and disposed of in an acceptable manner. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods and bench operations, complying with the letter and spirit of any waste discharge permit and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management consult "The Waste Management Manual for Laboratory Personnel", available from the American Chemical Society at the address listed in Section 14.3.

DETERMINATION OF ACID VOLATILE SULFIDE AND SELECTED SIMULTANEOUSLY EXTRACTABLE METALS IN SEDIMENT

1. SCOPE AND APPLICATION

- 1.1 This method describes procedures for the determination of acid volatile sulfide (AVS) and for selected metals that are solubilized during the acidification step (simultaneously extracted metal, SEM). As a precipitant of toxic heavy metals, sulfide is important in controlling the bioavailability of metals in anoxic sediments (1). Research has established that the relative amounts of SEM and AVS are important in the prediction of potential metal bioavailability; if the molar ratio of SEM for bivalent metals to AVS exceeds one, the toxic heavy metals in that sample are potentially bioavailable. This method uses the same conditions for release of both sulfide and metal from the sediment and thus provides a useful means of assessing the amount of metal associated with sulfide.

2. SUMMARY OF METHOD

- 2.1 The AVS in the sample is first converted to hydrogen sulfide (H_2S) by acidification with hydrochloric acid at room temperature. The H_2S is then purged from the sample and trapped in aqueous solution. The amount of sulfide that has been trapped is then determined. The SEM are selected metals liberated from the sediment during the acidification. These are determined after filtration of the sample.
- 2.2 Two types of apparatus for sample purging and trapping of H_2S are described. One uses a series of Erlenmeyer flasks while the other uses flasks and traps with ground glass stoppers. The former is less costly. The latter is less prone to leakage that causes low recovery of AVS. The latter is recommended when higher degrees of precision are desired and for samples containing low levels of AVS.
- 2.3 Three means of quantifying the H_2S released by acidifying the sample are provided. The colorimetric method is generally preferred. In the gravimetric procedure, the H_2S is trapped in silver nitrate. The silver sulfide that is formed is determined by weighing (1, 2). This procedure can be used for samples with moderate or high AVS concentrations. Below 10 μ moles AVS/gram dry sediment, accuracy may be affected by incomplete recovery of precipitate and by weighing errors. In the colorimetric method, the H_2S is trapped in sodium hydroxide. The sulfide reacts with N-N-dimethyl-p-phenylenediamine to form methylene blue that is measured (3). This procedure is capable of determining AVS concentrations as low as 0.01 μ moles/gram dry weight of sediment. By appropriate sample dilution, the maximum concentration of

AVS which can be determined is at least 1000 μ moles/gram dry sediment. In an alternative procedure the H_2S is trapped in an antioxidant buffer before using an ion-selective electrode (4, 5).

- 2.4 After release of the H_2S , the acidified sediment sample is membrane filtered before determination of the SEM by atomic absorption or inductive coupled plasma spectrometric methods (6, 7).

3. DEFINITIONS

- 3.1 **ACID VOLATILE SULFIDE (AVS)** - AVS is operationally defined as sulfides that form hydrogen sulfide under the conditions of this test. This includes amorphous, moderately crystalline monosulfides, and other sulfides (8).
- 3.2 **SIMULTANEOUSLY EXTRACTED METALS (SEM)** - SEM are operationally defined as metals, commonly cadmium, copper, lead, mercury, nickel and zinc, that form less soluble sulfides than do iron or manganese, and which are at least partially soluble under the conditions of this test.
- 3.3 **METHOD DETECTION LIMIT (MDL)** - The minimum concentration of an analyte that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from the analysis of a sample that contains the analyte within a given matrix.
- 3.4 **LABORATORY REAGENT BLANK (LRB)** - An aliquot of reagent water or reagents that is treated exactly as a sample including exposure to all glassware, equipment, and reagents that are used with samples. The LRB is used to determine if method analytes or other interferences are present in the laboratory environment, reagents or apparatus.
- 3.5 **STOCK STANDARD SOLUTION** - A concentrated solution of the analyte prepared in the laboratory using assayed reference compounds or purchased from a reputable commercial source.
- 3.6 **CALIBRATION STANDARDS** - Solutions prepared from the stock standard solution that is used to calibrate the method response with respect to analyte concentration.
- 3.7 **LABORATORY FORTIFIED BLANK (LFB)** - An aliquot of reagent water or reagents to which a known quantity of the method analyte is added in the laboratory. The LFB is analyzed exactly like a sample. Its purpose is to determine whether the method is within accepted control limits.
- 3.8 **LABORATORY FORTIFIED SAMPLE MATRIX (LFM)** - An environmental sample to which a known quantity of the method analyte is added in the laboratory. The LFM is

analyzed exactly like a sample. Its purpose is to determine whether the sample matrix contributes bias to the analytical results.

4. INTERFERENCES

- 4.1 Contact with oxygen must be avoided in all stages from sampling to analysis. Consequently, the samples and standards should be protected from air from the time of sampling through the analytical procedure. This can be achieved by deaerating and maintaining the samples under nitrogen or argon at all times.

5. SAFETY

- 5.1 The toxicity or carcinogenicity of reagents used in this method have not been fully established. Each chemical and environmental sample should be regarded as a potential health hazard and exposure should be minimized. Each laboratory is responsible for maintaining a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method. A reference file of material safety data sheets should be available to all personnel involved in the chemical analysis.
- 5.2 Hydrogen sulfide is a highly poisonous, gaseous compound having a characteristic odor of rotten eggs. It is detectable in air by humans at a concentration of approximately 0.002 ppm. Handling of acid samples should be performed in a hood or well ventilated area. If a high concentration of hydrogen sulfide is detected in the air by the laboratory staff, sample handling procedures must be corrected. According to Sax (9) an air concentration of 10 ppm of H₂S is permitted for an 8 hour shift for 40 hours per week.
- 5.3 If samples originate from a highly contaminated area, appropriate sample handling procedures to minimize worker exposure must be followed.

6. APPARATUS AND EQUIPMENT

6.1 Glassware

6.1.1 AVS evolution and H₂S trapping - Glassware in Section 6.1.1.1 is recommended. Glassware in Section 6.1.1.2 may be used, but will not provide as high precision or accuracy for samples.

6.1.1.1 For highest precision and low AVS levels - For each analytical train 500 mL gas washing bottles or oxygen trap, one 250 mL round bottom flask with a septum (Ace Glass 6934 or equivalent), 100 or

250 mL impingers with non-fritted outlets. The round bottom flask contains the sediment and acid is introduced to it by a syringe inserted through the septum. The flasks are connected by tubing. Because sulfide may react with tubing and other surfaces, minimum lengths of tubing should be used as sleeves to connect the glass tubing. The analyst should pay particular attention to the recovery of sulfide from standards in evaluating the apparatus. In all cases the inlets are below the liquid level and the outlets are above the liquid levels. The apparatus is assembled as shown in Figure 1 and more than one analytical train can be connected to a single cylinder of nitrogen or argon if flow controllers are installed in the line. Different amounts of glassware are required for each of the three means of sulfide determination.

Figure 1. Apparatus for AVS determination: 1. N_2 or Ar cylinder; 2. Gas washing bottles: (a) oxygen scrubbing solution or an oxygen trap may be used in replacement of this gas washing bottle, (b) deionized water; 3. Three-way stopcock; 4. Flow controller; 5. Reaction flask; 6. Magnetic stirrer; 7. Impingers with non-fritted outlets.

6.1.1.2 For routine analysis - Erlenmeyer flasks, 250 mL, are substituted for the gas washing bottle, the round bottom flask and the impingers. The flask size should be consistent with sample size and reagent volumes. A thistle tube fitted with a stopcock or a separatory funnel is provided to introduce acid to the flask containing the sediment sample. This flask is fitted with a three hole stopper. One hole is for the thistle tube or separatory funnel and the other two are for the gas inlet and

outlet. The other flasks are fitted with two hole stoppers; one hole is for the gas inlet and the other is for the gas outlet. The gas inlets are below the liquid level and the gas outlets are above the liquid level. The flasks are connected by tubing. Because sulfide may react with tubing, stoppers and other surfaces, minimum lengths of tubing should be used as sleeves to connect the glass tubing. The analyst should pay particular attention to the recovery of sulfide from standards in evaluating the apparatus.

- 6.1.2 Evaporating dishes, porcelain, 100 mL.
- 6.1.3 Assorted calibrated pipettes and volumetric flasks.
- 6.2 Drying oven - Capable of maintaining a constant temperature in the range of 103-105°C.
- 6.3 Analytical balance - capable of weighing to 0.0001 g.
- 6.4 Magnetic stirrer, thermally insulated, and Teflon-coated stirring bar.
- 6.5 Gravimetric method
 - 6.5.1 Filtering flask.
 - 6.5.2 Filter holder for 47 mm filter.
- 6.6 Colorimetric method
 - 6.6.1 Spectrophotometer - Capable of measuring absorbance at 670 nm.
 - 6.6.2 Spectrophotometer cells.
- 6.7 Ion-selective electrode method
 - 6.7.1 Electrometer, pH meter or ion-selective meter - Compatible with the use of ion-selective electrodes.
 - 6.7.2 Sulfide selective electrode.
 - 6.7.3 Double-junction reference electrode.
- 6.8 Atomic absorption or inductive couple plasma spectrophotometer for the determination of SEM.

7. REAGENTS AND CONSUMABLE MATERIALS

- 7.1 All water and reagents used in this method must be free of dissolved oxygen and sulfide. Freshly prepare and use deaerated, deionized water by removing dissolved

oxygen from the deionized water by vigorously bubbling with oxygen-free nitrogen or argon for approximately one hour. Deaerate reagents immediately before use by deaerating with oxygen-free nitrogen or argon.

7.2 Sodium sulfide standard - Required for quality assurance and calibration.

7.2.1 Sulfide stock standard solution, approximately 0.05M or 50 $\mu\text{moles/mL}$.

7.2.1.1 Weigh about 12 gram of $\text{Na}_2\text{S}\cdot 9\text{H}_2\text{O}$ and dissolve it in 1,000 mL of deionized water. Store in a brown bottle. To prevent air oxidation, the sulfide solution should be maintained under oxygen-free nitrogen or argon.

7.2.1.2 Standardize against thiosulfate solution.

7.2.1.2.1 Pipette 10.00 mL of 0.025N standard iodine solution (Section 7.2.2) into each of two 125-mL Erlenmeyer flasks.

7.2.1.2.2 Pipette 2.00 mL of sulfide stock standard solution into one flask. Pipette 2.00 mL of deionized water, as a laboratory reagent blank, into the other flask.

7.2.1.2.3 Add 5.00 mL of 6M HCl into each flask, swirl slightly, then cover and place in the dark for 5 minutes.

7.2.1.2.4 Titrate each with 0.025N thiosulfate (Section 7.2.3) until the yellow iodine color fades to a pale straw. Just before all the iodine has been titrated, add starch indicator (Section 7.2.4) dropwise to form a pale blue color. Continue the titration with the thiosulfate. The end point is reached when the blue color first disappears.

7.2.1.2.5 Calculate the sulfide concentration as follows:

$$\text{Sulfide } (\mu\text{mol / mL}) = \frac{(T_{\text{blank}} - T_{\text{sample}}) \times N_{\text{S}_2\text{O}_3^{2-}}}{V_{\text{sample}}} \times \frac{1 \text{ mole S}^{2-}}{2 \text{ equiv S}^{2-}} \times \frac{1000 \mu\text{moles}}{1 \text{ mmole}}$$

where T = volume of titrant used for the blank and sample (mL)

N = concentration of $\text{S}_2\text{O}_3^{2-}$ titrant

V = volume of sample used (mL), 2.00 mL recommended

7.2.2 Standard iodine solution, 0.025N - Dissolve 20 to 25 gram potassium iodide, KI, in a small volume of deionized water, add 3.2 gram iodine, and dilute to 1,000 mL. Standardize against 0.025N sodium thiosulfate (Section 7.2.3)

7.2.3 Standard sodium thiosulfate solution, 0.025N. May be purchased commercially or prepared in the laboratory. Standardize against potassium bi-iodate.

7.2.3.1 Weigh approximately 6.2 g of sodium thiosulfate, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5 \text{H}_2\text{O}$, into a 500 mL beaker. Add 0.1 g sodium carbonate, Na_2CO_3 , and dissolve in 400 mL deionized water. Pour into a 1.0 L volumetric flask and dilute to volume with deionized water.

7.2.3.2 Standardization against potassium bi-iodate, $\text{KH}(\text{IO}_3)_2$.

7.2.3.2.1 Prepare 0.00208M potassium bi-iodate by dissolving 0.8123 g $\text{KH}(\text{IO}_3)_2$, previously dried 2 hr at 103-105°C, in distilled water. Pour into a 1.0 L volumetric flask and dilute to volume with deionized water.

7.2.3.2.2 Dissolve approximately 2 g KI, free from iodate, in an erlenmeyer flask with 100 to 150 mL deionized water. Add 1 mL of 6N H_2SO_4 or a few drops of concentrated H_2SO_4 and 20.00 mL of standard bi-iodate solution. Dilute to 200 mL and titrate the liberated iodine with the thiosulfate solution until the yellow color fades to a pale straw color. Then add a couple drops of starch indicator to form a pale blue color and continue the titration with the thiosulfate until the blue color first disappears.

7.2.3.2.3 20.00 mL of 0.00208M $\text{KH}(\text{IO}_3)_2$ requires exactly 20.00 mL of 0.025N sodium thiosulfate. For an calculation of the thiosulfate concentration use the following equation:

$$N (\text{S}_2\text{O}_3^{2-}) = \frac{\text{g KH}(\text{IO}_3)_2}{\text{mL S}_2\text{O}_3^{2-}} \times \frac{1 \text{ mole KH}(\text{IO}_3)_2}{389.9 \text{ g KH}(\text{IO}_3)_2} \times \frac{12 \text{ equiv KH}(\text{IO}_3)_2}{1 \text{ mole KH}(\text{IO}_3)_2} \times \frac{1000 \text{ mL}}{1 \text{ L}}$$

7.2.4 Starch indicator - Dissolve 1.0 gram soluble starch in 100 mL boiling deionized water.

7.2.5 Sulfide working standards - Prepare sulfide working standards using the sulfide stock standard solution in Section 7.2.1. The concentrations of the following standards will depend on the exact concentration of the sulfide stock standard determined in Section 7.2.1.2.5. Correct concentrations of the the standards in the following part of this section and the amount of sulfide in standards used in the colorimetric method in Section 12.2.5 by multiplying by a factor of the concentration determined in Section 7.2.1.2.5 divided by 50 $\mu\text{moles/mL}$.

7.2.5.1 Prepare sulfide working standard A by diluting 1.00 mL of sulfide stock standard to 100.0 mL. This solution contains 0.5 μ mole sulfide/mL, if the concentration of the sulfide stock standard is exactly 0.05M.

7.2.5.2 Prepare sulfide working standard B by diluting 10.00 mL of sulfide stock standard to 100.0 mL. This solution contains 5.0 μ mole sulfide/mL, if the concentration of the sulfide stock standard is exactly 0.05M.

7.3 AVS evolution

7.3.1 Hydrochloric acid 6M - Dilute 500 mL of concentrated hydrochloric acid (sp. gr. 1.19) to 1L with deionized water. Dearthation of this solution as described in Sections 7.1 and 11.4 is most important.

7.3.2 Nitrogen or argon gas, oxygen free, with regulator and flow controller. An oxygen gas scrubber may be required and is available commercially or deoxygenating solutions may be placed in the first flask or gas washing bottle in the analytical train.

7.3.3 Plastic hypodermic syringe, 30 mL, and needle.

7.4 Gravimetric method

7.4.1 Potassium acid phthalate, 0.05M - Dissolve 10.2 g of potassium acid phthalate, $\text{KHC}_8\text{H}_4\text{O}_4$, in deionized water and dilute to 1L.

7.4.2 Silver nitrate, 0.1M - Dissolve 17 g of silver nitrate, AgNO_3 , in deionized water and dilute to 1L. Store in a dark bottle.

7.4.3 Glass fiber filters, 1.2 micron - Rinse with deionized water, then predry filters at 103-105°C.

7.5 Colorimetric method

7.5.1 Sodium hydroxide solution, 1M - Dissolve 40 g sodium hydroxide in 1000 mL deionized water.

7.5.2 Sodium hydroxide solution, 0.5M - Dissolve 20 g sodium hydroxide in 1000 mL deionized water.

7.5.3 Mixed diamine reagent, MDR

7.5.3.1 Component A - Add 660 mL concentrated sulfuric acid to 340 mL of deionized water. After the solution cools, dissolve 2.25 g N-N-dimethy-p-phenylenediamine oxalate in it.

- 7.5.3.2 Component B - Dissolve 5.4 g ferric chloride hexahydrate ($\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$) in 100 mL concentrated hydrochloric acid and dilute to 200 mL with deionized water.
- 7.5.3.3 Mixed diamine reagent, MDR - Mix components A and B.
- 7.5.4 Sulfuric acid solution, 1.0M - Dilute 56 mL concentrated sulfuric acid (H_2SO_4) to 1 L with deionized water.
- 7.6 Ion-selective electrode method
 - 7.6.1 Sodium hydroxide solution - Dissolve 80 g of sodium hydroxide in 700 mL of deionized water with caution. Cool to room temperature.
 - 7.6.2 Sulfide anti-oxidant buffer (SAOB) - To the sodium hydroxide solution in Section 7.6.1 add and dissolve 74.45 g of disodium ethylenediaminetetraacetic acid and 35.23 g of ascorbic acid. Dilute to 1L with deionized water.

8. SAMPLE COLLECTION, PRESERVATION AND STORAGE

- 8.1 Sulfide ion is unstable in the presence of oxygen. Protect sediment samples from exposure to oxygen during sample collection and storage.
- 8.2 During storage sulfide can be formed or lost due to biological activity and sulfide can be lost by volatilization or oxidation. Metal speciation can change as a result of changes in sulfide concentration and as a result of other changes in the sample.
- 8.3 Samples should be collected in wide mouth jars with a minimum of air space above the sediment. If possible, the headspace should be filled with oxygen free nitrogen or argon. The jar lids must have Teflon or polyethylene liners.
- 8.4 Samples should be cooled to 4°C as soon as possible after collection. Samples maintained at 4°C have been found to have no significant loss of AVS for storage periods up to 2 weeks (3). Holding time for samples should not exceed 14 days.

9. CALIBRATION AND STANDARDIZATION

- 9.1 Calibrate the photometer with a minimum of four standards and a blank that cover the expected range of the samples. Prepare a calibration graph relating absorbance to the μmoles of sulfide taken.
- 9.2 Calibrate the sulfide electrode system with a minimum of three standards that cover the expected range of the samples. Standards must be made up in SAOB diluted 1+1 with deionized water. Follow the manufacturer's instructions for use of the electrode.

- 9.3 Overall sulfide recovery is determined by analysis of a known amount of sodium sulfide standard added to deionized water from which the sulfide is liberated in the analysis train (LFB). Recoveries of 95% ± 10% are expected.

10. QUALITY CONTROL

10.1 Each laboratory using this method is required to operate a formal quality control (QC) program. The minimum requirement of this program consists of an initial demonstration of laboratory capability, and the analysis of laboratory reagent blanks, fortified blanks and fortified samples as a continuing check on performance. The laboratory is required to maintain performance records that define the quality of data thus generated.

10.2 INITIAL DEMONSTRATION OF PERFORMANCE

10.2.1 The initial demonstration of performance is used to characterize instrument performance, method detection limits, and linear calibration ranges.

10.2.2 Method detection limit (MDL) - The method detection limit should be established for the analyte, using deionized water (blank) fortified at a concentration two to five times the estimated detection limit (10). To determine MDL values, take seven replicate aliquots of the fortified reagent water and process through the entire analytical method. Perform all calculations and report the concentration values in the appropriate units. Calculate the MDL as follows:

$$\text{MDL} = t \times s$$

where, t = students' t value for a 99% confidence level and a standard deviation estimate with $n-1$ degrees of freedom ($t = 3.14$ for seven replicates), and

s = standard deviation of the replicate analyses.

Method detection limits should be determined every six months or whenever a significant change in background or instrument response is expected.

10.2.3 Linear calibration ranges - The upper limit of the linear calibration range should be established by determining the signal responses from a minimum of four different concentration standards covering the expected range, one of which is close to the upper limit. The linear calibration range that may be used for the analysis of samples should be judged by the analyst from resulting data. Linear calibration ranges should be determined every six months or whenever a significant change in instrument response may be expected.

10.3 ASSESSING LABORATORY PERFORMANCE - REAGENT AND FORTIFIED BLANKS

10.3.1 Laboratory reagent blank (LRB) - The laboratory must analyze at least one laboratory reagent blank (Section 3.4) with each set of samples. Reagent blank data are used to assess contamination from the laboratory environment and reagents. If an analyte value in the reagent blank exceeds its determined MDL, then laboratory or reagent contamination should be suspected. Any determined source of contamination should be corrected and the samples reanalyzed.

10.3.2 Laboratory fortified blank (LFB) - The laboratory must analyze at least one laboratory fortified blank (Section 3.7) with each set of 20 samples. Calculate accuracy as percent recovery. If the recovery of the analyte falls outside the control limits (Section 10.3.3), the analyte is judged to be out of control, and the source of the problem should be identified and resolved before continuing analyses.

10.3.3 Until sufficient data become available from within their own laboratory (usually a minimum of twenty to thirty analyses), the laboratory should assess laboratory performance against recovery limits of 85-105%. When sufficient internal performance data becomes available, develop control limits from the mean recovery (\bar{x}) and the standard deviation (s) of the mean recovery. These data are used to establish upper and lower control limits as follows:

$$\text{UPPER CONTROL LIMIT} = \bar{x} + 3s$$

$$\text{LOWER CONTROL LIMIT} = \bar{x} - 3s$$

After each five to ten new recovery measurements, new control limits should be calculated using only the most recent twenty to thirty data points.

10.4 ASSESSING ANALYTE RECOVERY - LABORATORY FORTIFIED SAMPLE MATRIX

10.4.1 The laboratory must fortify a minimum of 10% of the routine samples or one fortified sample per set of 20 samples, whichever is greater. At least one sample from each source should be fortified. Ideally, the concentration should at least double the background concentration. Over time, samples from all routine sample sources should be fortified.

10.4.2 Calculate the percent recovery for the analyte, corrected for background concentrations measured in the unfortified sample, and compare these values to the control limits established in Section 10.3.3 for the analyses of LFBs. Spike recovery calculations are not required if the spike concentration is less than 10%

of the sample background concentration. Percent recovery may be calculated in units appropriate to the matrix, using the following equation:

$$R = \frac{(C_f - C_b)}{S} \times 100$$

where

R = percent recovery,

C_f = fortified sample concentration,

C_b = sample background concentration, and

S = concentration equivalent of the fortified sample.

10.4.3 If the recovery of the analyte in the fortified sample falls outside the designated range, and the laboratory performance on the LFB for the analyte is shown to be in control (Section 10.3) the recovery problem encountered with the fortified sample is judged to be matrix related, not system related.

11. GENERATION OF H₂S

11.1 Assemble glassware according to the detection method to be used. The setup in Figure 1 should be followed as a general guide. In all cases a flask or gas washing bottle containing a deoxygenating solution may be placed in the sample train between the nitrogen or argon tank and the first flask. Glassware is specified in Section 6.1.1. It is recommended that nitrogen or argon be controlled by a flow controller, but an equivalent flow rate may be regulated by a clamp and bubble rate determined. In all cases the glassware will minimally consist of a H₂S generating flask and a series of traps.

11.1.1 Gravimetric method - The first flask contains the sediment sample or standard. The second flask contains 175-200 mL of potassium hydrogen phthalate reagent 7.4.1 as an HCl trap. The third and fourth flasks contain 175-200 mL of silver nitrate reagent 7.4.2. If glassware specified in Section 6.1.1.1 is used, the second flask is a gas washing bottle and the third and fourth flasks are impingers.

11.1.2 Colorimetric method - The first flask contains the sediment sample or standard. The second and third flask contain an absorbant of 80 mL 0.5M NaOH reagent 7.5.2. If glassware specified in Section 6.1.1.1 is used, the second and third flasks are impingers.

- 11.1.3 Ion-selective electrode method - The first flask contains the sediment sample or standard. The second and third flask contain an absorbant of 50 mL SAOB reagent 7.6.2 and 30 mL deionized water. If glassware specified in Section 6.1.1.1 is used, the second and third flasks are impingers.
- 11.2 One hundred milliliters (100 mL) of deionized water and a magnetic stirring bar are added to the flask that will contain the sediment. The total volume of deionized water plus water contained in the wet sediment sample should not exceed 120 mL to minimize differences in acid concentration among samples. For the computation of the volume of water contained in the wet sediment, see Section 13.3. The traps are filled and deaerated by bubbling nitrogen or argon for 10 minutes at a flowrate of 100 cm³/min. Reduce flow to 40 cm³/min.
- 11.3 Weigh approximately 10 g of wet sediment on an analytical balance. Record weight to the nearest milligram. If AVS concentration is high, a smaller amount of sediment may be required; use of sediment samples smaller than 1-2 grams is not recommended due to sulfide oxidation and sample heterogeneity. Use of large sediment samples is not recommended because significant amounts of acid may be neutralized. Place sediment in the standard taper round bottom flask or the Erlenmeyer flask fitted with the thistle tube or separatory funnel. Parafilm has been found to be free of sulfide (4). Weigh samples on 2 x 2 inch pieces of parafilm and introduce the parafilm and sample to the flask. Rinsing the sample into the flask is not recommended. Purge the sample for 10 minutes with nitrogen or argon at a flowrate of 40 cm³/min. Stop the flow of gas.
- 11.4 Using a 30 mL syringe, inject 20 mL of 6M HCl, which has been bubbled with nitrogen or argon gas for 30 minutes, into the reactor through the septum. If the apparatus described in Section 6.1.1.1 is used, add the HCl from the thistle tube or the separatory funnel. Bubble nitrogen or argon through the sample for 1 hour at a flowrate of 20 cm³/min and magnetically stir the sample at the same time.
- 11.5 Analyze sulfide contained in sulfide trap by the appropriate analytical procedure in Section 12.

12. ANALYSIS OF SULFIDE

12.1 Gravimetric method

12.1.1 Insure that the final trap, the second silver nitrate trap, contains no precipitate.

12.1.2 Filter the silver sulfide contained in the first sulfide trap through a preweighed 1.2 micron filter. Rinse filter with deionized water. Dry at 103-105°C and weigh.

12.1.3 Calculate the amount of silver sulfide as the difference between the weight of silver sulfide and the filter and the weight of the predried filter.

12.1.4 Calculate the amount of sulfide in the sample:

$$\text{Sulfide in wet sediment } (\mu\text{moles}) = \frac{\text{g Ag}_2\text{S}}{247.8} \times 10^6$$

12.2 Colorimetric method

12.2.1 If the AVS concentration is low so that the sulfide contained in the tube trap is less than 15 μmoles , add 10 mL of the mixed diamine reagent (MDR) directly to the NaOH solution in each trap tube to develop the color. Transfer this solution to a 100 mL volumetric flask and dilute to the mark with deionized water. If the sulfide contained in the NaOH in the tube trap exceeds 18 μmoles , transfer the NaOH in each tube trap to a 100 mL volumetric flask. Rinse the trap with deaerated 0.5M NaOH and dilute to volume with NaOH. An appropriate volume aliquot of this solution is used for the analysis. In this case, the aliquot is transferred to a 100 mL volumetric flask, sufficient 0.5M NaOH is added so that the total volume is 80 mL, 10 mL MDR is added, and the solution is diluted to 100 mL with deionized water. Use of sediment samples smaller than 1-2 grams is not recommended due to sulfide oxidation and sample heterogeneity.

12.2.2 After 30 minutes, but before two hours have elapsed, measure the absorbance of light at 670 nm using a half-inch diameter or 1 cm rectangular spectrophotometer cell.

12.2.3 If the absorbance of the sample is greater than 0.6, dilute 10-fold with 1.0M H_2SO_4 and compare to the high range calibration curve.

12.2.4 Normally, the sulfide concentration in second trap tube is close to the blank value in this procedure and is not significant in calculating the concentration of sulfide. If a significant color is developed, the flow rate and amount of sulfide in the standard or sediment should be checked.

12.2.5 Preparation of calibration curve - The indicated amounts of sulfide are based on a 0.05M concentration of the sulfide stock standard solution. The procedure indicated in Section 7.2.5 should be used to calculate the exact amount of sulfide in each of the standards.

12.2.5.1 Low range calibration curve - 0.0 - 2.5 $\mu\text{moles S}^{2-}$ (0.0 - 80 $\mu\text{g S}^{2-}$)

Add 80 mL 0.5 N sodium hydroxide to each of a series of 100 mL of flasks and add 0.00, 1.00, 2.00, 3.00, 4.00, and 5.00 mL of sulfide working standard A to these flasks. These samples contain 0.00,

0.50, 1.00, 1.50, 2.00, and 2.50 $\mu\text{moles S}^{2-}$, respectively. Add 10.0 mL of MDR to each and dilute to 100.00 mL with deionized water. After 30 minutes, measure the absorbance at 670 nm.

12.2.5.2 High range calibration curve - 0.0 - 20.0 $\mu\text{moles S}^{2-}$
(0.0 - 640 $\mu\text{g S}^{2-}$)

Add 80 mL 0.5M sodium hydroxide in 100 mL flasks and add 0.00, 1.00, 2.00, 3.00 and 4.00 mL of sulfide working standard B to these flasks. These samples contain 0.0, 5.00, 10.00, 15.00, and 20.00 $\mu\text{moles S}^{2-}$, respectively. Add 10.0 mL of MDR and dilute to 100.00 mL with deionized water. After 30 minutes, dilute the solution 10-fold with 1.0M H_2SO_4 , and measure the absorbance at 670 nm.

12.2.6 Calculate the amount of sulfide (μmoles) in the sample from the calibration curve. If the total volume of NaOH in the trap was not used in the analysis, account for the portion tested.

12.3 Ion-selective electrode method

12.3.1 Calibrate the sulfide electrode and meter according to manufacturer's recommendations, using sulfide standards prepared in SAOB reagent 7.6.2 diluted 1:1 with deionized water.

12.3.2 Transfer the contents of each sulfide trap into a 100-mL volumetric flask. Rinse the trap with deionized water, adding the rinses to the volumetric flask. Dilute to volume with deionized water.

12.3.3 Pour contents of volumetric flask into a 150-mL beaker, add a stirring bar and place on stirrer. Begin stirring with minimum agitation to avoid entrainment of air into the solution and minimize oxidation of the sample during the measurement.

12.3.4 Rinse sulfide and reference electrodes into waste container and blot dry with absorbent tissue. Immerse electrodes in sample solution.

12.3.5 Allow electrode response to stabilize (8-10 minutes), then take measurement of sulfide concentration. Depending on the meter used, the reading may be directly in concentration units if the meter is in the concentration mode and a 2-point calibration has been performed. If the readings are in millivolts, convert millivolts to concentration using the calibration curve obtained from standard solutions.

12.3.6 Calculate the amount of sulfide (μmoles) in the sample.

13. CALCULATION OF AVS CONCENTRATION IN SEDIMENTS

- 13.1 The sediment dry weight/wet weight ratio (R) must be determined separately. Acid volatile sulfide can be oxidized or altered to non-volatile forms during drying.
- 13.2 Transfer an aliquot of the sediment to a tared 100-mL tared evaporating dish. Weigh the dish plus the wet sediment. Calculate the wet weight of the sample. Dry the sediment at 103-105°C and weigh. Calculate the dry weight of sediment.
- 13.3 Determine the ratio of dry weight to wet weight for the sediment sample:

$$R = \frac{W_d}{W_w}$$

where R = ratio of dry weight to wet weight,

W_d = dry weight of sediment sample (g), and

W_w = wet weight of sediment sample (g).

Also, the weight of water, W_{water} , taken in a sample for AVS analysis can be calculated. If the weight of the wet sediment sample taken for the AVS analysis is W_{s+w} , the weight of water contained in the sediment sample would be

$$W_{\text{water}} = W_{s+w} - (R \times W_{s+w})$$

The volume of water in the sample equals the weight of water, assuming the density is near unity.

- 13.4 Compute the sulfide concentration per gram dry weight of sediment:

$$\text{AVS } (\mu\text{moles/g}) = \frac{S}{R \times W_w}$$

where S = the amount of AVS in sediment (μmoles) from Section 12.1.4,

12.2.6, or 12.3.6, as appropriate,

R = ratio of dry weight to wet weight from Section 13.3, and

W_w = wet weight of sediment (g) taken for AVS analysis.

- 13.5 The QC data obtained during the analysis provides an indication of the quality of the sample data and should be provided with the sample results.

14. DETERMINATION OF SIMULTANEOUSLY EXTRACTED METALS (SEM)

- 14.1 After the generation of sulfide has been completed, filter the sediment suspension remaining in the H_2S generation flask (Section 11.4) through a 0.2 μ membrane filter

resistant to attack by acid. The filtering apparatus should be soaked in 0.1M HNO₃, then rinsed with deionized water prior to use.

- 14.2 Transfer the filtrate to a 250-mL volumetric flask. Rinse the filtering flask with distilled water, adding the rinses to the volumetric flask. Dilute to volume with deionized water. The volumetric flasks should be soaked in 0.1M HNO₃, then rinsed with deionized water prior to use. Samples should be analyzed within 2 weeks.
- 14.3 Determine the concentrations of sulfide binding metals of interest and those which, on a molar basis, are present at more than 1 percent of the AVS concentration. Do not include iron and manganese whose sulfides are less stable than are the sulfides of many trace metals. Metals which may typically be included in SEM are cadmium, copper, lead, mercury, nickel and zinc. In addition, antimony, bismuth and chromium, among others, form insoluble sulfides. If significant concentrations of these or other metals forming insoluble sulfides are present, their concentrations should be taken into account in the computation of SEM. However, if these or other metals which are not divalent are present in significant concentrations, the computation in Section 14.5 must be modified to account for the stoichiometry. Metal concentrations may be determined by atomic absorption, inductive coupled plasma spectrometric, or another approved method (6, 7). Calibration may be by the method of standard additions or by a calibration curve. If a calibration curve is used, matrix match standards to samples by including 20 mL of 6M HCl per 100 mL for each of the calibration standards. Convert µg/L concentration values to µmoles/L. Multiply the µmoles/L by the solution volume to obtain the µmoles of metal.
- 14.4 Report the concentrations of each of the metals in the sediment on a µmole per gram dry sediment (µmole/g) basis.
- 14.5 Calculate the ratio of SEM to AVS:

$$\frac{SEM}{AVS} = \frac{\sum [metal]}{AVS}$$

where SEM is the sum of the concentrations of metals, $\Sigma [metal]$, for the metals (e.g., cadmium, copper, lead, mercury, nickel and zinc) in Section 14.4 and AVS is the acid volatile sulfide concentration determined in Section 13.4.

Both SEM and AVS are expressed on a µmole per gram dry sediment (µmol/g) basis. Because metals present in the pore will be included in the analysis, the ratio could be less than that if correction were made for this contribution. This will lead to a conservative estimation of potential bioavailability (1).

Ammonia

USEPA Method 350.2/350.3

METHOD #: 350.2 Approved for NPDES (Editorial Revision 1974)

TITLE: Nitrogen, Ammonia (Colorimetric, Titrimetric, Potentiometric Distillation Procedure)

ANALYTE: CAS # Nitrogen
 7727-37-9, N
 CAS # Ammonium 7664-41-7, NH₃

INSTRUMENTATION: Titration, Spectrophotometer

STORET No. Total 00610
 Dissolved 00608

1.0 Scope and Application

- 1.1 This distillation method covers the determination of ammonia-nitrogen exclusive of total Kjeldahl nitrogen, in drinking, surface and saline waters, domestic and industrial wastes. It is the method of choice where economics and sample load do not warrant the use of automated equipment.
- 1.2 The method covers the range from about 0.05 to 1.0 mg NH₃-N/L for the colorimetric procedure, from 1.0 to 25 mg/L for the titrimetric procedure, and from 0.05 to 1400 mg/L for the electrode method.
- 1.3 This method is described for macro glassware; however, microdistillation equipment may also be used.

2.0 Summary of Method

- 2.1 The sample is buffered at a pH of 9.5 with a borate buffer in order to decrease hydrolysis of cyanates and organic nitrogen compounds, and is then distilled into a solution of boric acid. The ammonia in the distillate can be determined colorimetrically by nesslerization, titrimetrically with standard sulfuric acid with the use of a mixed indicator, or potentiometrically by the ammonia electrode. The choice between the first two procedures depends on the concentration of the ammonia.

3.0 Sample Handling and Preservation

- 3.1 Samples may be preserved with 2 mL of conc. H₂SO₄ per liter and stored at 4°C.

4.0 Interferences

- 4.1 A number of aromatic and aliphatic amines, as well as other compounds, both organic and inorganic, will cause turbidity upon the addition of Nessler reagent, so direct nesslerization (i.e., without distillation), has been discarded as an official method.
- 4.2 Cyanate, which may be encountered in certain industrial emulents, will hydrolyze to some extent even at the pH of 9.5 at which distillation is carried

out. Volatile alkaline compounds, such as certain ketones, aldehydes, and alcohols, may cause an off-color upon nesslerization in the distillation method. Some of these, such as formaldehyde, may be eliminated by boiling off at a low pH (approximately 2 to 3) prior to distillation and nesslerization.

- 4.3 Residual chlorine must also be removed by pretreatment of the sample with sodium thiosulfate before distillation.

5.0 Apparatus

- 5.1 An all-glass distilling apparatus with an 800-1000 mL flask.
- 5.2 Spectrophotometer or filter photometer for use at 425 nm and providing a light path of 1 cm or more.
- 5.3 Nessler tubes: Matched Nessler tubes (APHA Standard) about 300 mm long, 17 mm inside diameter, and marked at 225 mm \pm 1.5 mm inside measurement from bottom.
- 5.4 Erlenmeyer flasks: The distillate is collected in 500 mL glass-stoppered flasks. These flasks should be marked at the 350 and the 500 mL volumes. With such marking, it is not necessary to transfer the distillate to volumetric flasks.

6.0 Reagents

- 6.1 Distilled water should be free of ammonia. Such water is best prepared by passage through an ion exchange column containing a strongly acidic cation exchange resin mixed with a strongly basic anion exchange resin. Regeneration of the column should be carried out according to the manufacturer's instructions.
- NOTE 1:** All solutions must be made with ammonia-free water.
- 6.2 Ammonium chloride, stock solution: 1.0 mL = 1.0 mg NH₃-N. Dissolve 3.819 g NH₄Cl in distilled water and bring to volume in a 1 liter volumetric flask.
- 6.3 Ammonium chloride, standard solution: 1.0 mL = 0.01 mg. Dilute 10.0 mL of stock solution (6.2) to 1 liter in a volumetric flask.
- 6.4 Boric acid solution (20 g/L): Dissolve 20 g H₃BO₃ in distilled water and dilute to 1 liter.
- 6.5 Mixed indicator: Mix 2 volumes of 0.2% methyl red in 95% ethyl alcohol with 1 volume of 0.2% methylene blue in 95% ethyl alcohol. This solution should be prepared fresh every 30 days.
- NOTE 2:** Specially denatured ethyl alcohol conforming to Formula 3A or 30 of the U.S. Bureau of Internal Revenue may be substituted for 95% ethanol.
- 6.6 Nessler reagent: Dissolve 100 g of mercuric iodide and 70 g of potassium iodide in a small amount of water. Add this mixture slowly, with stirring, to a cooled solution of 160 g of NaOH in 500 mL of water. Dilute the mixture to 1 liter. If this reagent is stored in a Pyrex bottle out of direct sunlight, it will remain stable for a period of up to 1 year.
- NOTE 3:** This reagent should give the characteristic color with ammonia within 10 minutes after addition, and should not produce a precipitate with small amounts of ammonia (0.04 mg in a 50 mL volume).
- 6.7 Borate buffer: Add 88 mL of 0.1 N NaOH solution to 500 mL of 0.025 M sodium tetraborate solution (5.0 g anhydrous Na₂B₄O₇, or 9.5 g Na₂B₄O₇•10H₂O per liter) and dilute to 1 liter.
- 6.8 Sulfuric acid, standard solution: (0.02 N, 1 mL = 0.28 mg NH₃-N). Prepare a

stock solution of approximately 0.1 N acid by diluting 3 mL of conc. H_2SO_4 (sp. gr. 1.84) to 1 liter with CO_2 -free distilled water. Dilute 200 mL of this solution to 1 liter with CO_2 -free distilled water.

NOTE 4: An alternate and perhaps preferable method is to standardize the approximately 0.1 N H_2SO_4 solution against a 0.100 N Na_2CO_3 solution. By proper dilution the 0.02 N acid can then be prepared.

6.8.1 Standardize the approximately 0.02 N acid against 0.0200 N Na_2CO_3 solution. This last solution is prepared by dissolving 1.060 g anhydrous Na_2CO_3 , oven-dried at 140°C , and diluting to 1000 mL with CO_2 -free distilled water.

6.9 Sodium hydroxide 1 N: Dissolve 40 g NaOH in ammonia-free water and dilute to 1 liter.

6.10 Dechlorinating reagents: A number of dechlorinating reagents may be used to remove residual chlorine prior to distillation. These include:

- a. Sodium thiosulfate (1/70 N): Dissolve 3.5 g $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ in distilled water and dilute to 1 liter. One mL of this solution will remove 1 mg/L of residual chlorine in 500 mL of sample.
- b. Sodium arsenite (1/70 N): Dissolve 1.0 g NaAsO_2 in distilled water and dilute to 1 liter.

7.0 Procedure

7.1 Preparation of equipment: Add 500 mL of distilled water to an 800 mL Kjeldahl flask. The addition of boiling chips which have been previously treated with dilute NaOH will prevent bumping. Steam out the distillation apparatus until the distillate shows no trace of ammonia with Nessler reagent.

7.2 Sample preparation: Remove the residual chlorine in the sample by adding dechlorinating agent equivalent to the chlorine residual. To 400 mL of sample add 1 N NaOH (6.9), until the pH is 9.5, checking the pH during addition with a pH meter or by use of a short range pH paper.

7.3 Distillation: Transfer the sample, the pH of which has been adjusted to 9.5, to an 800 mL Kjeldahl flask and add 25 mL of the borate buffer (6.7). Distill 300 mL at the rate of 6-10 mL/min. into 50 mL of 2% boric acid (6.4) contained in a 500 mL Erlenmeyer flask.

NOTE 5: The condenser tip or an extension of the condenser tip must extend below the level of the boric acid solution. Dilute the distillate to 500 mL with distilled water and nesslerize an aliquot to obtain an approximate value of the ammonia-nitrogen concentration. For concentrations above 1 mg/L the ammonia should be determined titrimetrically. For concentrations below this value it is determined colorimetrically. The electrode method may also be used.

7.4 Determination of ammonia in distillate: Determine the ammonia content of the distillate titrimetrically, colorimetrically or potentiometrically as described below.

7.4.1 Titrimetric determination: Add 3 drops of the mixed indicator to the distillate and titrate the ammonia with the 0.02 N H_2SO_4 , matching the end point against a blank containing the same volume of distilled water and H_3BO_3 solution.

7.4.2 Colorimetric determination: Prepare a series of Nessler tube standards as follows:

mL of Standard	
1.0 mL = mg NH ₃ -N	mg NH ₃ -N/50.0 mL
0.0	0.0
0.5	0.005
1.0	0.01
2.0	0.02
3.0	0.03
4.0	0.04
5.0	0.05
8.0	0.08
10.0	0.10

Dilute each tube to 50 mL with distilled water, add 2.0 mL of Nessler reagent (6.6) and mix. After 20 minutes read the absorbance at 425 nm against the blank. From the values obtained plot absorbance vs. mg NH₃-N for the standard curve. Determine the ammonia in the distillate by nesslerizing 50 mL or an aliquot diluted to 50 mL and reading the absorbance at 425 nm as described above for the standards. Ammonia-nitrogen content is read from the standard curve.

7.4.3 Potentiometric determination: Consult the method entitled Nitrogen, Ammonia: Selective Ion Electrode Method (Method 350.3) in this manual.

7.5 It is not imperative that all standards be distilled in the same manner as the samples. It is recommended that at least two standards (a high and low) be distilled and compared to similar values on the curve to insure that the distillation technique is reliable. If distilled standards do not agree with undistilled standards the operator should find the cause of the apparent error before proceeding.

8.0 Calculations

8.1 Titrimetric

$$\text{mg/L NH}_3 - \text{N} = \frac{A \times 0.28 \times 1,000}{S}$$

where:

A = mL 0.02 N H₂SO₄ used.

S = mL sample.

8.2 Spectrophotometric

$$\text{mg/L NH}_3 - \text{N} = \frac{\text{A} \times 1,000}{\text{D}} \times \frac{\text{B}}{\text{C}}$$

where:

A = mg NH₃-N read from standard curve.

B = mL total distillate collected, including boric acid and dilution.

C = mL distillate taken for nesslerization.

D = mL of original sample taken.

8.3 Potentiometric

$$\text{mg/L NH}_3 - \text{N} = \frac{500}{\text{D}} \times \text{A}$$

where:

A = mg NH₃-N/L from electrode method standard curve.

D = mL of original sample taken.

9. Precision and Accuracy

9.1 Twenty-four analysts in sixteen laboratories analyzed natural water samples containing exact increments of an ammonium salt, with the following results:

Increment as Nitrogen, Ammonia mg N/liter	Precision as Standard Deviation mg N/liter	Accuracy as Bias %	Bias mg N/liter
0.21	0.122	-5.54	-0.01
0.26	0.070	-18.12	-0.05
1.71	0.244	+0.46	+0.01
1.92	0.279	-2.01	-0.04

Dissolved 00608

1.0 Scope and Application

- 1.1 This method is applicable to the measurement of ammonia-nitrogen in drinking, surface and saline waters, domestic and industrial wastes.
- 1.2 This method covers the range from 0.03 to 1400 mg NH₃-N/L. Color and turbidity have no effect on the measurements, thus, distillation may not be necessary.

2.0 Summary of Method

- 2.1 The ammonia is determined potentiometrically using an ion selective ammonia electrode and a pH meter having an expanded millivolt scale or a specific ion meter.
- 2.2 The ammonia electrode uses a hydrophobic gas-permeable membrane to separate the sample solution from an ammonium chloride internal solution. Ammonia in the sample diffuses through the membrane and alters the pH of the internal solution, which is sensed by a pH electrode. The constant level of chloride in the internal solution is sensed by a chloride selective ion electrode which acts as the reference electrode.

3.0 Sample Handling and Preservation

- 3.1 Samples may be preserved with 2 mL of conc. H₂SO₄ per liter and stored at 4°C.

4.0 Interferences

- 4.1 Volatile amines act as a positive interference.
- 4.2 Mercury interferes by forming a strong complex with ammonia. Thus the samples cannot be preserved with mercuric chloride.

5.0 Apparatus

- 5.1 Electrometer (pH meter) with expanded mV scale or a specific ion meter.
- 5.2 Ammonia selective electrode, such as Orion Model 95-10 or EIL Model 8002-2.
- 5.3 Magnetic stirrer, thermally insulated, and Teflon-Coated stirring bar.

6.0 Reagents

- 6.1 Distilled water: Special precautions must be taken to insure that the distilled water is free of ammonia. This is accomplished by passing distilled water through an ion exchange column containing a strongly acidic cation exchange resin mixed with a strongly basic anion exchange resin.
- 6.2 Sodium hydroxide, 10N: Dissolve 400 g of sodium hydroxide in 800 mL of distilled water. Cool and dilute to 1 liter with distilled water (6.1).
- 6.3 Ammonium chloride, stock solution: 1.0 mL = 1.0 mg NH₃-N. Dissolve 3.819 g NH₄Cl in water and bring to volume in a 1 liter volumetric flask using distilled water (6.1).
- 6.4 Ammonium chloride, standard solution: 1.0 mL = 0.01 mg NH₃-N. Dilute 10.0 mL of the stock solution (6. 3) to 1 liter with distilled water (6.1) in a volumetric flask.
NOTE 1: When analyzing saline waters, standards must be made up in synthetic ocean water (SOW); found in Nitrogen, Ammonia: Colorimetric, Automated Phenate Method (350. 1).

7.0 Procedure

- 7.1 Preparation of standards: Prepare a series of standard solutions covering the concentration range of the samples by diluting either the stock or standard solutions of ammonium chloride.
- 7.2 Calibration of electrometer: Place 100 mL of each standard solution in clean 150 mL beakers. Immerse electrode into standard of lowest concentration and add 1 mL of 10N sodium hydroxide solution while mixing. Keep electrode in the solution until a stable reading is obtained.
NOTE 2: The pH of the solution after the addition of NaOH must be above 11. Caution: Sodium hydroxide must not be added prior to electrode immersion, for ammonia may be lost from a basic solution.
- 7.3 Repeat this procedure with the remaining standards, going from lowest to highest concentration. Using semilogarithmic graph paper, plot the concentration of ammonia in mg NH₃-N/L on the log axis vs. the electrode potential developed in the standard on the linear axis, starting with the lowest concentration at the bottom of the scale.
- 7.4 Calibration of a specific ion meter: Follow the directions of the manufacturer for the operation of the instrument.
- 7.5 Sample measurement: Follow the procedure in (7.2) for 100 mL of sample in 150 mL beakers. Record the stabilized potential of each unknown sample and convert the potential reading to the ammonia concentration using the standard curve. If a specific ion meter is used, read the ammonia level directly in mg NH₃-N/L.

8.0 Precision and Accuracy

- 8.1 In a single laboratory (EMSL), using surface water samples at concentrations of 1.00, 0.77, 0.19, and 0.13 mg NH₃-N/L, standard deviations were ± 0.038, ± 0.017, ± 0.007, and ± 0.003, respectively.
- 8.2 In a single laboratory (EMSL), using surface water samples at concentrations of 0.19 and 0.13 mg NH₃-N/L, recoveries were 96% and 91%, respectively.

No. L-27

Grain Size (solid)

ASTM D422

Standard Test Method for Particle-Size Analysis of Soils¹

This standard is issued under the fixed designation D 422; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the quantitative determination of the distribution of particle sizes in soils. The distribution of particle sizes larger than 75 μm (retained on the No. 200 sieve) is determined by sieving, while the distribution of particle sizes smaller than 75 μm is determined by a sedimentation process, using a hydrometer to secure the necessary data (Note 1 and Note 2).

NOTE 1—Separation may be made on the No. 4 (4.75-mm), No. 40 (425-μm), or No. 200 (75-μm) sieve instead of the No. 10. For whatever sieve used, the size shall be indicated in the report.

NOTE 2—Two types of dispersion devices are provided: (1) a high-speed mechanical stirrer, and (2) air dispersion. Extensive investigations indicate that air-dispersion devices produce a more positive dispersion of plastic soils below the 20-μm size and appreciably less degradation on all sizes when used with sandy soils. Because of the definite advantages favoring air dispersion, its use is recommended. The results from the two types of devices differ in magnitude, depending upon soil type, leading to marked differences in particle size distribution, especially for sizes finer than 20 μm.

2. Referenced Documents

2.1 ASTM Standards:

D 421 Practice for Dry Preparation of Soil Samples for Particle-Size Analysis and Determination of Soil Constants²

E 11 Specification for Wire-Cloth Sieves for Testing Purposes³

E 100 Specification for ASTM Hydrometers⁴

3. Apparatus

3.1 *Balances*—A balance sensitive to 0.01 g for weighing the material passing a No. 10 (2.00-mm) sieve, and a balance sensitive to 0.1 % of the mass of the sample to be weighed for weighing the material retained on a No. 10 sieve.

3.2 *Stirring Apparatus*—Either apparatus A or B may be used.

3.2.1 Apparatus A shall consist of a mechanically operated

stirring device in which a suitably mounted electric motor turns a vertical shaft at a speed of not less than 10 000 rpm without load. The shaft shall be equipped with a replaceable stirring paddle made of metal, plastic, or hard rubber, as shown in Fig. 1. The shaft shall be of such length that the stirring paddle will operate not less than $\frac{3}{4}$ in. (19.0 mm) nor more than 1½ in. (38.1 mm) above the bottom of the dispersion cup. A special dispersion cup conforming to either of the designs shown in Fig. 2 shall be provided to hold the sample while it is being dispersed.

3.2.2 Apparatus B shall consist of an air-jet dispersion cup⁵ (Note 3) conforming to the general details shown in Fig. 3 (Note 4 and Note 5).

NOTE 3—The amount of air required by an air-jet dispersion cup is of the order of 2 ft³/min; some small air compressors are not capable of supplying sufficient air to operate a cup.

NOTE 4—Another air-type dispersion device, known as a dispersion tube, developed by Chu and Davidson at Iowa State College, has been shown to give results equivalent to those secured by the air-jet dispersion cups. When it is used, soaking of the sample can be done in the sedimentation cylinder, thus eliminating the need for transferring the slurry. When the air-dispersion tube is used, it shall be so indicated in the report.

NOTE 5—Water may condense in air lines when not in use. This water must be removed, either by using a water trap on the air line, or by blowing the water out of the line before using any of the air for dispersion purposes.

3.3 *Hydrometer*—An ASTM hydrometer, graduated to read in either specific gravity of the suspension or grams per litre of suspension, and conforming to the requirements for hydrometers 151H or 152H in Specifications E 100. Dimensions of both hydrometers are the same, the scale being the only item of difference.

3.4 *Sedimentation Cylinder*—A glass cylinder essentially 18 in. (457 mm) in height and 2½ in. (63.5 mm) in diameter, and marked for a volume of 1000 mL. The inside diameter shall be such that the 1000-mL mark is 36 ± 2 cm from the bottom on the inside.

3.5 *Thermometer*—A thermometer accurate to 1°F (0.5°C).

3.6 *Sieves*—A series of sieves, of square-mesh woven-wire cloth, conforming to the requirements of Specification E 11. A full set of sieves includes the following (Note 6):

⁵ Detailed working drawings for this cup are available at a nominal cost from the American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428. Order Adjunct No. ADJD0422.

¹ This test method is under the jurisdiction of ASTM Committee D-18 on Soil and Rock and is the direct responsibility of Subcommittee D18.03 on Texture, Plasticity, and Density Characteristics of Soils.

No. 8 (2.36-mm)	

3.7 *Water Bath or Constant-Temperature Room*—A water bath or constant-temperature room for maintaining the soil suspension at a constant temperature during the hydrometer analysis. A satisfactory water tank is an insulated tank that maintains the temperature of the suspension at a convenient constant temperature at or near 68°F (20°C). Such a device is illustrated in Fig. 4. In cases where the work is performed in a room at an automatically controlled constant temperature, the water bath is not necessary.

3.8 *Beaker*—A beaker of 250-mL capacity.

3.9 *Timing Device*—A watch or clock with a second hand.

4. Dispersing Agent

4.1 A solution of sodium hexametaphosphate (sometimes called sodium metaphosphate) shall be used in distilled or demineralized water, at the rate of 40 g of sodium hexametaphosphate/litre of solution (Note 7).

NOTE 7—Solutions of this salt, if acidic, slowly revert or hydrolyze back to the orthophosphate form with a resultant decrease in dispersive action. Solutions should be prepared frequently (at least once a month) or adjusted to pH of 8 or 9 by means of sodium carbonate. Bottles containing solutions should have the date of preparation marked on them.

4.2 All water used shall be either distilled or demineralized water. The water for a hydrometer test shall be brought to the temperature that is expected to prevail during the hydrometer test. For example, if the sedimentation cylinder is to be placed in the water bath, the distilled or demineralized water to be used shall be brought to the temperature of the controlled water bath; or, if the sedimentation cylinder is used in a room with controlled temperature, the water for the test shall be at the temperature of the room. The basic temperature for the hydrometer test is 68°F (20°C). Small variations of temperature do not introduce differences that are of practical significance and do not prevent the use of corrections derived as prescribed.

5. Test Sample

5.1 Prepare the test sample for mechanical analysis as outlined in Practice D 421. During the preparation procedure

FIG. 3 Air-Jet Dispersion Cups of Apparatus B

		Metric Equivalents					
in.		7/8	1	3	6 1/4	14	37
mm		22.2	25.4	76.2	158.2	356	940

FIG. 4 Insulated Water Bath

the sample is divided into two portions. One portion contains only particles retained on the No. 10 (2.00-mm) sieve while the other portion contains only particles passing the No. 10 sieve. The mass of air-dried soil selected for purpose of tests, as prescribed in Practice D 421, shall be sufficient to yield quantities for mechanical analysis as follows:

5.1.1 The size of the portion retained on the No. 10 sieve shall depend on the maximum size of particle, according to the following schedule:

Nominal Diameter of Largest Particles, in. (mm)	Approximate Minimum Mass of Portion, g
3/8 (9.5)	500
3/4 (19.0)	1000
1 (25.4)	2000
1 1/2 (38.1)	3000
2 (50.8)	4000
3 (76.2)	5000

5.1.2 The size of the portion passing the No. 10 sieve shall be approximately 115 g for sandy soils and approximately 65 g for silt and clay soils.

5.2 Provision is made in Section 5 of Practice D 421 for weighing of the air-dry soil selected for purpose of tests, the separation of the soil on the No. 10 sieve by dry-sieving and washing, and the weighing of the washed and dried fraction retained on the No. 10 sieve. From these two masses the percentages retained and passing the No. 10 sieve can be calculated in accordance with 12.1.

NOTE 8—A check on the mass values and the thoroughness of pulverization of the clods may be secured by weighing the portion passing the No. 10 sieve and adding this value to the mass of the washed and oven-dried portion retained on the No. 10 sieve.

SIEVE ANALYSIS OF PORTION RETAINED ON NO. 10 (2.00-mm) SIEVE

6. Procedure

6.1 Separate the portion retained on the No. 10 (2.00-mm) sieve into a series of fractions using the 3-in. (75-mm), 2-in.

(50-mm), 1½-in. (37.5-mm), 1-in. (25.0-mm), ¾-in. (19.0-mm), ⅜-in. (9.5-mm), No. 4 (4.75-mm), and No. 10 sieves, or as many as may be needed depending on the sample, or upon the specifications for the material under test.

6.2 Conduct the sieving operation by means of a lateral and vertical motion of the sieve, accompanied by a jarring action in order to keep the sample moving continuously over the surface of the sieve. In no case turn or manipulate fragments in the sample through the sieve by hand. Continue sieving until not more than 1 mass % of the residue on a sieve passes that sieve during 1 min of sieving. When mechanical sieving is used, test the thoroughness of sieving by using the hand method of sieving as described above.

6.3 Determine the mass of each fraction on a balance conforming to the requirements of 3.1. At the end of weighing, the sum of the masses retained on all the sieves used should equal closely the original mass of the quantity sieved.

HYDROMETER AND SIEVE ANALYSIS OF PORTION PASSING THE NO. 10 (2.00-mm) SIEVE

7. Determination of Composite Correction for Hydrometer Reading

7.1 Equations for percentages of soil remaining in suspension, as given in 14.3, are based on the use of distilled or demineralized water. A dispersing agent is used in the water, however, and the specific gravity of the resulting liquid is appreciably greater than that of distilled or demineralized water.

7.1.1 Both soil hydrometers are calibrated at 68°F (20°C), and variations in temperature from this standard temperature produce inaccuracies in the actual hydrometer readings. The amount of the inaccuracy increases as the variation from the standard temperature increases.

7.1.2 Hydrometers are graduated by the manufacturer to be read at the bottom of the meniscus formed by the liquid on the stem. Since it is not possible to secure readings of soil suspensions at the bottom of the meniscus, readings must be taken at the top and a correction applied.

7.1.3 The net amount of the corrections for the three items enumerated is designated as the composite correction, and may be determined experimentally.

7.2 For convenience, a graph or table of composite corrections for a series of 1° temperature differences for the range of expected test temperatures may be prepared and used as needed. Measurement of the composite corrections may be made at two temperatures spanning the range of expected test temperatures, and corrections for the intermediate temperatures calculated assuming a straight-line relationship between the two observed values.

7.3 Prepare 1000 mL of liquid composed of distilled or demineralized water and dispersing agent in the same proportion as will prevail in the sedimentation (hydrometer) test. Place the liquid in a sedimentation cylinder and the cylinder in the constant-temperature water bath, set for one of the two temperatures to be used. When the temperature of the liquid becomes constant, insert the hydrometer, and, after a short interval to permit the hydrometer to come to the temperature of the liquid, read the hydrometer at the top of the meniscus

formed on the stem. For hydrometer 151H the composite correction is the difference between this reading and one; for hydrometer 152H it is the difference between the reading and zero. Bring the liquid and the hydrometer to the other temperature to be used, and secure the composite correction as before.

8. Hygroscopic Moisture

8.1 When the sample is weighed for the hydrometer test, weigh out an auxiliary portion of from 10 to 15 g in a small metal or glass container, dry the sample to a constant mass in an oven at 230 ± 9°F (110 ± 5°C), and weigh again. Record the masses.

9. Dispersion of Soil Sample

9.1 When the soil is mostly of the clay and silt sizes, weigh out a sample of air-dry soil of approximately 50 g. When the soil is mostly sand the sample should be approximately 100 g.

9.2 Place the sample in the 250-mL beaker and cover with 125 mL of sodium hexametaphosphate solution (40 g/L). Stir until the soil is thoroughly wetted. Allow to soak for at least 16 h.

9.3 At the end of the soaking period, disperse the sample further, using either stirring apparatus A or B. If stirring apparatus A is used, transfer the soil-water slurry from the beaker into the special dispersion cup shown in Fig. 2, washing any residue from the beaker into the cup with distilled or demineralized water (Note 9). Add distilled or demineralized water, if necessary, so that the cup is more than half full. Stir for a period of 1 min.

NOTE 9—A large size syringe is a convenient device for handling the water in the washing operation. Other devices include the wash-water bottle and a hose with nozzle connected to a pressurized distilled water tank.

9.4 If stirring apparatus B (Fig. 3) is used, remove the cover cap and connect the cup to a compressed air supply by means of a rubber hose. A air gage must be on the line between the cup and the control valve. Open the control valve so that the gage indicates 1 psi (7 kPa) pressure (Note 10). Transfer the soil-water slurry from the beaker to the air-jet dispersion cup by washing with distilled or demineralized water. Add distilled or demineralized water, if necessary, so that the total volume in the cup is 250 mL, but no more.

NOTE 10—The initial air pressure of 1 psi is required to prevent the soil-water mixture from entering the air-jet chamber when the mixture is transferred to the dispersion cup.

9.5 Place the cover cap on the cup and open the air control valve until the gage pressure is 20 psi (140 kPa). Disperse the soil according to the following schedule:

Plasticity Index	Dispersion Period, min
Under 5	5
6 to 20	10
Over 20	15

Soils containing large percentages of mica need be dispersed for only 1 min. After the dispersion period, reduce the gage pressure to 1 psi preparatory to transfer of soil-water slurry to the sedimentation cylinder.

10. Hydrometer Test

10.1 Immediately after dispersion, transfer the soil-water slurry to the glass sedimentation cylinder, and add distilled or demineralized water until the total volume is 1000 mL.

10.2 Using the palm of the hand over the open end of the cylinder (or a rubber stopper in the open end), turn the cylinder upside down and back for a period of 1 min to complete the agitation of the slurry (Note 11). At the end of 1 min set the cylinder in a convenient location and take hydrometer readings at the following intervals of time (measured from the beginning of sedimentation), or as many as may be needed, depending on the sample or the specification for the material under test: 2, 5, 15, 30, 60, 250, and 1440 min. If the controlled water bath is used, the sedimentation cylinder should be placed in the bath between the 2- and 5-min readings.

NOTE 11—The number of turns during this minute should be approximately 60, counting the turn upside down and back as two turns. Any soil remaining in the bottom of the cylinder during the first few turns should be loosened by vigorous shaking of the cylinder while it is in the inverted position.

10.3 When it is desired to take a hydrometer reading, carefully insert the hydrometer about 20 to 25 s before the reading is due to approximately the depth it will have when the reading is taken. As soon as the reading is taken, carefully remove the hydrometer and place it with a spinning motion in a graduate of clean distilled or demineralized water.

NOTE 12—It is important to remove the hydrometer immediately after each reading. Readings shall be taken at the top of the meniscus formed by the suspension around the stem, since it is not possible to secure readings at the bottom of the meniscus.

10.4 After each reading, take the temperature of the suspension by inserting the thermometer into the suspension.

11. Sieve Analysis

11.1 After taking the final hydrometer reading, transfer the suspension to a No. 200 (75- μ m) sieve and wash with tap water until the wash water is clear. Transfer the material on the No. 200 sieve to a suitable container, dry in an oven at $230 \pm 9^\circ\text{F}$ ($110 \pm 5^\circ\text{C}$) and make a sieve analysis of the portion retained, using as many sieves as desired, or required for the material, or upon the specification of the material under test.

CALCULATIONS AND REPORT

12. Sieve Analysis Values for the Portion Coarser than the No. 10 (2.00-mm) Sieve

12.1 Calculate the percentage passing the No. 10 sieve by dividing the mass passing the No. 10 sieve by the mass of soil originally split on the No. 10 sieve, and multiplying the result by 100. To obtain the mass passing the No. 10 sieve, subtract the mass retained on the No. 10 sieve from the original mass.

12.2 To secure the total mass of soil passing the No. 4 (4.75-mm) sieve, add to the mass of the material passing the No. 10 sieve the mass of the fraction passing the No. 4 sieve and retained on the No. 10 sieve. To secure the total mass of soil passing the $\frac{3}{8}$ -in. (9.5-mm) sieve, add to the total mass of soil passing the No. 4 sieve, the mass of the fraction passing the $\frac{3}{8}$ -in. sieve and retained on the No. 4 sieve. For the remaining sieves, continue the calculations in the same manner.

12.3 To determine the total percentage passing for each sieve, divide the total mass passing (see 12.2) by the total mass of sample and multiply the result by 100.

13. Hygroscopic Moisture Correction Factor

13.1 The hygroscopic moisture correction factor is the ratio between the mass of the oven-dried sample and the air-dry mass before drying. It is a number less than one, except when there is no hygroscopic moisture.

14. Percentages of Soil in Suspension

14.1 Calculate the oven-dry mass of soil used in the hydrometer analysis by multiplying the air-dry mass by the hygroscopic moisture correction factor.

14.2 Calculate the mass of a total sample represented by the mass of soil used in the hydrometer test, by dividing the oven-dry mass used by the percentage passing the No. 10 (2.00-mm) sieve, and multiplying the result by 100. This value is the weight W in the equation for percentage remaining in suspension.

14.3 The percentage of soil remaining in suspension at the level at which the hydrometer is measuring the density of the suspension may be calculated as follows (Note 13): For hydrometer 151H:

$$P = [(100\ 000/W) [m]P5\ G/(G - G_1)](R - G_1) \quad (1)$$

NOTE 13—The bracketed portion of the equation for hydrometer 151H is constant for a series of readings and may be calculated first and then multiplied by the portion in the parentheses.

For hydrometer 152H:

$$P = (Ra/W) [m]P5\ 100 \quad (2)$$

where:

a = correction factor to be applied to the reading of hydrometer 152H. (Values shown on the scale are computed using a specific gravity of 2.65. Correction factors are given in Table 1),

P = percentage of soil remaining in suspension at the level at which the hydrometer measures the density of the suspension,

R = hydrometer reading with composite correction applied (Section 7),

W = oven-dry mass of soil in a total test sample represented by mass of soil dispersed (see 14.2), g,

G = specific gravity of the soil particles, and

G_1 = specific gravity of the liquid in which soil particles are suspended. Use numerical value of one in both instances in the equation. In the first instance any possible variation produces no significant effect, and in the second instance, the composite correction for R is based on a value of one for G_1 .

15. Diameter of Soil Particles

15.1 The diameter of a particle corresponding to the percentage indicated by a given hydrometer reading shall be calculated according to Stokes' law (Note 14), on the basis that a particle of this diameter was at the surface of the suspension at the beginning of sedimentation and had settled to the level at

TABLE 1 Values of Correction Factor, α , for Different Specific Gravities of Soil Particles^A

Specific Gravity	Correction Factor ^A
2.95	0.94
2.90	0.95
2.85	0.96
2.80	0.97
2.75	0.98
2.70	0.99
2.65	1.00
2.60	1.01
2.55	1.02
2.50	1.03
2.45	1.05

^AFor use in equation for percentage of soil remaining in suspension when using Hydrometer 152H.

which the hydrometer is measuring the density of the suspension. According to Stokes' law: see Table 2

$$D = \sqrt{[30n/980(G - G_1)] [m]P5 L/T} \quad (3)$$

where:

- D = diameter of particle, mm,
- n = coefficient of viscosity of the suspending medium (in this case water) in poises (varies with changes in temperature of the suspending medium),
- L = distance from the surface of the suspension to the level at which the density of the suspension is being measured, cm. (For a given hydrometer and sedimentation cylinder, values vary according to the hydrometer readings. This distance is known as effective depth (see Table 2)),
- T = interval of time from beginning of sedimentation to the taking of the reading, min,
- G = specific gravity of soil particles, and
- G_1 = specific gravity (relative density) of suspending medium (value may be used as 1.000 for all practical purposes).

NOTE 14—Since Stokes' law considers the terminal velocity of a single sphere falling in an infinity of liquid, the sizes calculated represent the diameter of spheres that would fall at the same rate as the soil particles.

15.2 For convenience in calculations the above equation may be written as follows: see Table 3

$$D = K\sqrt{LT} \quad (4)$$

where:

- K = constant depending on the temperature of the suspension and the specific gravity of the soil particles. Values of K for a range of temperatures and specific gravities are given in Table 3. The value of K does not change for a series of readings constituting a test, while values of L and T do vary.

15.3 Values of D may be computed with sufficient accuracy, using an ordinary 10-in. slide rule.

NOTE 15—The value of L is divided by T using the A - and B -scales, the square root being indicated on the D -scale. Without ascertaining the value of the square root it may be multiplied by K , using either the C - or CI -scale.

16. Sieve Analysis Values for Portion Finer than No. 10 (2.00-mm) Sieve

16.1 Calculation of percentages passing the various sieves

TABLE 2 Values of Effective Depth Based on Hydrometer and Sedimentation Cylinder of Specified Sizes^A

1.036	6.8				
1.037	6.5				
1.038	6.2				

^AValues of effective depth are calculated from the equation:

$$L = L_1 + 1/2 [L_2 - (V_B/A)] \quad (5)$$

where:

- L = effective depth, cm,
- L_1 = distance along the stem of the hydrometer from the top of the bulb to the mark for a hydrometer reading, cm,
- L_2 = overall length of the hydrometer bulb, cm,
- V_B = volume of hydrometer bulb, cm³, and
- A = cross-sectional area of sedimentation cylinder, cm²

Values used in calculating the values in Table 2 are as follows:

For both hydrometers, 151H and 152H:

- L_2 = 14.0 cm
- V_B = 67.0 cm³
- A = 27.8 cm²

For hydrometer 151H:

- L_1 = 10.5 cm for a reading of 1.000
- = 2.3 cm for a reading of 1.031

For hydrometer 152H:

- L_1 = 10.5 cm for a reading of 0 g/litre
- = 2.3 cm for a reading of 50 g/litre

used in sieving the portion of the sample from the hydrometer test involves several steps. The first step is to calculate the mass of the fraction that would have been retained on the No. 10

TABLE 3 Values of K for Use in Equation for Computing Diameter of Particle in Hydrometer Analysis

sieve had it not been removed. This mass is equal to the total percentage retained on the No. 10 sieve (100 minus total percentage passing) times the mass of the total sample represented by the mass of soil used (as calculated in 14.2), and the result divided by 100.

16.2 Calculate next the total mass passing the No. 200 sieve. Add together the fractional masses retained on all the sieves, including the No. 10 sieve, and subtract this sum from the mass of the total sample (as calculated in 14.2).

16.3 Calculate next the total masses passing each of the other sieves, in a manner similar to that given in 12.2.

16.4 Calculate last the total percentages passing by dividing the total mass passing (as calculated in 16.3) by the total mass of sample (as calculated in 14.2), and multiply the result by 100.

17. Graph

17.1 When the hydrometer analysis is performed, a graph of the test results shall be made, plotting the diameters of the particles on a logarithmic scale as the abscissa and the percentages smaller than the corresponding diameters to an arithmetic scale as the ordinate. When the hydrometer analysis is not made on a portion of the soil, the preparation of the graph is optional, since values may be secured directly from tabulated data.

18. Report

- 18.1 The report shall include the following:
 - 18.1.1 Maximum size of particles,
 - 18.1.2 Percentage passing (or retained on) each sieve, which may be tabulated or presented by plotting on a graph (Note 16),
 - 18.1.3 Description of sand and gravel particles:
 - 18.1.3.1 Shape—rounded or angular,
 - 18.1.3.2 Hardness—hard and durable, soft, or weathered and friable,
 - 18.1.4 Specific gravity, if unusually high or low,
 - 18.1.5 Any difficulty in dispersing the fraction passing the No. 10 (2.00-mm) sieve, indicating any change in type and amount of dispersing agent, and
 - 18.1.6 The dispersion device used and the length of the dispersion period.

NOTE 16—This tabulation of graph represents the gradation of the sample tested. If particles larger than those contained in the sample were removed before testing, the report shall so state giving the amount and maximum size.

18.2 For materials tested for compliance with definite specifications, the fractions called for in such specifications shall be reported. The fractions smaller than the No. 10 sieve shall be read from the graph.

18.3 For materials for which compliance with definite specifications is not indicated and when the soil is composed almost entirely of particles passing the No. 4 (4.75-mm) sieve, the results read from the graph may be reported as follows:

- (1) Gravel, passing 3-in. and retained on No. 4 sieve %
- (2) Sand, passing No. 4 sieve and retained on No. 200 sieve %
 - (a) Coarse sand, passing No. 4 sieve and retained on No. 10 sieve %
 - (b) Medium sand, passing No. 10 sieve and retained on No. 40 sieve %
 - (c) Fine sand, passing No. 40 sieve and retained on No. 200 sieve %
- (3) Silt size, 0.074 to 0.005 mm %
- (4) Clay size, smaller than 0.005 mm %
 - Colloids, smaller than 0.001 mm %

18.4 For materials for which compliance with definite specifications is not indicated and when the soil contains material retained on the No. 4 sieve sufficient to require a sieve analysis on that portion, the results may be reported as follows (Note 17):

Scope:

This method covers the procedure for the electrometric measurement of oxidation-reduction potential in potable waters and wastewaters. This method is also modified to perform Oxidation-Reduction Potential on solid waste and soil samples. The electrodes are reliable in nearly all aqueous solutions and are not subject to interference from color, turbidity, colloidal matter, or suspended matter. Applicable concentration ranges and reporting limits are found in the LIMS.

Basic Principles:

Oxidation-reduction potential is defined as the electromotive force between a noble metal electrode and a reference electrode when immersed in a solution, referred to the standard hydrogen electrode. The oxidation-reduction potential electrodes are inert and measure the ratio of the activities of the oxidized to the reduced species in the process reactions.

Interferences:

Particulate matter present in a sample has the possibility of causing interference to the electrode.

Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See the *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability.

Analysts are considered proficient when they have successfully completed a Demonstration of Capability. This consists of four laboratory control samples that are carried through all steps of the analysis and that meet the defined acceptance criteria. Demonstration of Capability is performed annually and documentation is maintained in each individual's training records.

Sample Collection, Preservation, and Handling:

Samples for this analysis must be in an unpreserved container. Water samples are collected in unpreserved plastic or glass containers. Solid samples are collected in unpreserved glass containers. The samples are stored at $4^{\circ} \pm 2^{\circ}\text{C}$. The samples are analyzed as soon as possible after collection. There is no defined holding time for this analysis.

Apparatus and Equipment:

1. pH meter – A pH meter capable of storing and calibrating on a Redox standard solution must be used.
2. Oxidation-reduction combination electrode – Platinum, with appropriate filling solution.

Reagents and Standards:

Alternative weights and volumes are used as long as final concentrations remain unchanged. Refer to LOM-SOP-ES-225 for appropriate labeling and documentation.

1. ORP Standard - Purchased; The expiration date must be the manufacturer's suggested expiration date. See container for storage information.
2. 0.5 N CaCl_2 – Using a 2-L volumetric flask, dissolve $111 \pm .5$ g CaCl_2 and dilute to 2 L with reagent water. Solution expires 6 months from the date of preparation. Store at room temperature.
3. Ag/AgCl – Reference Electrode filling solution. Store at room temperature. Re-evaluate yearly.

Calibration:

Not applicable to this procedure

Procedure:

NOTE: Electrode Preparation - Remove traces of foreign matter and oily residues, and change filling solution if necessary.

1. Assemble pH meter and connect oxidation-reduction potential electrode. Set the meter to RmV.
2. Place the oxidation-reduction potential electrode into approximately 50 mL of ORP Standard. Make sure the reading falls within the acceptance range before proceeding.
3. Repeat this procedure until two successive readings of sample differ by no more than 10 mV.
4. For the result, take the average of the two successive trials. Record this reading as the LCS/CCV.
5. When analyzing soils, make a 1:1 slurry by adding equal amount of sample and reagent water to a beaker.

NOTE: It is possible to make a 1:1 slurry by using equal amounts of 0.5 N CaCl₂ and sample to a beaker at the client's request.
6. Use a stirring rod and mix the sample gently.
7. Add magnetic stir bar and stir for five minutes.
8. When the reading is stabilized read the millivolt potential of the solution.
9. Repeat this procedure until two successive readings of sample differ by no more than 10 mV. For the result, take the average of the two successive trials.
10. When analyzing waters, use 50 mL sample.

Calculations:

The oxidation-reduction potential is related to the reference electrode used in the measurement. Calculate the oxidation-reduction potential of the sample, in millivolts, referred to the hydrogen scale:

$$E_{(h)} = E_{(obs)} + E_{(ref)}$$

Where:

$E_{(h)}$ = oxidation-reduction potential referred to the hydrogen scale, mV

$E_{(obs)}$ = observed oxidation-reduction potential of the platinum electrode, mV

$E_{(ref)}$ = oxidation-reduction potential of the reference electrode as related to the hydrogen standards, mV (see Table I)

Statistical Information/Method Performance:

See LIMS for MDL/ QC windows.

Quality Assurance/Quality Control:

ORP standard is analyzed at the beginning of each batch as a laboratory control standard (LCS) and is repeated after every 10 samples as a CCV. The ORP standard is also analyzed at the end of each batch. The acceptance range for this solution is the certified value ± 30 mV or the manufactures suggested range, whichever is less.

Two duplicates must be analyzed for each batch of 20 samples.

See LIMS for current quality control acceptance windows. Refer to SOP-WQ-017 if any of the QC samples do not meet required specifications.

USEPA Method 6010C / 1-P-QM-WI-9015160

METHOD 6010C

INDUCTIVELY COUPLED PLASMA-ATOMIC EMISSION SPECTROMETRY

SW-846 is not intended to be an analytical training manual. Therefore, method procedures are written based on the assumption that they will be performed by analysts who are formally trained in at least the basic principles of chemical analysis and in the use of the subject technology.

In addition, SW-846 methods, with the exception of required method use for the analysis of method-defined parameters, are intended to be guidance methods which contain general information on how to perform an analytical procedure or technique which a laboratory can use as a basic starting point for generating its own detailed Standard Operating Procedure (SOP), either for its own general use or for a specific project application. The performance data included in this method are for guidance purposes only, and are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

1.0 SCOPE AND APPLICATION

1.1 Inductively coupled plasma-atomic emission spectrometry (ICP-AES) may be used to determine trace elements in solution. With the exception of groundwater samples, all aqueous and solid matrices need acid digestion prior to analysis. Groundwater samples that were prefiltered and acidified will not need acid digestion. Samples which are not digested need either an internal standard or should be matrix-matched with the standards. If either option is used, instrument software should be programmed to correct for intensity differences of the internal standard between samples and standards. Refer to Chapter Three, "Inorganic Analytes," for a listing of digestion procedures that may be appropriate. The following analytes have been determined by this method:

Element	Symbol	CAS Number	Element	Symbol	CAS Number
Aluminum	Al	7429-90-5	Mercury	Hg	7439-97-6
Antimony	Sb	7440-36-0	Molybdenum	Mo	7439-98-7
Arsenic	As	7440-38-2	Nickel	Ni	7440-02-0
Barium	Ba	7440-39-3	Phosphorus	P	7723-14-0
Beryllium	Be	7440-41-7	Potassium	K	7440-09-7
Boron	B	7440-42-8	Selenium	Se	7782-49-2
Cadmium	Cd	7440-43-9	Silica	SiO ₂	7631-86-9
Calcium	Ca	7440-70-2	Silver	Ag	7440-22-4
Chromium	Cr	7440-47-3	Sodium	Na	7440-23-5
Cobalt	Co	7440-48-4	Strontium	Sr	7440-24-6
Copper	Cu	7440-50-8	Thallium	Tl	7440-28-0
Iron	Fe	7439-89-6	Tin	Sn	7440-31-5
Lead	Pb	7439-92-1	Titanium	Ti	7440-32-6
Lithium	Li	7439-93-2	Vanadium	V	7440-62-2

Element	Symbol	CAS Number	Element	Symbol	CAS Number
Magnesium	Mg	7439-95-4	Zinc	Zn	7440-66-6
Manganese	Mn	7439-96-5			

CAS Number: Chemical Abstract Service Registry Number.

1.2 Table 1 lists all of the elements for which this method was validated. The sensitivity and the optimum and linear ranges for each element will vary with the wavelength, spectrometer, matrix, and operating conditions. Table 1 lists the recommended analytical wavelengths and estimated instrumental detection limits (IDLs) for the elements in clean aqueous matrices with insignificant background interferences. Other elements and matrices may be analyzed by this method if appropriate performance at the concentrations of interest (see Sec. 9.0) is demonstrated.

1.3 Analysts should clearly understand the data quality objectives prior to analysis and must document and have on file the required initial demonstration performance data described in the following sections prior to using the method for analysis.

1.4 Prior to employing this method, analysts are advised to consult the each preparative method that may be employed in the overall analysis (e.g., a 3000 series method) for additional information on quality control procedures, development of QC acceptance criteria, calculations, and general guidance. Analysts also should consult the disclaimer statement at the front of the manual and the information in Chapter Two for guidance on the intended flexibility in the choice of methods, apparatus, materials, reagents, and supplies, and on the responsibilities of the analyst for demonstrating that the techniques employed are appropriate for the analytes of interest, in the matrix of interest, and at the levels of concern.

In addition, analysts and data users are advised that, except where explicitly specified in a regulation, the use of SW-846 methods is *not* mandatory in response to Federal testing requirements. The information contained in this method is provided by EPA as guidance to be used by the analyst and the regulated community in making judgments necessary to generate results that meet the data quality objectives for the intended application.

1.5 Use of this method is restricted to use by, or under supervision of, spectroscopists appropriately experienced and trained in the correction of spectral, chemical, and physical interferences described in this method. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 Prior to analysis, samples must be solubilized or digested using the appropriate sample preparation methods (see Chapter Three). When analyzing groundwater samples for dissolved constituents, acid digestion is not necessary if the samples are filtered and acid preserved prior to analysis (refer to Sec. 1.1).

2.2 This method describes multielemental determinations by ICP-AES using sequential or simultaneous optical systems and axial or radial viewing of the plasma. The instrument measures characteristic emission spectra by optical spectrometry. Samples are nebulized and the resulting aerosol is transported to the plasma torch. Element-specific emission spectra are produced by a radio-frequency inductively coupled plasma. The spectra are dispersed by a grating spectrometer, and the intensities of the emission lines are monitored by photosensitive devices.

2.3 Background correction is required for trace element determination. Background emission must be measured adjacent to analyte lines on samples during analysis. The position selected for the background-intensity measurement, on either or both sides of the analytical line, will be determined by the complexity of the spectrum adjacent to the analyte line. The position used should be as free as possible from spectral interference and should reflect the same change in background intensity as occurs at the analyte wavelength measured. Background correction is not required in cases of line broadening where a background correction measurement would actually degrade the analytical result. The possibility of additional interferences identified in Sec. 4.0 should also be recognized and appropriate corrections made; tests for their presence are described in Secs. 9.6 and 9.7. Alternatively, users may choose multivariate calibration methods. In this case, point selections for background correction are superfluous since whole spectral regions are processed.

3.0 DEFINITIONS

Refer to Chapter One, Chapter Three, and the manufacturer's instructions for definitions that may be relevant to this procedure.

4.0 INTERFERENCES

4.1 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks. Specific selection of reagents and purification of solvents by distillation in all-glass systems may be necessary. Refer to each method to be used for specific guidance on quality control procedures and to Chapter Three for general guidance on the cleaning of glassware. Also refer to the preparative methods to be used for discussions on interferences.

4.2 Spectral interferences are caused by background emission from continuous or recombination phenomena, stray light from the line emission of high concentration elements, overlap of a spectral line from another element, or unresolved overlap of molecular band spectra.

4.2.1 Compensation for background emission and stray light can usually be conducted by subtracting the background emission determined by measurements adjacent to the analyte wavelength peak. Spectral scans of samples or single element solutions in the analyte regions may indicate when alternate wavelengths are desirable because of severe spectral interference. These scans will also show whether the most appropriate estimate of the background emission is provided by an interpolation from measurements on both sides of the wavelength peak or by measured emission on only one side. The locations selected for the measurement of background intensity will be determined by the complexity of the spectrum adjacent to the wavelength peak. The locations used for routine measurement must be free of off-line spectral interference (interelement or molecular) or adequately corrected to reflect the same change in background intensity as occurs at the wavelength peak. For multivariate methods using whole spectral regions, background scans should be included in the correction algorithm. Off-line spectral interferences are handled by including spectra on interfering species in the algorithm.

4.2.2 To determine the appropriate location for off-line background correction, the user must scan the area on either side adjacent to the wavelength and record the apparent emission intensity from all other method analytes. This spectral information must

be documented and kept on file. The location selected for background correction must be either free of off-line interelement spectral interference or a computer routine must be used for automatic correction on all determinations. If a wavelength other than the recommended wavelength is used, the analyst must determine and document both the overlapping and nearby spectral interference effects from all method analytes and common elements and provide for their automatic correction on all analyses. Tests to determine spectral interference must be done using analyte concentrations that will adequately describe the interference. Normally, 100 mg/L single-element solutions are sufficient. However, for analytes such as iron that may be found in the sample at high concentration, a more appropriate test would be to use a concentration near the upper limit of the analytical range (refer to Chapter Three).

4.2.3 Spectral overlaps may be avoided by using an alternate wavelength or can be compensated for by equations that correct for interelement contributions. Instruments that use equations for interelement correction require that the interfering elements be analyzed at the same time as the element of interest. When operative and uncorrected, interferences will produce false positive or positively biased determinations. More extensive information on interferant effects at various wavelengths and resolutions is available in reference wavelength tables and books. Users may apply interelement correction equations determined on their instruments with tested concentration ranges to compensate (off-line or on-line) for the effects of interfering elements. Some potential spectral interferences observed for the recommended wavelengths are given in Table 2. For multivariate calibration methods using whole spectral regions, spectral interferences are handled by including spectra of the interfering elements in the algorithm. The interferences listed are only those that occur between method analytes. Only interferences of a direct overlap nature are listed. These overlaps were observed with a single instrument having a working resolution of 0.035 nm.

4.2.4 When using interelement correction equations, the interference may be expressed as analyte concentration equivalents (i.e., false positive analyte concentrations) arising from 100 mg/L of the interference element. For example, if As is to be determined at 193.696 nm in a sample containing approximately 10 mg/L of Al, according to Table 2, 100 mg/L of Al will yield a false positive signal for an As level equivalent to approximately 1.3 mg/L. Therefore, the presence of 10 mg/L of Al will result in a false positive signal for As equivalent to approximately 0.13 mg/L. The user is cautioned that other instruments may exhibit somewhat different levels of interference than those shown in Table 2. These data are provided for guidance purposes only. The interference effects must be evaluated for each individual instrument, since the intensities will vary.

4.2.5 Interelement corrections will vary for the same emission line among instruments because of differences in resolution, as determined by the grating, the entrance and exit slit widths, and by the order of dispersion. Interelement corrections will also vary depending upon the choice of background correction points. Selecting a background correction point where an interfering emission line may appear should be avoided when practical. Interelement corrections that constitute a major portion of an emission signal may not yield accurate data. Users should continuously note that some samples may contain uncommon elements that could contribute spectral interferences.

4.2.6 The interference effects must be evaluated for each individual instrument, whether configured as a sequential or simultaneous instrument. For each instrument, intensities will vary not only with optical resolution but also with operating conditions (such as power, viewing height and argon flow rate). When using the recommended wavelengths, the analyst is required to determine and document for each wavelength the effect from referenced interferences (Table 2) as well as any other suspected

interferences that may be specific to the instrument or matrix. The analyst is encouraged to utilize a computer routine for automatic correction on all analyses.

4.2.7 Users of sequential instruments must verify the absence of spectral interference by scanning over a range of 0.5 nm centered on the wavelength of interest for several samples. The range for lead, for example, would be from 220.6 to 220.1 nm. This procedure must be repeated whenever a new matrix is to be analyzed and when a new calibration curve using different instrumental conditions is to be prepared. Samples that show an elevated background emission across the range may be background corrected by applying a correction factor equal to the emission adjacent to the line or at two points on either side of the line and interpolating between them. An alternate wavelength that does not exhibit a background shift or spectral overlap may also be used.

4.2.8 If the correction routine is operating properly, the determined apparent analyte(s) concentration from analysis of each interference solution should fall within a specific concentration range around the calibration blank. The concentration range is calculated by multiplying the concentration of the interfering element by the value of the correction factor being tested and dividing by 10. If after the subtraction of the calibration blank the apparent analyte concentration falls outside of this range, in either a positive or negative direction, a change in the correction factor of more than 10% should be suspected. The cause of the change should be determined and corrected and the correction factor updated. The interference check solutions should be analyzed more than once to confirm a change has occurred. Adequate rinse time between solutions and before analysis of the calibration blank will assist in the confirmation.

4.2.9 When interelement corrections are applied, their accuracy should be verified daily, by analyzing spectral interference check solutions. The correction factors or multivariate correction matrices tested on a daily basis must be within the 20% criteria for five consecutive days. All interelement spectral correction factors or multivariate correction matrices must be verified and updated every six months or when an instrumentation change occurs, such as one in the torch, nebulizer, injector, or plasma conditions. Standard solutions should be inspected to ensure that there is no contamination that may be perceived as a spectral interference.

4.2.10 When interelement corrections are not used, verification of absence of interferences is required.

4.2.10.1 One method to verify the absence of interferences is to use a computer software routine for comparing the determinative data to established limits for notifying the analyst when an interfering element is detected in the sample at a concentration that will produce either an apparent false positive concentration (i.e., greater than the analyte instrument detection limit), or a false negative analyte concentration (i.e., less than the lower control limit of the calibration blank defined for a 99% confidence interval).

4.2.10.2 Another way to verify the absence of interferences is to analyze an interference check solution which contains similar concentrations of the major components of the samples (>10 mg/L) on a continuing basis to verify the absence of effects at the wavelengths selected. These data must be kept on file with the sample analysis data. If the check solution confirms an operative interference that is $\leq 20\%$ of the analyte concentration, the analyte must be determined using (1) analytical and background correction wavelengths (or spectral regions) free of the interference, (2) by an alternative wavelength, or (3) by another documented test procedure.

4.3 Physical interferences are effects associated with the sample nebulization and transport processes. Changes in viscosity and surface tension can cause significant inaccuracies, especially in samples containing high dissolved solids or high acid concentrations. If physical interferences are present, they must be reduced by diluting the sample, by using a peristaltic pump, by using an internal standard, or by using a high solids nebulizer. Another problem that can occur with high dissolved solids is salt buildup at the tip of the nebulizer, affecting aerosol flow rate and causing instrumental drift. The problem can be controlled by wetting the argon prior to nebulization, by using a tip washer, by using a high solids nebulizer, or by diluting the sample. Also, it has been reported that better control of the argon flow rate, especially to the nebulizer, improves instrument performance. This may be accomplished with the use of mass flow controllers. The test described in Sec. 9.9 will help determine if a physical interference is present.

4.4 Chemical interferences include molecular compound formation, ionization effects, and solute vaporization effects. Normally, these effects are not significant with the ICP technique, but if observed, can be minimized by careful selection of operating conditions (incident power, observation position, and so forth), by buffering of the sample, by matrix matching, and by standard addition procedures. Chemical interferences are highly dependent on matrix type and the specific analyte element. The analyst is encouraged to review the information in all of Sec. 4.0 to deal with the majority of interferences likely to be encountered when using this method.

4.4.1 The method of standard additions (MSA) can be useful when certain interferences are encountered. Refer to Method 7000 for a more detailed discussion of the MSA.

4.4.2 An alternative to using the method of standard additions is to use the internal standard technique, which involves adding one or more elements that are both not found in the samples and verified to not cause an interelement spectral interference to the samples, standards, and blanks. Yttrium or scandium are often used. The concentration should be sufficient for optimum precision, but not so high as to alter the salt concentration of the matrix. The element intensity is used by the instrument as an internal standard to ratio the analyte intensity signals for both calibration and quantitation. This technique is very useful in overcoming matrix interferences, especially in high solids matrices.

4.5 Memory interferences result when analytes in a previous sample contribute to the signals measured in a new sample. Memory effects can result from sample deposition on the uptake tubing to the nebulizer and from the build up of sample material in the plasma torch and spray chamber. The site where these effects occur is dependent on the element and can be minimized by flushing the system with a rinse blank between samples. The possibility of memory interferences should be recognized within an analytical run and suitable rinse times should be used to reduce them. The rinse times necessary for a particular element must be estimated prior to analysis. This may be achieved by aspirating a standard containing elements at a concentration ten times the usual amount or at the top of the linear dynamic range. The aspiration time for this sample should be the same as a normal sample analysis period, followed by analysis of the rinse blank at designated intervals. Note the length of time necessary for reducing analyte signals to "equal to" or "less than" the lower limit of quantitation. Until the required rinse time is established, the rinse period should be at least 60 sec between samples and standards. If a memory interference is suspected, the sample must be reanalyzed after a rinse period of sufficient length. Alternate rinse times may be established by the analyst based upon the project-specific DQOs.

4.6 Users are advised that high salt concentrations can cause analyte signal suppressions and confuse interference tests. If the instrument does not display negative

values, fortify the interference check solution with the elements of interest at 0.5 to 1 mg/L and measure the added standard concentration accordingly. Concentrations should be within 20% of the true spiked concentration or dilution of the samples will be necessary. In the absence of a measurable analyte, overcorrection could go undetected if a negative value is reported as zero.

4.7 The dashes in Table 2 indicate that no measurable interferences were observed even at higher interferant concentrations. Generally, interferences were discernible if they produced peaks, or background shifts, corresponding to 2 to 5% of the peaks generated by the analyte concentrations.

4.8 The calibration blank (Sec. 7.5.1) may restrict the sensitivity of the quantitation limit or degrade the precision and accuracy of the analysis. Consult Chapter Three for recommended precautions and procedures necessary in reducing the magnitude and variability of the calibration blank.

5.0 SAFETY

5.1 This method does not address all safety issues associated with its use. The laboratory is responsible for maintaining a safe work environment and a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method. A reference file of material safety data sheets (MSDSs) should be available to all personnel involved in these analyses.

5.2 Concentrated nitric and hydrochloric acids are moderately toxic and extremely irritating to skin and mucus membranes. Use these reagents in a hood and if eye or skin contact occurs, flush with large volumes of water. Always wear safety glasses or a shield for eye protection when working with these reagents. Hydrofluoric acid is a very toxic acid and penetrates the skin and tissues deeply if not treated immediately. Injury occurs in two stages; first, by hydration that induces tissue necrosis and then by penetration of fluoride ions deep into the tissue and by reaction with calcium. Boric acid and other complexing reagents and appropriate treatment agents should be administered immediately. Consult appropriate safety literature and have the appropriate treatment materials readily available prior to working with this acid. See Method 3052 for specific suggestions for handling hydrofluoric acid from a safety and an instrument standpoint.

5.3 Many metal salts are extremely toxic if inhaled or swallowed. Extreme care must be taken to ensure that samples and standards are handled properly and that all exhaust gases are properly vented. Wash hands thoroughly after handling.

5.4 The acidification of samples containing reactive materials may result in the release of toxic gases, such as cyanides or sulfides. For this reason, the acidification and digestion of samples should be performed in an approved fume hood.

6.0 EQUIPMENT AND SUPPLIES

6.1 Inductively coupled argon plasma emission spectrometer

6.1.1 Computer-controlled emission spectrometer with background correction.

6.1.2 Radio-frequency generator compliant with FCC regulations.

- 6.1.3 Optional mass flow controller for argon nebulizer gas supply.
- 6.1.4 Optional peristaltic pump.
- 6.1.5 Optional autosampler.
- 6.1.6 Argon gas supply -- high purity.
- 6.2 Volumetric flasks of suitable precision and accuracy.
- 6.3 Volumetric pipets of suitable precision and accuracy.

7.0 REAGENTS AND STANDARDS

7.1 Reagent- or trace metals-grade chemicals must be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is in question, analyze for contamination. If the concentration of the contamination is less than the lower limit of quantitation, then the reagent is acceptable.

7.1.1 Hydrochloric acid (conc), HCl.

7.1.2 Hydrochloric acid HCl (1:1) -- Add 500 mL concentrated HCl to 400 mL water and dilute to 1 L in an appropriately- sized beaker.

7.1.3 Nitric acid (conc), HNO₃.

7.1.4 Nitric acid, HNO₃ (1:1) -- Add 500 mL concentrated HNO₃ to 400 mL water and dilute to 1 L in an appropriately-sized beaker.

7.2 Reagent water -- All references to water in the method refer to reagent water, unless otherwise specified. Reagent water must be free of interferences.

7.3 Standard stock solutions may be purchased or prepared from ultra-high purity grade chemicals or metals (99.99% pure or greater). With several exceptions specifically noted, all salts must be dried for 1 hr at 105 °C.

CAUTION: Many metal salts are extremely toxic if inhaled or swallowed. Wash hands thoroughly after handling.

Typical stock solution preparation procedures follow. Concentrations are calculated based upon the weight of pure metal added, or with the use of the element fraction and the weight of the metal salt added.

NOTE: This section does not apply when analyzing samples prepared by Method 3040.

NOTE: The weight of the analyte is expressed to four significant figures for consistency with the weights below because rounding to two decimal places can contribute up to 4% error for some of the compounds.

For metals:

$$\text{Concentration (ppm)} = \frac{\text{weight (mg)}}{\text{volume (L)}}$$

For metal salts:

$$\text{Concentration (ppm)} = \frac{\text{weight (mg)} \times \text{mole fraction}}{\text{volume (L)}}$$

7.3.1 Aluminum solution, stock, 1 mL = 1000 µg of Al

Dissolve 1.000 g of aluminum metal, accurately weighed to at least four significant figures, in an acid mixture of 4.0 mL of HCl (1:1) and 1.0 mL of concentrated HNO₃ in a beaker. Warm beaker slowly to dissolve the metal. When dissolution is complete, transfer solution quantitatively to a 1000-mL volumetric flask, add an additional 10.0 mL of HCl (1:1) and dilute to volume with reagent water.

7.3.2 Antimony solution, stock, 1 mL = 1000 µg of Sb

Dissolve 2.6673 g of K(SbO)C₄H₄O₆ (element fraction Sb = 0.3749), accurately weighed to at least four significant figures, in reagent water, add 10 mL of HCl (1:1), and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.3 Arsenic solution, stock, 1 mL = 1000 µg of As

Dissolve 1.3203 g of As₂O₃ (element fraction As = 0.7574), accurately weighed to at least four significant figures, in 100 mL of reagent water containing 0.4 g of NaOH. Acidify the solution with 2 mL of concentrated HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.4 Barium solution, stock, 1 mL = 1000 µg of Ba

Dissolve 1.5163 g of BaCl₂ (element fraction Ba = 0.6595), dried at 250 °C for 2 hr, accurately weighed to at least four significant figures, in 10 mL of reagent water with 1 mL of HCl (1:1). Add 10.0 mL of HCl (1:1) and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.5 Beryllium solution, stock, 1 mL = 1000 µg of Be

Do not dry. Dissolve 19.6463 g of BeSO₄·4H₂O (element fraction Be = 0.0509), accurately weighed to at least four significant figures, in reagent water, add 10.0 mL of concentrated HNO₃, and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.6 Boron solution, stock, 1 mL = 1000 µg of B

Do not dry. Dissolve 5.716 g of anhydrous H₃BO₃ (B fraction = 0.1749), accurately weighed to at least four significant figures, in reagent water and dilute in a 1-L

volumetric flask with reagent water. Transfer immediately after mixing in a clean polytetrafluoroethylene (PTFE) bottle to minimize any leaching of boron from the glass container. The use of a non-glass volumetric flask is recommended to avoid boron contamination from glassware.

7.3.7 Cadmium solution, stock, 1 mL = 1000 µg of Cd

Dissolve 1.1423 g of CdO (element fraction Cd = 0.8754), accurately weighed to at least four significant figures, in a minimum amount of (1:1) HNO₃. Heat to increase the rate of dissolution. Add 10.0 mL of concentrated HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.8 Calcium solution, stock, 1 mL = 1000 µg of Ca

Suspend 2.4969 g of CaCO₃ (element Ca fraction = 0.4005), dried at 180 °C for 1 hr before weighing, accurately weighed to at least four significant figures, in reagent water and dissolve cautiously with a minimum amount of (1:1) HNO₃. Add 10.0 mL of concentrated HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.9 Chromium solution, stock, 1 mL = 1000 µg of Cr

Dissolve 1.9231 g of CrO₃ (element fraction Cr = 0.5200), accurately weighed to at least four significant figures, in reagent water. When dissolution is complete, acidify with 10 mL of concentrated HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.10 Cobalt solution, stock, 1 mL = 1000 µg of Co

Dissolve 1.000 g of cobalt metal, accurately weighed to at least four significant figures, in a minimum amount of (1:1) HNO₃. Add 10.0 mL of HCl (1:1) and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.11 Copper solution, stock, 1 mL = 1000 µg of Cu

Dissolve 1.2564 g of CuO (element fraction Cu = 0.7989), accurately weighed to at least four significant figures, in a minimum amount of (1:1) HNO₃. Add 10.0 mL of concentrated HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.12 Iron solution, stock, 1 mL = 1000 µg of Fe

Dissolve 1.4298 g of Fe₂O₃ (element fraction Fe = 0.6994), accurately weighed to at least four significant figures, in a warm mixture of 20 mL HCl (1:1) and 2 mL of concentrated HNO₃. Cool, add an additional 5.0 mL of concentrated HNO₃, and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.13 Lead solution, stock, 1 mL = 1000 µg of Pb

Dissolve 1.5985 g of Pb(NO₃)₂ (element fraction Pb = 0.6256), accurately weighed to at least four significant figures, in a minimum amount of (1:1) HNO₃. Add 10 mL (1:1) HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.14 Lithium solution, stock, 1 mL = 1000 µg of Li

Dissolve 5.3248 g of lithium carbonate (element fraction Li = 0.1878), accurately weighed to at least four significant figures, in a minimum amount of HCl (1:1) and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.15 Magnesium solution, stock, 1 mL = 1000 µg of Mg

Dissolve 1.6584 g of MgO (element fraction Mg = 0.6030), accurately weighed to at least four significant figures, in a minimum amount of (1:1) HNO₃. Add 10.0 mL of (1:1) concentrated HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.16 Manganese solution, stock, 1 mL = 1000 µg of Mn

Dissolve 1.00 g of manganese metal, accurately weighed to at least four significant figures, in acid mixture (10 mL of concentrated HCl and 1 mL of concentrated HNO₃) and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.17 Mercury solution, stock, 1 mL = 1000 µg of Hg

WARNING: Do not dry, mercury is a highly toxic element.

Dissolve 1.354 g of HgCl₂ (Hg fraction = 0.7388) in reagent water. Add 50.0 mL of concentrated HNO₃ and dilute to volume in 1000-mL volumetric flask with reagent water.

7.3.18 Molybdenum solution, stock, 1 mL = 1000 µg of Mo

Dissolve 1.7325 g of (NH₄)₆Mo₇O₂₄·4H₂O (element fraction Mo = 0.5772), accurately weighed to at least four significant figures, in reagent water and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.19 Nickel solution, stock, 1 mL = 1000 µg of Ni

Dissolve 1.000 g of nickel metal, accurately weighed to at least four significant figures, in 10.0 mL of hot concentrated HNO₃, cool, and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.20 Phosphate solution, stock, 1 mL = 1000 µg of P

Dissolve 4.3937 g of anhydrous KH₂PO₄ (element fraction P = 0.2276), accurately weighed to at least four significant figures, in water. Dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.21 Potassium solution, stock, 1 mL = 1000 µg of K

Dissolve 1.9069 g of KCl (element fraction K = 0.5244) dried at 110 EC, accurately weighed to at least four significant figures, in reagent water, and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.22 Selenium solution, stock, 1 mL = 1000 µg of Se

Do not dry. Dissolve 1.6332 g of H_2SeO_3 (element fraction Se = 0.6123), accurately weighed to at least four significant figures, in reagent water and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.23 Silica solution, stock, 1 mL = 1000 µg SiO_2

Do not dry. Dissolve 2.964 g of NH_4SiF_6 , accurately weighed to at least four significant figures, in 200 mL (1:20) HCl with heating at 85 °C to dissolve the solid. Let solution cool and dilute to volume in a 1000-mL volumetric flask with reagent water. Store in a PTFE container and protect from light.

7.3.24 Silver solution, stock, 1 mL = 1000 µg of Ag

Dissolve 1.5748 g of AgNO_3 (element fraction Ag = 0.6350), accurately weighed to at least four significant figures, in water and 10 mL of concentrated HNO_3 . Dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.25 Sodium solution, stock, 1 mL = 1000 µg of Na

Dissolve 2.5419 g of NaCl (element fraction Na = 0.3934), accurately weighed to at least four significant figures, in reagent water. Add 10.0 mL of concentrated HNO_3 and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.26 Strontium solution, stock, 1 mL = 1000 µg of Sr

Dissolve 2.4154 g of strontium nitrate ($\text{Sr}(\text{NO}_3)_2$) (element fraction Sr = 0.4140), accurately weighed to at least four significant figures, in a 1000-mL flask containing 10 mL of concentrated HCl and 700 mL of reagent water. Dilute to volume with reagent water.

7.3.27 Thallium solution, stock, 1 mL = 1000 µg of Tl

Dissolve 1.3034 g of TlNO_3 (element fraction Tl = 0.7672), accurately weighed to at least four significant figures, in reagent water. Add 10.0 mL of concentrated HNO_3 and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.28 Tin solution, stock, 1 mL = 1000 µg of Sn

Dissolve 1.000 g of Sn shot, accurately weighed to at least 4 significant figures, in 200 mL of HCl (1:1) with heating to dissolve the metal. Let solution cool and dilute with HCl (1:1) in a 1000-mL volumetric flask.

7.3.29 Vanadium solution, stock, 1 mL = 1000 µg of V

Dissolve 2.2957 g of NH_4VO_3 (element fraction V = 0.4356), accurately weighed to at least four significant figures, in a minimum amount of concentrated HNO_3 . Heat to dissolve the metal. Add 10.0 mL of concentrated HNO_3 and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.30 Zinc solution, stock, 1 mL = 1000 µg of Zn

Dissolve 1.2447 g of ZnO (element fraction Zn = 0.8034), accurately weighed to at least four significant figures, in a minimum amount of dilute HNO₃. Add 10.0 mL of concentrated HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.3.31 Yttrium solution, stock, 1 mL = 1000 µg of Y

Dissolve 4.3081 g of Y(NO₃)₃·6H₂O (element fraction Y = 0.2321), accurately weighed to at least four significant figures, in a minimum amount of dilute HNO₃. Add 10.0 mL of concentrated HNO₃ and dilute to volume in a 1000-mL volumetric flask with reagent water.

7.4 Mixed calibration standard solutions

Prepare mixed calibration standard solutions (see Table 3) by combining appropriate volumes of the stock solutions above in volumetric flasks. Add the appropriate types and volumes of acids so that the standards are matrix-matched with the sample digestates. Prior to preparing the mixed standards, each stock solution should be analyzed separately to determine possible spectral interference or the presence of impurities. Care should be taken when preparing the mixed standards to ensure that the elements are compatible and stable together. Transfer the mixed standard solutions to FEP fluorocarbon or previously unused polyethylene or polypropylene bottles for storage. For all intermediate and working standards, especially low level standards (i.e., <1 ppm), stability must be demonstrated prior to use. Freshly-mixed standards should be prepared, as needed, with the realization that concentration can change with age. (Refer to Sec. 10.3.1 for guidance on determining the viability of standards.) Some typical calibration standard combinations are listed in Table 3.

NOTE: If the addition of silver to the recommended acid combination initially results in a precipitate, then add 15 mL of water and warm the flask until the solution clears. Cool and dilute to 100 mL with water. For this acid combination, the silver concentration should be limited to 2 mg/L. Silver is stable under these conditions in a water matrix for 30 days, if protected from the light. Higher concentrations of silver require additional HCl.

7.5 Blanks

Two types of blanks are required for the analysis of samples prepared by any method other than Method 3040. The calibration blank is used in establishing the analytical curve and the method blank is used to identify possible contamination resulting from either the reagents (acids) or the equipment used during sample processing including filtration.

7.5.1 The calibration blank is prepared by acidifying reagent water to the same concentrations of the acids found in the standards and samples. Prepare a sufficient quantity to flush the system between standards and samples. The calibration blank will also be used for all initial (ICB) and continuing calibration blank (CCB) determinations.

7.5.2 The method blank must contain all of the reagents in the same volumes as used in the processing of the samples. The method blank must be carried through the complete procedure and contain the same acid concentration in the final solution as the sample solution used for analysis (refer to Sec. 9.5).

7.6 The initial calibration verification (ICV) standard is prepared by the analyst (or a purchased second source reference material) by combining compatible elements from a

standard source different from that of the calibration standard, and at concentration near the midpoint of the calibration curve (see Sec. 10.3.3 for use). This standard may also be purchased.

7.7 The continuing calibration verification (CCV) standard should be prepared in the same acid matrix using the same standards used for calibration, at a concentration near the mid-point of the calibration curve (see Sec. 10.3.4 for use).

7.8 The interference check solution is prepared to contain known concentrations of interfering elements that will provide an adequate test of the correction factors. Spike the sample with the elements of interest, particularly those with known interferences at 0.5 to 1 mg/L. In the absence of measurable analyte, overcorrection could go undetected because a negative value could be reported as zero. If the particular instrument will display overcorrection as a negative number, this spiking procedure will not be necessary.

8.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

See the introductory material to Chapter Three, "Inorganic Analytes."

9.0 QUALITY CONTROL

9.1 Refer to Chapter One for additional guidance on quality assurance (QA) and quality control (QC) protocols. When inconsistencies exist between QC guidelines, method-specific QC criteria take precedence over both technique-specific criteria and those criteria given in Chapter One, and technique-specific QC criteria take precedence over the criteria in Chapter One. Any effort involving the collection of analytical data should include development of a structured and systematic planning document, such as a Quality Assurance Project Plan (QAPP) or a Sampling and Analysis Plan (SAP), which translates project objectives and specifications into directions for those that will implement the project and assess the results. Each laboratory should maintain a formal quality assurance program. The laboratory should also maintain records to document the quality of the data generated. All data sheets and quality control data should be maintained for reference or inspection.

9.2 Refer to the 3000 series method to be used (e.g., Method 3005, 3010, 3015, 3031, 3040, 3050, 3051, or 3052) for appropriate QC procedures to ensure the proper operation of the various sample preparation techniques.

9.3 Instrument detection limits (IDLs) are useful means to evaluate the instrument noise level and response changes over time for each analyte from a series of reagent blank analyses to obtain a calculated concentration. They are not to be confused with the lower limit of quantitation, nor should they be used in establishing this limit. It may be helpful to compare the calculated IDLs to the established lower limit of quantitation, however, it should be understood that the lower limit of quantitation needs to be verified according to the guidance in Sec. 10.0.

IDLs in $\mu\text{g/L}$ can be estimated by calculating the average of the standard deviations of three runs on three non-consecutive days from the analysis of a reagent blank solution with seven consecutive measurements per day. Each measurement should be performed as though it were a separate analytical sample (i.e., each measurement must be followed by a rinse and/or any other procedure normally performed between the analysis of separate samples). IDLs should be determined at least every three months or at a project-specific designated frequency and kept with the instrument log book.

9.4 Initial demonstration of proficiency

Each laboratory must demonstrate initial proficiency with each sample preparation (a 3000 series method) and determinative method combination it utilizes by generating data of acceptable accuracy and precision for target analytes in a clean matrix. If an autosampler is used to perform sample dilutions, before using the autosampler to dilute samples, the laboratory should satisfy itself that those dilutions are of equivalent or better accuracy than is achieved by an experienced analyst performing manual dilutions. The laboratory must also repeat the demonstration of proficiency whenever new staff members are trained or significant changes in instrumentation are made.

9.5 Dilute and reanalyze samples that exceed the linear dynamic range or use an alternate, less sensitive calibration for which quality control data are already established.

9.6 For each batch of samples processed, at least one method blank must be carried throughout the entire sample preparation and analytical process. A method blank is prepared by using a volume or weight of reagent water at the volume or weight specified in the preparation method, and then carried through the appropriate steps of the analytical process. These steps may include, but are not limited to, prefiltering, digestion, dilution, filtering, and analysis. If the method blank does not contain target analytes at a level that interferes with the project-specific DQOs, then the method blank would be considered acceptable.

In the absence of project-specific DQOs, if the blank is less than 10% of the lower limit of quantitation check sample concentration, less than 10% of the regulatory limit, or less than 10% of the lowest sample concentration for each analyte in a given preparation batch, whichever is greater, then the method blank is considered acceptable. If the method blank cannot be considered acceptable, the method blank should be re-run once, and if still unacceptable, then all samples after the last acceptable method blank should be reprepared and reanalyzed along with the other appropriate batch QC samples. These blanks will be useful in determining if samples are being contaminated. If the method blank exceeds the criteria, but the samples are all either below the reporting level or below the applicable action level or other DQOs, then the sample data may be used despite the contamination of the method blank.

9.7 Laboratory control sample (LCS)

For each batch of samples processed, at least one LCS must be carried throughout the entire sample preparation and analytical process. The laboratory control samples should be spiked with each analyte of interest at the project-specific action level or, when lacking project-specific action levels, at approximately mid-point of the linear dynamic range. Acceptance criteria should either be defined in the project-specific planning documents or set at a laboratory derived limit developed through the use of historical analyses. In the absence of project-specific or historical data generated criteria, this limit should be set at $\pm 20\%$ of the spiked value. Acceptance limits derived from historical data should be no wider than $\pm 20\%$. If the laboratory control sample is not acceptable, then the laboratory control sample should be re-run once and, if still unacceptable, all samples after the last acceptable laboratory control sample should be reprepared and reanalyzed.

Concurrent analyses of standard reference materials (SRMs) containing known amounts of analytes in the media of interest are recommended and may be used as an LCS. For solid SRMs, 80 -120% accuracy may not be achievable and the manufacturer's established acceptance criterion should be used for soil SRMs.

9.8 Matrix spike, unspiked duplicate, or matrix spike duplicate (MS/Dup or MS/MSD)

Documenting the effect of the matrix, for a given preparation batch consisting of similar sample characteristics, should include the analysis of at least one matrix spike and one duplicate unspiked sample or one matrix spike/matrix spike duplicate pair. The decision on whether to prepare and analyze duplicate samples or a matrix spike/matrix spike duplicate must be based on a knowledge of the samples in the sample batch or as noted in the project-specific planning documents. If samples are expected to contain target analytes, then laboratories may use one matrix spike and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes, laboratories should use a matrix spike and matrix spike duplicate pair.

For each batch of samples processed, at least one MS/Dup or MS/MSD sample set should be carried throughout the entire sample preparation and analytical process as described in Chapter One. MS/MSDs are intralaboratory split samples spiked with identical concentrations of each analyte of interest. The spiking occurs prior to sample preparation and analysis. An MS/Dup or MS/MSD is used to document the bias and precision of a method in a given sample matrix.

Refer to Chapter One for definitions of bias and precision, and for the proper data reduction protocols. MS/MSD samples should be spiked at the same level, and with the same spiking material, as the corresponding laboratory control sample that is at the project-specific action level or, when lacking project-specific action levels, at approximately mid-point of the linear dynamic range. Acceptance criteria should either be defined in the project-specific planning documents or set at a laboratory-derived limit developed through the use of historical analyses per matrix type analyzed. In the absence of project-specific or historical data generated criteria, these limits should be set at $\pm 25\%$ of the spiked value for accuracy and 20 relative percent difference (RPD) for precision. Acceptance limits derived from historical data should be no wider than $\pm 25\%$ for accuracy and 20% for precision. Refer to Chapter One for additional guidance. If the bias and precision indicators are outside the laboratory control limits, if the percent recovery is less than 75% or greater than 125%, or if the relative percent difference is greater than 20%, then the interference test discussed in Sec. 9.9 should be conducted.

9.8.1 The relative percent difference between spiked matrix duplicate or unspiked duplicate determinations is to be calculated as follows:

$$RPD = \frac{D_1 - D_2}{\left(\frac{D_1 + D_2}{2} \right)} \times 100$$

where:

RPD = relative percent difference.

D_1 = first sample value.

D_2 = second sample value (spiked or unspiked duplicate).

9.8.2 The spiked sample or spiked duplicate sample recovery should be within $\pm 25\%$ of the actual value, or within the documented historical acceptance limits for each matrix.

9.9 If less than acceptable accuracy and precision data are generated, additional quality control tests (Secs. 9.9.1 and 9.9.2) are recommended prior to reporting concentration data for the elements in this method. At a minimum, these tests should be performed with each batch of samples prepared/analyzed with corresponding unacceptable data quality results. These tests will then serve to ensure that neither positive nor negative interferences are affecting the measurement of any of the elements or distorting the accuracy of the reported values. If matrix effects are confirmed, the laboratory should consult with the data user when feasible for possible corrective actions which may include the use of alternative or modified test procedures so that the analysis is not impacted by the same interference.

9.9.1 Post digestion spike addition

If the MS/MSD recoveries are unacceptable, the same sample from which the MS/MSD aliquots were prepared should also be spiked with a post digestion spike. Otherwise, another sample from the same preparation should be used as an alternative. An analyte spike is added to a portion of a prepared sample, or its dilution, and should be recovered to within 80% to 120% of the known value. The spike addition should produce a minimum level of 10 times and a maximum of 100 times the lower limit of quantitation. If this spike fails, then the dilution test (Sec. 9.9.2) should be run on this sample. If both the MS/MSD and the post digestion spike fail, then matrix effects are confirmed.

9.9.2 Dilution test

If the analyte concentration is sufficiently high (minimally, a factor of 10 above the lower limit of quantitation after dilution), an analysis of a 1:5 dilution should agree within $\pm 10\%$ of the original determination. If not, then a chemical or physical interference effect should be suspected.

CAUTION: If spectral overlap is suspected, then the use of computerized compensation, an alternate wavelength, or comparison with an alternate method is recommended.

9.10 Ultra-trace analysis requires the use of clean chemistry preparation and analysis techniques. Several suggestions for minimizing analytical blank contamination are provided in Chapter Three.

10.0 CALIBRATION AND STANDARDIZATION

10.1 Set up the instrument with proper operating parameters established as detailed below. The instrument should be allowed to become thermally stable before beginning (usually requiring at least 30 minutes of operation prior to calibration). For operating conditions, the analyst should follow the instructions provided by the instrument manufacturer.

10.1.1 Before using this procedure to analyze samples, data should be available documenting the initial demonstration of performance. The required data should document the location of the background points being used for correction; the determination of the linear dynamic ranges; a demonstration of the desired method sensitivity and instrument detection limits; and the determination and verification of interelement correction equations or other routines for correcting spectral interferences. These data should be generated using the same instrument, operating conditions, and calibration routine to be used for sample analysis. These data should be kept on file and be available for review by the data user or auditor.

10.1.2 Sensitivity, instrumental detection limit, precision, linear dynamic range, and interference corrections need to be established for each individual target analyte on each particular instrument. All measurements (both target analytes and constituents which interfere with the target analytes) need to be within the instrument linear range where the correction equations are valid.

10.1.3 The lower limits of quantitation should be established for all wavelengths utilized for each type of matrix analyzed and for each preparation method used and for each instrument. These limits are considered the lowest reliable laboratory reporting concentrations and should be established from the lower limit of quantitation check sample and then confirmed using either the lowest calibration point or from a low-level calibration check standard.

10.1.3.1 Lower limit of quantitation check sample

The lower limit of quantitation check (LLQC) sample should be analyzed after establishing the lower laboratory reporting limits and on an as needed basis to demonstrate the desired detection capability. Ideally, this check sample and the low-level calibration verification standard will be prepared at the same concentrations with the only difference being the LLQC sample is carried through the entire preparation and analytical procedure. Lower limits of quantitation are verified when all analytes in the LLQC sample are detected within $\pm 30\%$ of their true value. This check should be used to both establish and confirm the lowest quantitation limit.

10.1.3.2 The lower limits of quantitation determination using reagent water represents a best case situation and does not represent possible matrix effects of real-world samples. For the application of lower limits of quantitation on a project-specific basis with established data quality objectives, low-level matrix-specific spike studies may provide data users with a more reliable indication of the actual method sensitivity and minimum detection capabilities.

10.1.4 Specific recommended wavelengths are listed in Table 1. Other wavelengths may be substituted if they can provide the needed sensitivity and are corrected for spectral interference. Because of differences among various makes and models of spectrometers, specific instrument operating conditions are not provided. The instrument and operating conditions utilized for determination must be capable of providing data of acceptable quality for the specific project and data user. The analyst should follow the instructions provided by the instrument manufacturer unless other conditions provide similar or better performance for a given task.

For radial viewed plasma, operating conditions for aqueous solutions usually vary from:

- C 1100 to 1200 watts forward power,
- C 14 to 18 mm viewing height,
- C 15 to 19 L/min argon coolant flow,
- C 0.6 to 1.5 L/min argon nebulizer flow,
- C 1 to 1.8 mL/min sample pumping rate with a 1 minute preflush time and measurement time near 1 sec per wavelength peak for sequential instruments and a rinse time of 10 sec per replicate with a 1 sec per replicate read time for simultaneous instruments.

For an axial viewed plasma, the conditions will usually vary from:

- C 1100 to 1500 watts forward power,
- C 15 to 19 L/min argon coolant flow,
- C 0.6 to 1.5 L/min argon nebulizer flow,
- C 1 to 1.8 mL/min sample pumping rate with a 1 minute preflush time and measurement time near 1 sec per wavelength peak for sequential instruments and a rinse time of 10 sec per replicate with a 1 sec per replicate read time for simultaneous instruments.

One recommended way to achieve repeatable interference correction factors is to adjust the argon aerosol flow to reproduce the Cu/Mn intensity ratio at 324.754 nm and 257.610 nm respectively. This can be performed before daily calibration and after the instrument warm-up period.

10.1.5 Plasma optimization

The plasma operating conditions need to be optimized prior to use of the instrument. The purpose of plasma optimization is to provide a maximum signal to background ratio for some of the least sensitive elements in the analytical array. The use of a mass flow controller to regulate the nebulizer gas flow or source optimization software greatly facilitates the procedure. This routine is not required on a daily basis, it is only required when first setting up a new instrument, or following a change in operating conditions. The following procedure is recommended, or follow the manufacturer's recommendations.

10.1.5.1 Ignite the radial plasma and select an appropriate incident radio frequency (RF) power. Allow the instrument to become thermally stable before beginning, about 30 to 60 minutes of operation. While aspirating a 1000 µg/L solution of yttrium, follow the instrument manufacturer's instructions and adjust the aerosol carrier gas flow rate through the nebulizer so a definitive blue emission region of the plasma extends approximately from 5 to 20 mm above the top of the load coil. Record the nebulizer gas flow rate or pressure setting for future reference. The yttrium solution can also be used for coarse optical alignment of the torch by observing the overlay of the blue light over the entrance slit to the optical system.

10.1.5.2 After establishing the nebulizer gas flow rate, determine the solution uptake rate of the nebulizer in mL/min by aspirating a known volume of a calibration blank for a period of at least three minutes. Divide the volume aspirated by the time in minutes and record the uptake rate. Set the peristaltic pump to deliver that rate in a steady even flow.

10.1.5.3 Profile the instrument to align it optically as it will be used during analysis. The following procedure is written for vertical optimization in the radial mode, but it also can be used for horizontal optimization.

Aspirate a solution containing 10 µg/L of several selected elements. As, Se, Tl, and Pb are the least sensitive of the elements and most in need of optimization. However, other elements may be used, based on the judgement of the analyst or project-specific protocols. (V, Cr, Cu, Li and Mn also have been used with success.) Collect intensity data at the wavelength peak for each analyte at 1 mm intervals from 14 to 18 mm above the load coil. (This region of the plasma is referred to as the analytical zone.) Repeat the process using the calibration blank. Determine the net signal to blank intensity ratio for each analyte for each viewing height setting. Choose the height for viewing the plasma that provides the

best net intensity ratios for the elements analyzed or the highest intensity ratio for the least sensitive element. For optimization in the axial mode, follow the instrument manufacturer's instructions.

10.1.5.4 The instrument operating conditions finally selected as being optimum should provide the most appropriate instrument responses that correlate to the desired target analyte sensitivity while meeting the minimum quality control criteria noted in this method or as specified in the project-specific planning documents.

10.1.5.5 If the instrument operating conditions, such as incident power or nebulizer gas flow rate, are changed, or if a new torch injector tube with a different orifice internal diameter is installed, then the plasma and viewing height should be re-optimized.

10.1.5.6 After completing the initial optimization of operating conditions, and before analyzing samples, the laboratory should establish and initially verify an interelement spectral interference correction routine to be used during sample analysis with interference check standards that closely match the anticipated properties of the expected sample matrices, i.e., for saltwater type matrices the interference check standard should contain components that match the salinities of the proposed sample matrix. A general description of spectral interferences and the analytical requirements for background correction, in particular, are discussed in Sec. 4.2.

10.1.5.7 Before daily calibration, and after the instrument warmup period, the nebulizer gas flow rate should be reset to the determined optimized flow. If a mass flow controller is being used, it should be set to the recorded optimized flow rate. In order to maintain valid spectral interelement correction routines, the nebulizer gas flow rate should be the same (< 2% change) from day to day.

10.2 For operation with organic solvents, the use of the auxiliary argon inlet is recommended, as is the use of solvent-resistant tubing, increased plasma (coolant) argon flow, decreased nebulizer flow, and increased RF power, to obtain stable operation and precise measurements.

10.3 All analyses require that a calibration curve be prepared to cover the appropriate concentration range based on the intended application and prior to establishing the linear dynamic range. Usually, this means the preparation of a calibration blank and mixed calibration standard solutions (Sec. 7.4), the highest of which would not exceed the anticipated linear dynamic range of the instrument. Check the instrument calibration by analyzing appropriate QC samples as follows.

10.3.1 Individual or mixed calibration standards should be prepared from known primary stock standards every six months to one year as needed based on the concentration stability as confirmed from the ICV analyses. The analysis of the ICV, which is prepared from a source independent of the calibration standards, is necessary to verify the instrument performance once the system has been calibrated for the desired target analytes. It is recommended that the ICV solution be obtained commercially as a certified traceable reference material such that an expiration date can be assigned. Alternately, the ICV solution can be prepared from an independent source on an as needed basis depending on the ability to meet the calibration verification criteria. If the ICV analysis is outside of the acceptance criteria, at a minimum the calibration standards must be

prepared fresh and the instrument recalibrated prior to beginning sample analyses. Consideration should also be given to preparing fresh ICV standards if the new calibration cannot be verified using the existing ICV standard.

NOTE: This method describes the use of both a low-level and mid-level ICV standard analysis. For purposes of verifying the initial calibration, only the mid-level ICV needs to be prepared from a source other than the calibration standards.

10.3.1.1 The calibration standards should be prepared using the same type of acid or combination of acids and at similar concentrations as will result in the samples following processing.

10.3.1.2 The response of the calibration blank should be less than the response of the typical laboratory lower limit of quantitation for each desired target analyte. Additionally, if the calibration blank response or continuing calibration blank verification is used to calculate a theoretical concentration, this value should be less than the level of acceptable blank contamination as specified in the approved quality assurance project planning documents. If this is not the case, the reason for the out-of-control condition must be found and corrected, and the sample analyses should not proceed or the previous ten samples should be reanalyzed.

10.3.2 For the initial and daily instrument operation, calibrate the system according to the instrument manufacturer's guidelines using the mixed calibration standards as noted in Sec. 7.4. The calibration curve should be prepared daily with a minimum of a calibration blank and a single standard at the appropriate concentration to effectively outline the desired quantitation range. The resulting curve should then be verified with mid-level and low-level initial calibration verification standards as outlined in Sec. 10.3.3.

Alternatively, the calibration curve can be prepared daily with a minimum of a calibration blank and three non-zero standards that effectively bracket the desired sample concentration range. If low-level as compared to mid- or high-level sample concentrations are expected, the calibration standards should be prepared at the appropriate concentrations in order to demonstrate the instrument linearity within the anticipated sample concentration range. For all multi-point calibration scenarios, the lowest non-zero standard concentration should be considered the lower limit of quantitation.

NOTE: Regardless of whether the instrument is calibrated using only a minimum number of standards or with a multi-point curve, the upper limit of the quantitation range may exceed the highest concentration calibration point and can be defined as the "linear dynamic" range, while the lower limit can be identified as the "lower limit of quantitation limit" (LLQL) and will be either the concentration of the lowest calibration standard (for multi-point curves) or the concentration of the low level ICV/CCV check standard. Results reported outside these limits would not be recommended unless they are qualified as estimated. See Sec. 10.4 for recommendations on how to determine the linear dynamic range. The guidance in this section and Sec. 10.3.3 provide options for defining the lower limit of quantitation.

10.3.2.1 To be considered acceptable, the calibration curve should have a correlation coefficient greater than or equal to 0.998. When using a multi-point calibration curve approach, every effort should be made to attain an acceptable correlation coefficient based on a linear response for each desired

target analyte. If the recommended linear response cannot be attained using a minimum of three non-zero calibration standards, consideration should be given to adding more standards, particularly at the lower concentrations, in order to better define the linear range and the lower limit of quantitation. Conversely, the extreme upper and lower calibration points may be removed from the multi-point curve as long as three non-zero points remain such that the linear range is narrowed and the non-linear upper and/or lower portions are removed. As with the single point calibration option, the multi-point calibration should be verified with both a mid- and low-level ICV standard analysis using the same 90 - 110% and 70 - 130% acceptance criteria, respectively.

10.3.2.2 Many instrument software packages allow multi-point calibration curves to be "forced" through zero. It is acceptable to use this feature, provided that the resulting calibration meets the acceptance criteria, and can be verified by acceptable QC results. Forcing a regression through zero should NOT be used as a rationale for reporting results below the calibration range defined by the lowest standard in the calibration curve.

10.3.3 After initial calibration, the calibration curve should be verified by use of an initial calibration verification (ICV) standard analysis. At a minimum, the ICV standard should be prepared from an independent (second source) material at or near the mid-range of the calibration curve. The acceptance criteria for this mid-range ICV standard should be $\pm 10\%$ of its true value. Additionally, a low-level initial calibration verification (LLICV) standard should be prepared, using the same source as the calibration standards, at a concentration expected to be the lower limit of quantitation. The suggested acceptance criteria for the LLICV is $\pm 30\%$ of its true value. Quantitative sample analyses should not proceed for those analytes that fail the second source standard initial calibration verification. However, analyses may continue for those analytes that fail the criteria with an understanding these results should be qualified and would be considered estimated values. Once the calibration acceptance criteria is met, either the lowest calibration standard or the LLICV concentration can be used to demonstrate the lower limit of quantitation and sample results should not be quantitated below this lowest standard. In some cases depending on the stated project data quality objectives, it may be appropriate to report these results as estimated, however, they should be qualified by noting the results are below the lower limit of quantitation. Therefore, the laboratory's quantitation limit cannot be reported lower than either the LLICV standard used for the single point calibration option or the low calibration and/or verification standard used during initial multi-point calibration. If the calibration curve cannot be verified within these specified limits for the mid-range ICV and LLICV analyses, the cause needs to be determined and the instrument recalibrated before samples are analyzed. The analysis data for the initial calibration verification analyses should be kept on file with the sample analysis data.

10.3.4 Both the single and multi-point calibration curves should be verified at the end of each analysis batch and after every 10 samples by use of a continuing calibration verification (CCV) standard and a continuing calibration blank (CCB). The CCV should be made from the same material as the initial calibration standards at or near the mid-range concentration. For the curve to be considered valid, the acceptance criteria for the CCV standard should be $\pm 10\%$ of its true value and the CCB should contain target analytes less than the established lower limit of quantitation for any desired target analyte. If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the cause determined and the instrument recalibrated. All samples following the last acceptable CCV/CCB must be reanalyzed. The analysis data for the CCV/CCB should be kept on file with the sample analysis data.

The low-level continuing calibration verification (LLCCV) standard should also be analyzed at the end of each analysis batch. A more frequent LLCCV analysis, i.e., every 10 samples, may be necessary if low-level sample concentrations are anticipated and the system stability at low end of the calibration is questionable. In addition, the analysis of a LLCCV on a more frequent basis will minimize the number of samples for re-analysis should the LLCCV fail if only run at the end of the analysis batch. The LLCCV standard should be made from the same source as the initial calibration standards at the established lower limit of quantitation as reported by the laboratory. The acceptance criteria for the LLCCV standard should be $\pm 30\%$ of its true value. If the calibration cannot be verified within these specified limits, the analysis of samples containing the affected analytes at similar concentrations cannot continue until the cause is determined and the LLCCV standard successfully analyzed. The instrument may need to be recalibrated or the lower limit of quantitation adjusted to a concentration that will ensure a compliant LLCCV analysis. The analysis data for the LLCCV standard should be kept on file with the sample analysis data.

10.4 The linear dynamic range is established when the system is first setup, or whenever significant instrument components have been replaced or repaired, and on an as needed basis only after the system has been successfully calibrated using either the single or multi-point standard calibration approach.

The upper limit of the linear dynamic range needs to be established for each wavelength utilized by determining the signal responses from a minimum of three, preferably five, different concentration standards across the range. The ranges which may be used for the analysis of samples should be judged by the analyst from the resulting data. The data, calculations and rationale for the choice of range made should be documented and kept on file. A standard at the upper limit should be prepared, analyzed and quantitated against the normal calibration curve. The calculated value should be within 10% ($\pm 10\%$) of the true value. New upper range limits should be determined whenever there is a significant change in instrument response. At a minimum, the range should be checked every six months. The analyst should be aware that if an analyte that is present above its upper range limit is used to apply an interelement correction, the correction may not be valid and those analytes where the interelement correction has been applied may be inaccurately reported.

NOTE: Many of the alkali and alkaline earth metals have non-linear response curves due to ionization and self-absorption effects. These curves may be used if the instrument allows it; however the effective range must be checked and the second order curve fit should have a correlation coefficient of 0.998 or better. Third order fits are not acceptable. These non-linear response curves should be revalidated and/or recalculated on a daily basis using the same calibration verification QC checks as a linear calibration curve. Since these curves are much more sensitive to changes in operating conditions than the linear lines, they should be checked whenever there have been moderate equipment changes. Under these calibration conditions, quantitation is not acceptable above or below the calibration standards. Additionally, a non-linear curve should be further verified by calculating the actual recovery of each calibration standard used in the curve. The acceptance criteria for the calibration standard recovery should be $\pm 10\%$ of its true value for all standards except the lowest concentration. A recovery of $\pm 30\%$ of its true value should be achieved for the lowest concentration standard.

10.5 The analyst should (1) verify that the instrument configuration and operating conditions satisfy the project-specific analytical requirements and (2) maintain quality control data that demonstrate and confirm the instrument performance for the reported analytical results.

11.0 PROCEDURE

11.1 Preliminary treatment of most matrices is necessary because of the complexity and variability of sample matrices. Groundwater and other aqueous samples designated for a dissolved metal determination which have been prefiltered and acidified will not need acid digestion. However, all associated QC samples (i.e., method blank, LCS and MS/MSD) must undergo the same filtration and acidification procedures. Samples which are not digested must either use an internal standard or be matrix-matched with the standards. Solubilization and digestion procedures are presented in Chapter Three, "Inorganic Analytes."

11.2 Profile and calibrate the instrument according to the instrument manufacturer's recommended procedures, using the typical mixed calibration standard solutions described in Sec. 7.4. Flush the system with the calibration blank (Sec. 7.5.1) between each standard or as the manufacturer recommends. (Use the average intensity of multiple exposures for both standardization and sample analysis to reduce random error.) The calibration curve should be prepared as detailed in Sec. 10.3.2.

11.3 Regardless of whether the initial calibration is performed using a single high standard and the calibration blank or the multi-point option, the laboratory should analyze an LLCCV (Sec. 10.3.4). For all analytes and determinations, the laboratory must analyze an ICV and LLICV (Sec. 10.3.3) immediately following daily calibration. It is recommended that a CCV LLCCV, and CCB (Sec. 10.3.4) be analyzed after every ten samples and at the end of the analysis batch.

11.4 Rinse the system with the calibration blank solution (Sec. 7.5.1) before the analysis of each sample. The rinse time will be one minute. Each laboratory may establish a reduction in this rinse time through a suitable demonstration. Analyze the samples and record the results.

12.0 DATA ANALYSIS AND CALCULATIONS

12.1 The quantitative values must be reported in appropriate units, such as micrograms per liter ($\mu\text{g/L}$) for aqueous samples and milligrams per kilogram (mg/kg) for solid samples. If dilutions were performed, the appropriate corrections must be applied to the sample values. All results should be reported with up to three significant figures.

12.2 If appropriate, or required, calculate results for solids on a dry-weight basis as follows:

- (1) A separate determination of percent solids must be performed.
- (2) The concentrations determined in the digest are to be reported on the basis of the dry weight of the sample.

$$\text{Concentration (dry weight)(mg/kg)} = \frac{C \times V}{W \times S}$$

Where,

C = Digest Concentration (mg/L)

V = Final volume in liters after sample preparation

W = Weight in kg of wet sample

$$S = \frac{\% \text{ Solids}}{100}$$

Calculations must include appropriate interference corrections (see Sec. 4.2 for examples), internal-standard normalization, and the summation of signals at 206, 207, and 208 m/z for lead (to compensate for any differences in the abundances of these isotopes between samples and standards).

12.3 Results must be reported in units commensurate with their intended use and all dilutions must be taken into account when computing final results.

13.0 METHOD PERFORMANCE

13.1 Performance data and related information are provided in SW-846 methods only as examples and guidance. The data do not represent required performance criteria for users of the methods. Instead, performance criteria should be developed on a project-specific basis, and the laboratory should establish in-house QC performance criteria for the application of this method. These performance data are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

13.2 In an EPA round-robin study, seven laboratories applied the ICP technique to acid-digested water matrices that had been spiked with various metal concentrates. Table 4 lists the true values, the mean reported values, and the mean percent relative standard deviations. These data are provided for guidance purposes only.

13.3 Performance data for aqueous solutions and solid samples from a multilaboratory study are provided in Tables 5 and 6. These data are provided for guidance purposes only.

14.0 POLLUTION PREVENTION

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity and/or toxicity of waste at the point of generation. Numerous opportunities for pollution prevention exist in laboratory operation. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.

14.2 For information about pollution prevention that may be applicable to laboratories and research institutions consult *Less is Better: Laboratory Chemical Management for Waste*

15.0 WASTE MANAGEMENT

The Environmental Protection Agency requires that laboratory waste management practices be conducted consistent with all applicable rules and regulations. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods and bench operations, complying with the letter and spirit of any sewer discharge permits and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management, consult *The Waste Management Manual for Laboratory Personnel* available from the American Chemical Society at the address listed in Sec. 14.2.

TABLE 1
(continued)

- ^a The wavelengths listed (where x2 indicates second order) are recommended because of their sensitivity. Other wavelengths may be substituted (e.g., in the case of an interference) if they provide the needed sensitivity and are treated with the same corrective techniques for spectral interference.
- ^b The estimated instrumental detection limits shown are provided for illustrative purposes only. Each laboratory must determine IDLs and MDLs, as necessary, for their specific application of the method. These IDLs represent radial plasma data and axial plasma IDLs may be lower.
- ^c Highly dependent on operating conditions and plasma position.

TABLE 2

POTENTIAL INTERFERENCES AND ANALYTE CONCENTRATION EQUIVALENTS (mg/L)
ARISING FROM INTERFERENCE AT THE 100-mg/L LEVEL

Vanadium	292.402	--	--	0.05	--	0.005	--	--	--	0.02	--
Zinc	213.856	--	--	--	0.14	--	--	--	0.29	--	--

^a Dashes indicate that no interference was observed even when interferents were introduced at the following levels:

Al at 1000 mg/L	Cu at 200 mg/L	Mn at 200 mg/L
Ca at 1000 mg/L	Fe at 1000 mg/L	Ti at 200 mg/L
Cr at 200 mg/L	Mg at 1000 mg/L	V at 200 mg/L

^b The data shown above as analyte concentration equivalents are not the actual observed concentrations. To obtain those data, add the listed concentration to the interferant figure.

^c Interferences will be affected by background choice and other interferences may be present.

TABLE 3
MIXED STANDARD SOLUTIONS

Solution	Elements
I	Be, Cd, Mn, Pb, Se and Zn
II	Ba, Co, Cu, Fe, and V
III	As and Mo
IV	Al, Ca, Cr, K, Na, Ni, Li, and Sr
V	Ag ^a , Mg, Sb, and Tl
VI	P

Se ^c	40	32	21.9	80	6	8.5	42	142	10	8.5	8.3	85

These data are provided for guidance purposes only.

^a Not all elements were analyzed by all laboratories.

^b RSD = relative standard deviation.

^c Results for Se are from two laboratories.

^d Accuracy is expressed as the mean concentration divided by the true concentration times 100.

TABLE 5

EXAMPLE ICP-AES PRECISION AND ACCURACY FOR AQUEOUS SOLUTIONS

Element	Mean Conc. (mg/L)	n	RSD (%)	Accuracy (%)
Al	14.8	8	6.3	100
Sb	15.1	8	7.7	102
As	14.7	7	6.4	99
Ba	3.66	7	3.1	99
Be	3.78	8	5.8	102
Cd	3.61	8	7.0	97
Ca	15.0	8	7.4	101
Cr	3.75	8	8.2	101
Co	3.52	8	5.9	95
Cu	3.58	8	5.6	97
Fe	14.8	8	5.9	100
Pb	14.4	7	5.9	97
Mg	14.1	8	6.5	96
Mn	3.70	8	4.3	100
Mo	3.70	8	6.9	100
Ni	3.70	7	5.7	100
K	14.1	8	6.6	95
Se	15.3	8	7.5	104
Ag	3.69	6	9.1	100
Na	14.0	8	4.2	95
Tl	15.1	7	8.5	102
V	3.51	8	6.6	95
Zn	3.57	8	8.3	96

These performance values are independent of sample preparation because the labs analyzed portions of the same solutions and are provided for illustrative purposes only.

n= Number of measurements.

Accuracy is expressed as a percentage of the nominal value for each analyte in acidified, multi-element solutions.

These data are provided for guidance purposes only.

TABLE 6

Revision Log	Formatting requirement per 1-P-QM-QMA-9017356	Removed revision logs up to the previous version
Cross Reference	Reflect current procedure	Added reference Analysis #6142, 6123, 6125, 10801...
Scope	Clarification	Reworded section.
Sample Collection, Preservation and Handling	Reflect current procedure	Changed sample storage temperature to 0° to 6°C, but not frozen.
Reagents and Standards	Reflect current procedure	Added reference to 1-P-QM-FOR-9009182.
Procedure	Reflect current procedure	Add boiling stones to the batch blank and LCS for the fish samples.
Block Digester Instructions	Reflect current procedure No longer used	Hold and press the star key. Deleted test pertaining to the control panel grey buttons.
Quality Assurance/Quality Control	Reflect current procedure	Added reference to ICP/MS Analysis #6142, 6123, 6125, 10801, for batch requirements.

Revision: 20		Effective Date: Jan 22, 2013
Section	Justification	Changes
Revision Log	Formatting requirement per 1-P-QM-QMA-9017356	Removed revision logs up to the previous version
Throughout Document	Reflect re-identification of documents in EtQ	Replaced all prior Level 1, 2, 3, and 4 document numbers (analyses excluded) with EDR numbers
Safety Precautions and Waste Handling	Reflect current procedure	Added the use of designated dispensing equipment for HNO3 and HCL Added test pertaining to hazardous flags
Procedure	Reflects current procedure	Removed paint chip section. Deleted text pertaining to reducing the weight of paint chips. Paint chips will be digested as normal digestion per this procedure.
Procedure 2	Reflects current procedure	Added text pertaining to adding PTFE boiling stones to the LCS. Added text pertaining to entering the weights of the Blank and LCS in the LLENS.

1-P-QM-FOR-9009182	Working Instructions for Prep Solutions and Standards

Purpose:

This digestion procedure is for the preparation of solid samples for analysis by ICP and ICP/MS following SW-846 protocol.

Scope:

This method is used for preparation of metals in solid samples for analysis by ICP and ICP/MS.

Basic Principles:

A representative sample is digested with repeated additions of nitric acid (HNO₃) and hydrogen peroxide (H₂O₂). Hydrochloric acid (HCl) is added to the initial digestate and the sample is refluxed. The resultant digestate is diluted and analyzed.

--	---	--

This method is not a total digestion technique for most samples; it is a very strong acid digestion that dissolves almost all elements that could become “environmentally available.” By design, elements bound in silicate structures are not normally dissolved by this procedure.

Definitions:

1. ACS – American Chemical Society
2. D – Sample Duplicate
3. DOC – Demonstration of Capability
4. IDOC – Initial Demonstration of Capability
5. LCS/LCSD – Laboratory Control Sample/ Laboratory Control Sample Duplicate
6. LCSW– Laboratory Control Sample Water
7. LLENS - the computer program that integrates a PC with an analytical balance to collect data directly from the balance. The program organizes the data and transmits the readings to the LIMS.
8. LIMS – Laboratory Information Management Systems
9. LLI Sample ID – unique 7-digit number assigned to a client sample.
10. LOQ – Limit of Quantitation
11. MDL – Method Detection Limit
12. MS (R) – Matrix Spike
13. MSD (M) – Matrix spike duplicate

---	---	--

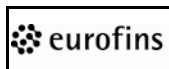

14. PB/PBW–Preparation Blank/ Preparation Blank Water
15. QC – Quality Control
16. Method Blank - equivalent to a Preparation Blank. A designated sample designed to monitor for sample contamination during the analysis process. A volume of reagent laboratory water is typically used to monitor water sample analysis, while solids blanks consist of a purified solid matrix or just the reagents used in the test. The blank demonstrates that no artifacts were introduced during the analysis process.
17. SOP- Standard Operating Procedure
18. U or US – unspiked background sample

Interferences:

When analyzing sample by ICP-MS using this digestion procedure we follow the instrument manufacturer’s guidelines to eliminate polyatomic interferences typically caused by Chlorine. The process we follow involves the use of a collision/reaction cell on the ICP-MS. Below is a description of how the collision/reaction cell works.

Reaction Process - The primary method of interference removal is through a reaction event. When using a reaction gas, either the target interference is more reactive than the target analyte, leading to preferential removal of the interferent or (less commonly) the target analyte is more reactive and is converted to a new species at a different mass which is free from any existing or newly-formed overlap

Collision Process - The primary method of interference removal is through a non-reactive event. This process of interference removal is kinetic energy discrimination (KED). Energy Discrimination is most commonly used with an inert gas, which means the interference removal process is not affected by reactions in the cell.

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
---	---	--

Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Preparing samples for inorganic analysis involves working with concentrated acids and other chemicals which are dangerous if not handled carefully:

Nitric acid (HNO₃) – This acid can cause skin burns. Add nitric acid to samples in a hood or use the designated dispensing equipment to avoid exposure to toxic fumes.

Hydrochloric acid (HCl) – This acid can cause skin burns. Never mix HCl with concentrated H₂SO₄ to avoid a violent reaction. Always use in a fume hood or use the designated dispensing equipment.

Hydrogen peroxide (H₂O₂) - This is a strong oxidizing agent and causes severe burns. Avoid contact with skin.

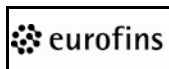

When diluting strong acids, never add water to acid; always add acid to water.

Store concentrated acids in the prep room acid lockers. Only acids are to be stored in these lockers. (Store solvents in the flammable liquid storage cabinet.) Some concentrated acids are kept in the acid reagent bottles on prep room counters. Fill reagent bottles in an operating fume hood using caution to avoid spills.

Perform acid digestions in hoods that are turned on and have active alarms. Notify a supervisor immediately if the hood is malfunctioning or the alarm sounds.

Samples that contain dust may be hazardous. Open in a fume hood.

Revision: 21	Effective date: Mar 17, 2014	Page 6 of 13
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
---	--	--

When a hazardous flag is added indicating possible cyanide, special precautions are required to avoid exposure to hydrogen cyanide gas. Contact your supervisor prior to adding acid. Always open these samples and add the acid in a hood.

Use spill pillows to absorb large acid spills (small spills are cleaned with wet paper towels.) Use SPILL-X-A powder or equivalent to neutralize any remaining acid and then rinse the area thoroughly with water. Spill pillows and SPILL-X-A are stored on the prep room shelf.

Dispose of acid waste properly. Collect all acid digestions, waste solutions, and expired reagent solutions in waste containers. When the acid waste containers are full, a designated acid waste handler transfers the waste to the acid neutralization tank.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability (DOC).

Initially, each employee performing this digestion procedure must work with an experienced employee for a period of time until they can independently set up batches and perform the necessary steps outlined in this procedure. Proficiency is measured through documentation of the critical steps in this procedure, over checking of data as well as an IDOC.

The IDOC and the DOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation.

Sample Collection, Preservation, and Handling:

Solid samples require no chemical preservation.

Samples must be submitted in glass or plastic containers and stored at 0° to 6°C, but not frozen, prior to digestion. Samples must be digested within 6 months (180 days) of sample collection.

--	---	--

Digested samples are stored in polypropylene bottles at room temperature.

Apparatus and Equipment:

1. Polypropylene containers and covers (digestion vessels) - certified clean and Class A equivalent
2. Whatman No. 41 filter paper or equivalent
3. Funnels
4. Environmental Express HotBlock (block digester) - adjustable and capable of maintaining a temperature of 90 to 95°C
5. Balance capable of reading 0.01 g
6. Chemware Ultra-Pure PTFE boiling stones, or equivalent.
7. Computer and software LLENS (Lancaster Laboratories Electronic Notebook System)

Reagents and Standards:

For reagent preparation, shelf life, and storage conditions, see Form 1-P-QM-FOR-9009182.

1. Nitric acid (HNO₃) – Fisher, Trace Metal Grade, or equivalent. Store at room temperature. Re-evaluate annually.
2. Nitric acid (1:1) – Add 500 mL of HNO₃ to 500 mL of reagent water. Store in polypropylene at room temperature. Expires 6 months from date of preparation. (Different volumes are acceptable but ratios must stay the same.)

Revision: 21	Effective date: Mar 17, 2014	Page 8 of 13
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
--	---	--

3. Hydrogen peroxide, 30% (H₂O₂) – Fisher, Certified ACS or equivalent. Store at room temperature. Re-evaluate annually.
4. Hydrochloric acid (HCl) – Baker Instra-Analyzed, or equivalent. Store at room temperature. Re-evaluate annually.

NOTE: It is acceptable to prepare using multiples of indicated weights and volumes if ratios are maintained.

Calibration:

Not applicable.

Procedure:

1. Turn block digestor on and allow block to reach the Control Point setting that provides 90° to 95°C sample temperature. (The block temperature setting is not necessarily the sample temperature.) See below for **Block Digestor Instructions** section.
2. Weigh 1.00 to 1.05 g (to the nearest 0.01 g) of a well mixed sample into a polypropylene digestion vessel. (If the sample is watery use 5.00 to 5.05 grams for analysis. Additional information on non-standard matrices is found at the end of the procedure section.) Add 1.00 to 1.49 g of Chemware Ultra-Pure PTFE boiling stones to the digestion vessel for the blank and LCS. Enter the blank and LCS weight as 1.0000 to 100.0000 final volume in the LLENS. For sample batch spiking procedures see 1-P-QM-FOR-9009182. All spiking must be performed prior to starting the digestion procedure.
3. Add 10 mL of (1:1) HNO₃, swirl to mix, and cover with a polypropylene cover.
4. Place sample vessel in block digestor. Heat (reflux) the sample at 90° to 95°C for 10 to 15 minutes without boiling.
5. Remove vessel from digestion block and allow sample to cool.

Revision: 21	Effective date: Mar 17, 2014	Page 9 of 13
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
--	---	--

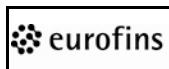

6. Add 5 mL of concentrated HNO₃. Replace cover, return vessel to digestion block and heat for 30 minutes.

NOTE: If brown fumes are generated (indicating oxidation of the sample by HNO₃) continue the process of adding 5 mL HNO₃ and heating until no brown fumes are given off by the sample. This indicates that the reaction with HNO₃ is complete. Add the same amount of HNO₃ to the entire digestion batch.

7. With cover on, heat at 90° to 95°C without boiling for 2 hours. Maintain a covering of solution over the bottom of the vessel at all times (add reagent water if necessary).
8. Remove vessel from digestion block and allow sample to cool.
9. Add 2 mL of reagent water and 3 mL of 30% H₂O₂. With cover on, return vessel to digestion block and heat until effervescence subsides. Care must be taken to ensure that losses do not occur due to excessively vigorous effervescence.
10. Continue to add 30% H₂O₂ in 1-mL aliquots with warming until the effervescence is minimal or until the general sample appearance is unchanged.

NOTE: Do not add more than a total of 10 mL 30% H₂O₂.

11. With cover on, continue heating the acid-peroxide digestate at 90° to 95°C without boiling for 2 hours. Maintain a covering of solution over the bottom of the vessel at all times (add reagent water if necessary).
12. Remove sample vessel from digestion block and allow to cool.
13. Add 10 mL of HCl. With the cover on, return vessel to digestion block and heat at 90° to 95°C for 15 minutes.

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
---	---	--

14. Remove sample vessel from digestion block.

15. If floating particulate is evident after digestion, the sample must be filtered.
 - a. Filter through Whatman No. 41 filter paper into a polypropylene container.

 - b. Wash sample vessel, residue, and paper thoroughly with reagent water.

 - c. If any samples are filtered, the prep blank and LCS must also be filtered.

16. Adjust volume to the 100mL mark on the digestion vessel with reagent water and mix. Seal vessel with a screw cap. The sample is now ready for analysis.

NOTE: When special limits of quantitation are required by the client, use more sample weight.

For wipe samples:

When wipes are digested by this method, one blank media each must be used for the batch preparation blank, the laboratory control sample (LCS), and the laboratory control sample duplicate (LCSD). Refer to Form 1-P-QM-FOR-9009182 for the spiking of the LCS and LCSD. Digest wipes in their own batch. Use reagent water to rinse any particulate matter from the wipe container into the vessel containing the wipe before digesting. If brown fumes are evolved during wipe sample digestion, perform only two 5 mL HNO₃ additions with 30-minute refluxing each; add the same amount of HNO₃ to the entire batch. Proceed with digestion.

For fish tissue samples:

When fish tissues are digested by this method, refer to Form 1-P-QM-FOR-9009182 for the spiking of the LCS, LCSD (if needed), R (matrix spike), and M (matrix spike duplicate). Add 1.00 to 1.49 g of Chemware Ultra-Pure PTFE boiling stones to the digestion vessel for the blank and LCS. Digest fish tissues in their own batch.

--	---	--

Block Digester Instructions:

1. Turn block digester on by pressing rocker switch located on the cord.
2. Wait about 8 seconds until controller display indicates current block temperature.
3. PRESS and hold STAR (*) key.
4. The display shows Control Point temperature.
5. The digits can be changed to the desired value by pressing the up and down arrow keys while holding the (*) key.
6. Confirm Control Point temperature is set to the block temperature that provides 90° to 95°C.

NOTE: See HotBlock Control Point Temperature Logbook to obtain control point temperature setting for the HotBlock being used. If necessary, adjust Control Point temperature to the proper setting as instructed below.

NOTE: Polypropylene containers must not be heated above 130°C.

Calculations:

Not applicable

Statistical Information/Method Performance:

Not applicable to this procedure. See analysis method.

Quality Assurance/Quality Control:

For sample batch spiking instructions see form 1-P-QM-FOR-9009182. Refer to ICP section when prepping ICP analysis. Refer to ICP/MS section when prepping ICP/MS analysis. Prepare a method blank, sample duplicate, sample matrix spike, sample matrix spike duplicate, and laboratory control sample with every digestion batch (20 samples or less). Each piece of batch QC is digested following the procedure in this SOP. If any samples are filtered the prep blank and LCS must also be filtered.

Refer to ICP Analysis #6966, 1643, 6935, ... for sample batch quality control requirements, acceptance criteria and corrective action.

Refer to ICP/MS Analysis #6142, 6123, 6125, 10801, 6126, ... for sample batch quality control requirements, acceptance criteria and corrective action.

GEL-PERMEATION CLEANUP

1.0 SCOPE AND APPLICATION

1.1 Gel-permeation chromatography (GPC) is a size exclusion cleanup procedure using organic solvents and hydrophobic gels in the separation of synthetic macromolecules (1). The packing gel is porous and is characterized by the range or uniformity (exclusion range) of that pore size. In the choice of gels, the exclusion range must be larger than the molecular size of the molecules to be separated (2). A cross-linked divinylbenzene-styrene copolymer (SX-3 Bio Beads or equivalent) is specified for this method.

1.2 General cleanup application - GPC is recommended for the elimination from the sample of lipids, polymers, copolymers, proteins, natural resins and polymers, cellular components, viruses, steroids, and dispersed high-molecular-weight compounds (2). GPC is appropriate for both polar and non-polar analytes, therefore, it can be effectively used to cleanup extracts containing a broad range of analytes.

1.3 Specific application - This method includes guidance for cleanup of sample extracts containing the following analytes from the RCRA Appendix VIII and Appendix IX lists:

Compound Name	CAS No. ^a

^a Chemical Abstract Services Registry Number.

Table 1 presents average percent recovery and percent RSD data for these analytes, as well as the retention volumes of each analyte on a single GPC system. Retention volumes vary from column to column. Figure 1 provides additional information on retention volumes for certain classes of compounds. The data for the semivolatiles were determined by GC/MS, whereas, the pesticide data were determined by GC/ECD or GC/FPD. Compounds not amenable to GC were determined by HPLC. Other analytes may also be appropriate for this cleanup technique, however, recovery through the GPC should be >70%.

1.4 Normally, this method is most efficient for removing high boiling materials that condense in the injection port area of a gas chromatograph (GC) or the front of the GC column. This residue will ultimately reduce the chromatographic separation efficiency or column capacity because of adsorption of the target analytes on the active sites. Pentachlorophenol is especially susceptible to this problem. GPC, operating on the principal of size exclusion, will not usually remove interference peaks that appear in the chromatogram since the molecular size of these compounds is relative similar to the target analytes. Separation cleanup techniques, based on other molecular characteristics (i.e., polarity), must be used to eliminate this type of interference.

2.0 SUMMARY OF METHOD

2.1 The column is packed with the required amount of preswelled absorbent, and is flushed with solvent for an extended period. The column is calibrated and then loaded with the sample extract to be cleaned up. Elution is effected with a suitable solvent(s) and the product is then concentrated.

3.0 INTERFERENCES

3.1 A reagent blank should be analyzed for the compound of interest prior to the use of this method. The level of interferences must be below the estimated quantitation limits (EQLs) of the analytes of interest before this method is performed on actual samples.

3.2 More extensive procedures than those outlined in this method may be necessary for reagent purification.

4.0 APPARATUS

4.1 Gel-permeation chromatography system - GPC Autoprep Model 1002 A or B, or equivalent, Analytical Biochemical Laboratories, Inc. Systems that perform very satisfactorily have also been assembled from the following components - an HPLC pump, an auto sampler or a valving system with sample loops, and a fraction collector. All systems, whether automated or manual, must meet the calibration requirements of Sec. 7.2.2.

4.1.1 Chromatographic column - 700 mm x 25 mm ID glass column. Flow is upward. (Optional) To simplify switching from the UV detector during calibration to the GPC collection device during extract cleanup, attach a double 3-way valve (Rheodyne Type 50 Teflon Rotary Valve #10-262 or equivalent) so that the column exit flow can be shunted either to the UV flow-through cell or to the GPC collection device.

4.1.2 Guard column - (Optional) 5 cm, with appropriate fittings to connect to the inlet side of the analytical column (Supelco 5-8319 or equivalent).

4.1.3 Bio Beads (S-X3) - 200-400 mesh, 70 g (Bio-Rad Laboratories, Richmond, CA, Catalog 152-2750 or equivalent). An additional 5 g of Bio Beads are required if the optional guard column is employed. The quality of Bio Beads may vary from lot to lot because of excessive fines in some lots. The UV chromatogram of the Calibration solution should be very similar to that in Figure 2, and the backpressure should be within 6-10 psi. Also, the gel swell ratio in methylene chloride should be in the range of 4.4 - 4.8 mL/g. In addition to fines having a detrimental effect on chromatography, they can also pass through the column screens and damage the valve.

4.1.4 Ultraviolet detector - Fixed wavelength (254 nm) with a semi-prep flow-through cell.

4.1.5 Strip chart recorder, recording integrator or laboratory data system.

4.1.6 Syringe - 10 mL with Luerlok fitting.

4.1.7 Syringe filter assembly, disposable - Bio-Rad "Prep Disc" sample filter assembly #343-0005, 25 mm, and 5 micron filter discs or equivalent. Check each batch for contaminants. Rinse each filter assembly (prior to use) with methylene chloride if necessary.

4.2 Analytical balance - 0.0001 g.

4.3 Volumetric flasks, Class A - 10 mL to 1000 mL

4.4 Graduated cylinders

5.0 REAGENTS

5.1 Methylene chloride, CH_2Cl_2 . Pesticide quality or equivalent.

5.1.1 Some brands of methylene chloride may contain unacceptably high levels of acid (HCl). Check the pH by shaking equal portions of methylene chloride and water, then check the pH of the water layer.

5.1.1.1 If the pH of the water layer is ≤ 5 , filter the entire supply of solvent through a 2 in. x 15 in. glass column containing activated basic alumina. This column should be sufficient for processing approximately 20-30 liters of solvent. Alternatively, find a different supply of methylene chloride.

5.2 Cyclohexane, C_6H_{12} . Pesticide quality or equivalent.

5.3 n-Butyl chloride, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{Cl}$. Pesticide quality or equivalent.

5.4 GPC Calibration Solution. Prepare a calibration solution in methylene chloride containing the following analytes (in elution order):

<u>Compound</u>	<u>mg/L</u>
corn oil	25,000
bis(2-ethylhexyl) phthalate	1,000
methoxychlor	200
perylene	20
sulfur	80

NOTE: Sulfur is not very soluble in methylene chloride, however, it is soluble in warm corn oil. Therefore, one approach is to weigh out the corn oil, warm it and transfer the weighed amount of sulfur into the warm corn oil. Mix it and then transfer into a volumetric flask with methylene chloride, along with the other calibration compounds.

Store the calibration solution in an amber glass bottle with a Teflon lined screw-cap at 4°C , and protect from light. (Refrigeration may cause the corn oil to precipitate. Before use, allow the calibration solution to stand at room temperature until the corn oil dissolves.) Replace the calibration standard solution every 6 months, or more frequently if necessary.

5.5 Corn Oil Spike for Gravimetric Screen. Prepare a solution of corn oil in methylene chloride (5 g/100 mL).

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 See the introductory material to this chapter, Organic Analytes, Sec. 4.1.

7.0 PROCEDURE

7.1 It is very important to have consistent laboratory temperatures during an entire GPC run, which could be 24 hours or more. If temperatures are not consistent, retention times will shift, and the dump and collect times determined by the calibration standard will no longer be appropriate. The ideal laboratory temperature to prevent outgassing of the methylene chloride is 72°F.

7.2 GPC Setup and Calibration

7.2.1 Column Preparation

7.2.1.1 Weigh out 70 g of Bio Beads (SX-3). Transfer them to a quart bottle with a Teflon lined cap or a 500 mL separatory funnel with a large bore stopcock, and add approximately 300 mL of methylene chloride. Swirl the container to ensure the wetting of all beads. Allow the beads to swell for a minimum of 2 hours. Maintain enough solvent to sufficiently cover the beads at all times. If a guard column is to be used, repeat the above with 5 g of Bio Beads in a 125 mL bottle or a beaker, using 25 mL of methylene chloride.

7.2.1.2 Turn the column upside down from its normal position, and remove the inlet bed support plunger (the inlet plunger is longer than the outlet plunger). Position and tighten the outlet bed support plunger as near the end as possible, but no closer than 5 cm (measured from the gel packing to the collar).

7.2.1.3 Raise the end of the outlet tube to keep the solvent in the GPC column, or close the column outlet stopcock if one is attached. Place a small amount of solvent in the column to minimize the formation of air bubbles at the base of poured column packing.

7.2.1.4 Swirl the bead/solvent slurry to get a homogeneous mixture and, if the wetting was done in a quart bottle, quickly transfer it to a 500 mL separatory funnel with a large bore stopcock. Drain the excess methylene chloride directly into the waste beaker, and then start draining the slurry into the column by placing the separatory funnel tip against the column wall. This will help to minimize bubble formation. Swirl occasionally to keep the slurry homogeneous. Drain enough to fill the column. Place the tubing from the column outlet into a waste beaker below the column, open the stopcock (if attached) and allow the excess solvent to drain. Raise the tube to stop the flow and close the stopcock when the top of the gel begins to look dry. Add additional methylene chloride to just rewet the gel.

7.2.1.5 Wipe any remaining beads and solvent from the inner walls of the top of the column with a laboratory tissue. Loosen the seal slightly on the other plunger assembly (long plunger) and insert it into the column. Make the seal just tight

enough so that any beads on the glass surface will be pushed forward, but loose enough so that the plunger can be pushed forward.

CAUTION: Do not tighten the seal if beads are between the seal and the glass surface because this can damage the seal and cause leakage.

7.2.1.6 Compress the column as much as possible without applying excessive force. Loosen the seal and gradually pull out the plunger. Rinse and wipe off the plunger. Slurry any remaining beads and transfer them into the column. Repeat Sec. 7.2.1.5 and reinsert the plunger. If the plunger cannot be inserted and pushed in without allowing beads to escape around the seal, continue compression of the beads without tightening the seal, and loosen and remove the plunger as described. Repeat this procedure until the plunger is successfully inserted.

7.2.1.7 Push the plunger until it meets the gel, then compress the column bed about four centimeters.

7.2.1.8 Pack the optional 5 cm column with approximately 5 g of preswelled beads (different guard columns may require different amounts). Connect the guard column to the inlet of the analytical column.

7.2.1.9 Connect the column inlet to the solvent reservoir (reservoir should be placed higher than the top of the column) and place the column outlet tube in a waste container. Placing a restrictor in the outlet tube will force air out of the column more quickly. A restrictor can be made from a piece of capillary stainless steel tubing of 1/16" OD x 10/1000" ID x 2". Pump methylene chloride through the column at a rate of 5 mL/min for one hour.

7.2.1.10 After washing the column for at least one hour, connect the column outlet tube, without the restrictor, to the inlet side of the UV detector. Connect the system outlet to the outlet side of the UV detector. A restrictor (same size as in Sec. 7.2.1.9) in the outlet tube from the UV detector will prevent bubble formation which causes a noisy UV baseline. The restrictor will not effect flow rate. After pumping methylene chloride through the column for an additional 1-2 hours, adjust the inlet bed support plunger until approximately 6-10 psi backpressure is achieved. Push the plunger in to increase pressure or slowly pull outward to reduce pressure.

7.2.1.11 When the GPC column is not to be used for several days, connect the column outlet line to the column inlet to prevent column drying and/or channeling. If channeling occurs, the gel must be removed from the column, reswelled, and repoured as described above. If drying occurs, methylene chloride should be pumped through the column until the observed column pressure is constant

and the column appears wet. Always recalibrate after column drying has occurred to verify retention volumes have not changed.

7.2.2 Calibration of the GPC Column

7.2.2.1 Using a 10 mL syringe, load sample loop #1 with calibration solution (Sec. 5.6). With the ABC automated system, the 5 mL sample loop requires a minimum of 8 mL of the calibration solution. Use a firm, continuous pressure to push the sample onto the loop. Switch the valve so that GPC flow is through the UV flow-through cell.

7.2.2.2 Inject the calibration solution and obtain a UV trace showing a discrete peak for each component. Adjust the detector and/or recorder sensitivity to produce a UV trace similar to Figure 2 that meets the following requirements. Differences between manufacturers' cell volumes and detector sensitivities may require a dilution of the calibration solution to achieve similar results. An analytical flow-through detector cell will require a much less concentrated solution than the semi-prep cell, and therefore the analytical cell is not acceptable for use.

7.2.2.3 Following are criteria for evaluating the UV chromatogram for column condition.

7.2.2.3.1 Peaks must be observed, and should be symmetrical, for all compounds in the calibration solution.

7.2.2.3.2 Corn oil and phthalate peaks must exhibit >85% resolution.

7.2.2.3.3 Phthalate and methoxychlor peaks must exhibit >85% resolution.

7.2.2.3.4 Methoxychlor and perylene peaks must exhibit >85% resolution.

7.2.2.3.5 Perylene and sulfur peaks must not be saturated and must exhibit >90% baseline resolution.

7.2.2.3.6 Nitroaromatic compounds are particularly prone to adsorption. For example, 4-nitrophenol recoveries may be low due to a portion of the analyte being discarded after the end of the collection time. Columns should be tested with the semivolatiles matrix spiking solution. GPC elution should continue until after perylene has eluted, or long enough to recover at least 85% of the analytes, whichever time is longer.

7.2.2.4 Calibration for Semivolatiles - Using the information from the UV trace, establish appropriate collect and dump time periods to ensure collection of all target analytes. Initiate column eluate collection just before elution of

bis(2-ethylhexyl) phthalate and after the elution of the corn oil. Stop eluate collection shortly after the elution of perylene. Collection should be stopped before sulfur elutes. Use a "wash" time of 10 minutes after the elution of sulfur. Each laboratory is required to establish its specific time sequences. See Figure 2 for general guidance on retention time. Figure 1 illustrates retention volumes for different classes of compounds.

7.2.2.5 Calibration for Organochlorine Pesticides/PCBs - Determine the elution times for the phthalate, methoxychlor, perylene, and sulfur. Choose a dump time which removes >85% of the phthalate, but collects >95% of the methoxychlor. Stop collection after the elution of perylene, but before sulfur elutes.

7.2.2.6 Verify the flow rate by collecting column eluate for 10 minutes in a graduated cylinder and measure the volume, which should be 45-55 mL (4.5-5.5 mL/min). If the flow rate is outside of this range, corrective action must be taken, as described above. Once the flow rate is within the range of 4.5-5.5 mL/min, record the column pressure (should be 6-10 psi) and room temperature. Changes in pressure, solvent flow rate, and temperature conditions can affect analyte retention times, and must be monitored. If the flow rate and/or column pressure do not fall within the above ranges, a new column should be prepared. A UV trace that does not meet the criteria in Sec. 7.2.2.3 would also indicate that a new column should be prepared. It may be necessary to obtain a new lot of Bio Beads if the column fails all the criteria.

7.2.2.7 Reinject the calibration solution after appropriate collect and dump cycles have been set, and the solvent flow and column pressure have been established.

7.2.2.7.1 Measure and record the volume of collected GPC eluate in a graduated cylinder. The volume of GPC eluate collected for each sample extract processed may be used to indicate problems with the system during sample processing.

7.2.2.7.2 The retention times for bis(2-ethylhexyl) phthalate and perylene must not vary more than $\pm 5\%$ between calibrations. If the retention time shift is >5%, take corrective action. Excessive retention time shifts are caused by:

7.2.2.7.2.1 Poor laboratory temperature control or system leaks.

7.2.2.7.2.2 An unstabilized column that requires pumping methylene chloride through it for several more hours or overnight.

7.2.2.7.2.3 Excessive laboratory temperatures, causing outgassing of the methylene chloride.

7.2.2.8 Analyze a GPC blank by loading 5 mL of methylene chloride into the GPC. Concentrate the methylene chloride that passes through the system during the collect cycle using a Kuderna-Danish (KD) evaporator. Analyze the concentrate by whatever detectors will be used for the analysis of future samples. Exchange the solvent, if necessary. If the blank exceeds the estimated quantitation limit of the analytes, pump additional methylene chloride through the system for 1-2 hours. Analyze another GPC blank to ensure the system is sufficiently clean. Repeat the methylene chloride pumping, if necessary.

7.3 Extract Preparation

7.3.1 Adjust the extract volume to 10.0 mL. The solvent extract must be primarily methylene chloride. All other solvents, e.g. 1:1 methylene chloride/acetone, must be concentrated to 1 mL (or as low as possible if a precipitate forms) and diluted to 10.0 mL with methylene chloride. Thoroughly mix the extract before proceeding.

7.3.2 Filter the extract through a 5 micron filter disc by attaching a syringe filter assembly containing the filter disc to a 10 mL syringe. Draw the sample extract through the filter assembly and into the 10 mL syringe. Disconnect the filter assembly before transferring the sample extract into a small glass container, e.g. a 15 mL culture tube with a Teflon lined screw cap. Alternatively, draw the extract into the syringe without the filter assembly. Attach the filter assembly and force the extract through the filter and into the glass container. The latter is the preferred technique for viscous extracts or extracts with a lot of solids. Particulate larger than 5 microns may scratch the valve, which may result in a system leak and cross-contamination of sample extracts in the sample loops. Repair of the damaged valve is quite expensive.

NOTE: Viscosity of a sample extract should not exceed the viscosity of 1:1 water/glycerol. Dilute samples that exceed this viscosity.

7.4 Screening the Extract

7.4.1 Screen the extract to determine the weight of dissolved residue by evaporating a 100 μ L aliquot to dryness and weighing the residue. The weight of dissolved residue loaded on the GPC column cannot exceed 0.500 g. Residues exceeding 0.500 g will very likely result in incomplete extract cleanup and contamination of the GPC switching valve (which results in cross-contamination of sample extracts).

7.4.1.1 Transfer 100 μ L of the filtered extract from Sec. 7.3.2 to a tared aluminum weighing dish.

7.4.1.2 A suggested evaporation technique is to use a heat lamp. Set up a 250 watt heat lamp in a hood so that it is 8 ± 0.5 cm from a surface covered with a clean sheet of aluminum foil. Surface temperature should be 80-100°C (check temperature by placing a thermometer on the foil and under the lamp). Place the

weighing dish under the lamp using tongs. Allow it to stay under the lamp for 1 min. Transfer the weighing dish to an analytical balance or a micro balance and weigh to the nearest 0.1 mg. If the residue weight is less than 10 mg/100 μ L, then further weighings are not necessary. If the residue weight is greater than 10 mg/100 μ L, then determine if constant weight has been achieved by placing the weighing dish and residue back under the heat lamp for 2 or more additional 0.5 min. intervals. Reweigh after each interval. Constant weight is achieved when three weights agree within $\pm 10\%$.

7.4.1.3 Repeat the above residue analysis on a blank and a spike. Add 100 μ L of the same methylene chloride used for the sample extraction to a weighing dish and determine residue as above. Add 100 μ L of a corn oil spike (5 g/100 mL) to another weighing dish and repeat the residue determination.

7.4.2 A residue weight of 10 mg/100 μ L of extract represents 500 mg in 5 mL of extract. Any sample extracts that exceed the 10 mg/100 μ L residue weight must be diluted so that the 5 mL loaded on the GPC column does not exceed 0.500 g. When making the dilution, keep in mind that a minimum volume of 8 mL is required when loading the ABC GPC unit. Following is a calculation that may be used to determine what dilution is necessary if the residue exceeds 10 mg.

$$\begin{array}{rclcl} Y \text{ mL taken} & = & 10 \text{ mL final} & \times & \frac{10 \text{ mg maximum}}{X \text{ mg of residue}} \\ \text{for dilution} & & \text{volume} & & \end{array}$$

Example:

$$\begin{array}{rclcl} Y \text{ mL taken} & = & 10 \text{ mL final} & \times & \frac{10 \text{ mg maximum}}{15 \text{ mg of residue}} \\ \text{for dilution} & & \text{volume} & & \end{array}$$

$$Y \text{ mL taken for dilution} = 6.7 \text{ mL}$$

Therefore, taking 6.7 mL of sample extract from Sec. 7.3.2, and diluting to 10 mL with methylene chloride, will result in 5 mL of diluted extract loaded on the GPC column that contains 0.500 g of residue.

NOTE: This dilution factor must be included in the final calculation of analyte concentrations. In the above example, the dilution factor is 1.5.

7.5 GPC Cleanup

7.5.1 Calibrate the GPC at least once per week following the procedure outlined in Secs. 7.2.2 through 7.2.2.6. Ensure that UV trace requirements, flow rate and column pressure criteria are acceptable. Also, the retention time shift must be $<5\%$ when compared to retention times in the last calibration UV trace.

7.5.1.1 If these criteria are not met, try cleaning the column by loading one or more 5 mL portions of butyl chloride and running it through the column. Butyl chloride or 9:1 (v/v)

methylene chloride/methanol removes the discoloration and particulate that may have precipitated out of the methylene chloride extracts. Backflushing (reverse flow) with methylene chloride to dislodge particulates may restore lost resolution. If a guard column is being used, replace it with a new one. This may correct the problem. If column maintenance does not restore acceptable performance, the column must be repacked with new Bio Beads and calibrated.

7.5.2 Draw a minimum of 8 mL of extract (diluted, if necessary, and filtered) into a 10 mL syringe.

7.5.3 Attach the syringe to the turn lock on the injection port. Use firm, continuous pressure to push the sample onto the 5-mL sample loop. If the sample is difficult to load, some part of the system may be blocked. Take appropriate corrective action. If the back pressure is normal (6-10 psi), the blockage is probably in the valve. Blockage may be flushed out of the valve by reversing the inlet and outlet tubes and pumping solvent through the tubes. (This should be done before sample loading.)

NOTE: Approximately 2 mL of the extract remains in the lines between the injection port and the sample loop; excess sample also passes through the sample loop to waste.

7.5.4 After loading a loop, and before removing the syringe from the injection port, index the GPC to the next loop. This will prevent loss of sample caused by unequal pressure in the loops.

7.5.5 After loading each sample loop, wash the loading port with methylene chloride in a PTFE wash bottle to minimize cross-contamination. Inject approximately 10 mL of methylene chloride to rinse the common tubes.

7.5.6 After loading all the sample loops, index the GPC to the 00 position, switch to the "RUN" mode and start the automated sequence. Process each sample using the collect and dump cycle times established in Sec. 7.2.2.

7.5.7 Collect each sample in a 250 mL Erlenmeyer flask, covered with aluminum foil to reduce solvent evaporation, or directly into a Kuderna-Danish evaporator. Monitor sample volumes collected. Changes in sample volumes collected may indicate one or more of the following problems:

7.5.7.1 Change in solvent flow rate, caused by channeling in the column or changes in column pressure.

7.5.7.2 Increase in column operating pressure due to the absorption of particles or gel fines onto either the guard column or the analytical column gel, if a guard column is not used.

7.5.7.3 Leaks in the system or significant variances in room temperature.

7.6 Concentrate the extract by the standard K-D technique (see any of the extraction methods, Sec. 4.2.1 of this chapter). See the determinative methods (Chapter Four, Sec. 4.3) for the final volume.

7.7 It should be remembered that only half of the sample extract is processed by the GPC (5 mL of the 10 mL extract is loaded onto the GPC column), and thus, a dilution factor of 2 (or 2 multiplied by any dilution factor in Sec. 7.4.2) must be used for quantitation of the sample in the determinative method.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One and Method 3600 for specific quality control procedures.

8.2 The analyst should demonstrate that the compound(s) of interest are being quantitatively recovered before applying this method to actual samples.

8.3 For sample extracts that are cleaned up using this method, the associated quality control samples must also be processed through this cleanup method.

9.0 METHOD PERFORMANCE

9.1 Refer to Table 1 for single laboratory performance data.

ALUMINA COLUMN CLEANUP AND SEPARATION OF PETROLEUM WASTES

1.0 SCOPE AND APPLICATION

1.1 Alumina is a highly porous and granular form of aluminum oxide. It is available in three pH ranges (basic, neutral, and acidic) for use in chromatographic cleanup procedures. Method 3611 utilizes neutral pH alumina to separate petroleum wastes into aliphatic, aromatic, and polar fractions.

1.2 Method 3611 was formerly Method 3570 in the Second Edition of this manual.

1.3 This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 The column is packed with the required amount of adsorbent, topped with a water adsorbent, and then loaded with the sample to be analyzed. Elution of the analytes is effected with a suitable solvent(s), leaving the interfering compounds on the column. The eluate is then concentrated (if necessary).

3.0 INTERFERENCES

3.1 A reagent blank should be performed for the compounds of interest prior to the use of this method. The level of interferences must be below the method detection limit before this method is performed on actual samples.

3.2 More extensive procedures than those outlined in this method may be necessary for reagent purification.

3.3 Caution must be taken to prevent overloading of the chromatographic column. As the column loading for any of these types of wastes approaches 0.300 g of extractable organics, separation recoveries will suffer. If overloading is suspected, an aliquot of the base-neutral extract prior to cleanup may be weighed and then evaporated to dryness. A gravimetric determination on the aliquot will indicate the weight of extractable organics in the sample.

3.4 Mixtures of petroleum wastes containing predominantly polar solvents, i.e., chlorinated solvents or oxygenated solvents, are not appropriate for this method.

4.0 APPARATUS AND MATERIALS

4.1 Chromatography column: 300 mm x 10 mm ID, with Pyrex® glass wool at bottom and a polytetrafluoroethylene (PTFE) stopcock.

NOTE: Fritted glass discs are difficult to decontaminate after highly contaminated extracts have been passed through. Columns without frits may be purchased. Use a small pad of Pyrex® glass wool to retain the adsorbent. Prewash the

glass wool pad with 50 mL of acetone followed by 50 mL of elution solvent prior to packing the column with adsorbent.

4.2 Beakers: Appropriate sizes.

4.3 Reagent bottle: Appropriate sizes.

4.4 Muffle furnace.

4.5 Water bath: Heated with concentric ring cover, capable of temperature control ($\pm 5^{\circ}\text{C}$). The bath should be used in a hood.

4.6 Erlenmeyer flasks: 50 and 250 mL.

5.0 REAGENTS

5.1 Sodium sulfate: (granular, anhydrous), Na_2SO_4 . Purify by heating at 400°C for 4 hours in a shallow tray, or by precleaning the sodium sulfate with methylene chloride. If the sodium sulfate is precleaned with methylene chloride, a method blank must be analyzed, demonstrating that there is no interference from the sodium sulfate.

5.2 Eluting solvents:

5.2.1 Methanol, CH_3OH - Pesticide quality or equivalent.

5.2.2 Hexane, C_6H_{14} - Pesticide quality or equivalent.

5.2.3 Methylene chloride, CH_2Cl_2 - Pesticide quality or equivalent.

5.3 Alumina: Neutral 80-325 MCB chromatographic grade or equivalent. Dry alumina overnight at 130°C prior to use.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

See the introductory material to this chapter, Organic Analytes, Sec. 4.1.

7.0 PROCEDURE

7.1 It is suggested that Method 3650, Acid-Base Partition Cleanup, be performed on the sample extract prior to alumina cleanup.

7.2 Place approximately 10 g of alumina into a chromatographic column, tap to settle the alumina, and add 1 cm of anhydrous sodium sulfate to the top.

7.3 Pre-elute the column with 50 mL of hexane. Discard the eluate and, just prior to exposure of the sodium sulfate layer to the air, quantitatively transfer the 1 mL sample extract onto the column using an additional 1 mL of hexane to complete the transfer. To avoid overloading the column, it is suggested that no more than 0.300 g of extractable organics be placed on the column (see Sec. 3.3).

7.4 Just prior to exposure of the sodium sulfate to the air, elute the column with a total of 15 mL of hexane. If the extract is in 1 mL of hexane, and if 1 mL of hexane was used as a rinse, then 13 mL of additional hexane should be used. Collect the effluent in a 50 mL flask and label this fraction "base/neutral aliphatics." Adjust the flow rate to 2 mL/min.

7.5 Elute the column with 100 mL of methylene chloride and collect the effluent in a 250 mL flask. Label this fraction "base/neutral aromatics."

7.6 Elute the column with 100 mL of methanol and collect the effluent in a 250 mL flask. Label this fraction "base/neutral polars."

7.7 Following cleanup, concentrate the fractions to the final volumes listed in the appropriate determinative method, using the techniques described in an appropriate 3500 series method. Analysis follows as specified in the determinative procedure.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One for specific quality control procedures and Method 3600 for cleanup procedures.

8.2 The analyst should demonstrate that the compounds of interest are being quantitatively recovered before applying this method to actual samples.

8.3 For sample extracts that are cleaned up using this method, the associated quality control samples must also be processed through this cleanup method.

9.0 METHOD PERFORMANCE

9.1 The precision and accuracy of the method will depend upon the overall performance of the sample preparation and analysis.

9.2 Rag oil is an emulsion consisting of crude oil, water, and soil particles. It has a density greater than crude oil and less than water. This material forms a layer between the crude oil and water when the crude oil is allowed to gravity separate at the refinery. A rag oil sample was analyzed by a number of laboratories according to the procedure outlined in this method. The results of these analyses by GC/MS for selected components in the rag oil are presented in Table 1. Reconstructed ion chromatograms from the GC/MS analyses are included as Figures 1 and 2.

METHOD 3630C

SILICA GEL CLEANUP

1.0 SCOPE AND APPLICATION

1.1 Silica gel (silicic acid) is a regenerative adsorbent of silica with weakly acidic properties. It is produced from sodium silicate and sulfuric acid. Silica gel can be used in column chromatography for the separation of analytes from interfering compounds of a different chemical polarity. It may be used activated, after heating to 150 - 160°C, or deactivated with up to 10% water.

1.2 This method includes guidance for standard column cleanup of sample extracts containing polynuclear aromatic hydrocarbons, derivatized phenolic compounds, organochlorine pesticides, and PCBs as Aroclors.

1.3 This method also provides cleanup procedures using solid-phase extraction cartridges for pentafluorobenzyl bromide-derivatized phenols, organochlorine pesticides, and PCBs. This technique also provides the best separation of PCBs from most single component organochlorine pesticides. When only PCBs are to be measured, this method can be used in conjunction with sulfuric acid/permanganate cleanup (Method 3665).

1.4 Other analytes may be cleaned up using this method if the analyte recovery meets the criteria specified in Sec. 8.0.

1.5 This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 This method provides the option of using either standard column chromatography techniques or solid-phase extraction cartridges. Generally, the standard column chromatography techniques use larger amounts of adsorbent and, therefore, have a greater cleanup capacity.

2.2 In the standard column cleanup protocol, the column is packed with the required amount of adsorbent, topped with a water adsorbent, and then loaded with the sample to be analyzed. Elution of the analytes is accomplished with a suitable solvent(s) that leaves the interfering compounds on the column. The eluate is then concentrated (if necessary).

2.3 The cartridge cleanup protocol uses solid-phase extraction cartridges packed with 1 g or 2 g of silica gel (silicic acid) adsorbent. Each cartridge is solvent washed immediately prior to use. Aliquots of sample extracts are loaded onto the cartridges, which are then eluted with suitable solvent(s). A vacuum manifold is required to obtain reproducible results. The collected fractions may be further concentrated prior to gas chromatographic analysis.

2.4 The appropriate gas chromatographic method is listed at the end of each technique. Analysis may also be performed by gas chromatography/mass spectrometry (Method 8270).

3.0 INTERFERENCES

3.1 Solvents, reagents, glassware, and other sample processing hardware may yield discrete artifacts and/or elevated baselines causing misinterpretation of gas chromatograms. All these materials must be demonstrated to be free from interferences under the conditions of the analysis, by analyzing reagent blanks. See Sec. 8 for guidance on a reagent blank check.

3.2 Phthalate ester contamination may be a problem with certain cartridges. The more inert the column and/or cartridge material (i.e., glass or polytetrafluoroethylene (PTFE)), the less problem with phthalates. Phthalates create interference problems for all method analytes, not just the phthalate esters themselves.

3.3 More extensive procedures than those outlined in this method may be necessary for reagent purification.

4.0 APPARATUS AND MATERIALS

4.1 Chromatographic column - 250 mm long x 10 mm ID; with Pyrex® glass wool at bottom and a PTFE stopcock.

NOTE: Fritted glass discs are difficult to decontaminate after highly contaminated extracts have been passed through. Columns without frits may be purchased. Use a small pad of Pyrex® glass wool to retain the adsorbent. Prewash the glass wool pad with 50 mL of acetone followed by 50 mL of elution solvent prior to packing the column with adsorbent.

4.2 Beakers - appropriate sizes.

4.3 Vials - 2, 10, 25 mL, glass with PTFE-lined screw-caps or crimp tops.

4.4 Muffle furnace.

4.5 Reagent bottle - appropriate sizes.

4.6 Erlenmeyer flasks - 50 and 250 mL.

4.7 Vacuum manifold: VacElute Manifold SPS-24 (Analytichem International), Visiprep (Supelco, Inc.) or equivalent, consisting of glass vacuum basin, collection rack and funnel, collection vials, replaceable stainless steel delivery tips, built-in vacuum bleed valve and gauge. The system is connected to a vacuum pump or water aspirator through a vacuum trap made from a 500 mL sidearm flask fitted with a one-hole stopper and glass tubing.

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Organic-free reagent water. All references to water in this method refer to organic-free reagent water, as defined in Chapter One.

5.3 Silica gel for chromatography columns.

5.3.1 Silica Gel for Phenols and Polynuclear Aromatic Hydrocarbons: 100/200 mesh (Davison Chemical grade 923 or equivalent). Before use, activate for at least 16 hr. at 130°C in a shallow glass tray, loosely covered with foil.

5.3.2 Silica Gel for Organochlorine pesticides/PCBs: 100/200 mesh (Davison Chemical grade 923 or equivalent). Before use, activate for at least 16 hr. at 130°C in a shallow glass tray, loosely covered with foil. Deactivate it to 3.3% with reagent water in a 500 mL glass jar. Mix the contents thoroughly and allow to equilibrate for 6 hours. Store the deactivated silica gel in a sealed glass jar inside a desiccator.

5.4 Silica cartridges: 40 µm particles, 60 A pores. The cartridges with which this method was developed consist of 6 mL serological-grade polypropylene tubes, with the 1 g of silica held between two polyethylene or stainless steel frits with 20 µm pores. 2 g silica cartridges are also used in this method, and 0.5 g cartridges are available. The compound elution patterns must be verified when cartridges other than the specified size are used.

5.5 Sodium sulfate (granular, anhydrous), Na₂SO₄. Purify by heating at 400°C for 4 hours in a shallow tray, or by precleaning the sodium sulfate with methylene chloride. A method blank must be analyzed in order to demonstrate that there is no interference from the sodium sulfate.

5.6 Eluting solvents

5.6.1 Cyclohexane, C₆H₁₂ - Pesticide quality or equivalent.

5.6.2 Hexane, C₆H₁₄ - Pesticide quality or equivalent.

5.6.3 2-Propanol, (CH₃)₂CHOH - Pesticide quality or equivalent.

5.6.4 Toluene, C₆H₅CH₃ - Pesticide quality or equivalent.

5.6.5 Methylene chloride, CH₂Cl₂ - Pesticide quality or equivalent.

5.6.6 Pentane, C₅H₁₂ - Pesticide quality or equivalent.

5.6.7 Acetone, CH₃COCH₃ - Pesticide quality or equivalent.

5.6.8 Diethyl Ether, C₂H₅OC₂H₅. Pesticide quality or equivalent. Must be free of peroxides as indicated by test strips (EM Quant, or equivalent). Procedures for removal of peroxides are provided with the test strips. After cleanup, 20 mL of ethanol preservative must be added to each liter of ether.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 See the introductory material to this chapter, Organic Analytes, Sec. 4.1.

7.0 PROCEDURE

7.1 General Guidance

7.1.1 The procedure contains two cleanup options for the derivatized phenols and organochlorine pesticides/PCBs, but only one technique for the polynuclear aromatic hydrocarbons (PAHs) (standard column chromatography). Cleanup techniques by standard column chromatography for all analytes are found in Sec. 7.2. Cleanup techniques by solid-phase cartridges for derivatized phenols and PAHs are found in Sec. 7.3. The standard column chromatography techniques are packed with a greater amount of silica gel adsorbent and, therefore, have a greater cleanup capacity. A rule of thumb relating to cleanup capacity is that 1 g of sorbent material will remove 10 to 30 mg of total interferences. (However, capacity is also dependent on the sorbent retentiveness of the interferences.) Therefore, samples that exhibit a greater degree of sample interference should be cleaned up by the standard column technique. However, both techniques have limits on the amount of interference that can be removed. If the interference is caused by high boiling material, then Method 3640 should be used prior to this method. If the interference is caused by relatively polar compounds of the same boiling range as the analytes, then multiple column or cartridge cleanups may be required. If crystals of sulfur are noted in the extract, then Method 3660 should be utilized prior to this method. The cartridge cleanup techniques are often faster and use less solvent, however they have less cleanup capacity.

7.1.2 Allow the extract to reach room temperature if it was in cold storage. Inspect the extracts visually to ensure that there are no particulates or phase separations and that the volume is as stated in the accompanying documents. Verify that the solvent is compatible with the cleanup procedures. If crystals of sulfur are visible or if the presence of sulfur is suspected, proceed with Method 3660.

7.1.3 If the extract solvent is methylene chloride, for most cleanup techniques, it must be exchanged to hexane. (For the PAHs, exchange to cyclohexane as per Sec. 7.2.1). Follow one of the standard concentration techniques provided in each extraction method. The volume of methylene chloride should have been reduced to 1-2 mL. Add 40 mL of hexane, a fresh boiling chip and repeat the concentration as written. The final volume required for the cleanup techniques is normally 2 mL.

7.2 Standard Column Cleanup Techniques

7.2.1 Polynuclear aromatic hydrocarbons

7.2.1.1 Before the silica gel cleanup technique can be utilized, the extract solvent must be exchanged to cyclohexane. The exchange is performed by adding 4 mL of cyclohexane following reduction of the sample extract to 1-2 mL using an appropriate concentration technique (e.g., K-D using two-ball micro-snyder column) found in the 3500 series methods. The final extract volume is 2.0 mL.

CAUTION: When the volume of solvent is reduced below 1 mL, semivolatile analytes may be lost. If the extract goes to dryness, the extraction must be repeated.

7.2.1.2 Prepare a slurry of 10 g of activated silica gel (Sec. 5.3.1) in methylene chloride and place this into a 10 mm ID chromatographic column. Tap the column to

settle the silica gel and elute the methylene chloride. Add 1 to 2 cm of anhydrous sodium sulfate to the top of the silica gel.

7.2.1.3 Pre-elute the column with 40 mL of pentane. The rate for all elutions should be about 2 mL/min. Discard the eluate and, just prior to exposure of the sodium sulfate layer to the air, transfer the 2 mL cyclohexane sample extract onto the column using an additional 2 mL cyclohexane to complete the transfer. Just prior to exposure of the sodium sulfate layer to the air, add 25 mL of pentane and continue the elution of the column. Discard this pentane eluate.

7.2.1.4 Next, elute the column with 25 mL of methylene chloride/pentane (2:3)(v/v) into a flask for concentration. Concentrate the collected fraction to whatever volume is required (1-10 mL). Proceed with HPLC (Method 8310) or GC analysis (Method 8100). Validated components that elute in this fraction are:

Acenaphthene	Chrysene
Acenaphthylene	Dibenzo(a,h)anthracene
Anthracene	Fluoranthene
Benzo(a)anthracene	Fluorene
Benzo(a)pyrene	Indeno(1,2,3-cd)pyrene
Benzo(b)fluoranthene	Naphthalene
Benzo(g,h,i)perylene	Phenanthrene
Benzo(k)fluoranthene	Pyrene

7.2.2 Derivatized Phenols

7.2.2.1 This silica gel cleanup procedure is performed on sample extracts that have undergone pentafluorobenzyl bromide derivatization, as described in Method 8041. The sample extract must be in 2 mL of hexane at this point.

7.2.2.2 Place 4.0 g of activated silica gel (Sec. 5.3.1) into a 10 mm ID chromatographic column. Tap the column to settle the silica gel and add about 2 g of anhydrous sodium sulfate to the top of the silica gel.

7.2.2.3 Pre-elute the column with 6 mL of hexane. The rate for all elutions should be about 2 mL/min. Discard the eluate and, just prior to exposure of the sodium sulfate layer to the air, pipet onto the column 2 mL of the hexane solution that contains the derivatized sample or standard. Elute the column with 10.0 mL of hexane and discard the eluate.

7.2.2.4 Elute the column, in order, with 10.0 mL of 15% toluene in hexane (Fraction 1); 10.0 mL of 40% toluene in hexane (Fraction 2); 10.0 mL of 75% toluene in hexane (Fraction 3); and 10.0 mL of 15% 2-propanol in toluene (Fraction 4). All elution mixtures are prepared on a volume:volume basis. Elution patterns for the phenolic derivatives are shown in Table 1. Fractions may be combined, as desired, depending upon the specific phenols of interest or level of interferences. Proceed with GC analysis.

7.2.3 Organochlorine Pesticides and PCBs

7.2.3.1 Transfer a 3 g portion of deactivated silica gel (Sec. 5.3.2) into a 10 mm ID glass chromatographic column and top it with 2 to 3 cm of anhydrous sodium sulfate.

7.2.3.2 Add 10 mL of hexane to the top of the column to wet and rinse the sodium sulfate and silica gel. Just prior to exposure of the sodium sulfate layer to air, stop the hexane eluate flow by closing the stopcock on the chromatographic column. Discard the eluate.

7.2.3.3 Transfer the sample extract (2 mL in hexane) onto the column. Rinse the extract vial twice with 1 to 2 mL of hexane and add each rinse to the column. Elute the column with 80 mL of hexane (Fraction I) at a rate of about 5 mL/min. Remove the collection flask and set it aside for later concentration. Elute the column with 50 mL of hexane (Fraction II) and collect the eluate. Perform a third elution with 15 mL of methylene chloride (Fraction III). The elution patterns for the organochlorine pesticides, Aroclor-1016, and Aroclor-1260 are shown in Table 2.

7.2.3.4 Prior to gas chromatographic analysis, the extraction solvent must be exchanged to hexane. Fractions may be combined, as desired, depending upon the specific pesticides/PCBs of interest or level of interferences. Analyze Fraction I containing PCBs separated from most pesticides by Method 8082. Use Method 8081 to analyze for organochlorine pesticides.

7.3 Cartridge Cleanup Techniques

7.3.1 Cartridge Set-up and Conditioning

7.3.1.1 Arrange the 1 g silica cartridges (2 g for phenol cleanup) on the manifold in the closed-valve position. Other size cartridges may be used, however the data presented in the Tables are all based on 1 g cartridges for pesticides/PCBs and 2 g cartridges for phenols. Therefore, supporting recovery data must be developed for other sizes. Larger cartridges will probably require larger volumes of elution solvents.

7.3.1.2 Turn on the vacuum pump and set pump vacuum to 10 inches (254 mm) of Hg. Do not exceed the manufacturer's recommendation for manifold vacuum. Flow rates can be controlled by opening and closing cartridge valves.

7.3.1.3 Condition the cartridges by adding 4 mL of hexane to each cartridge. Slowly open the cartridge valves to allow hexane to pass through the sorbent beds to the lower frits. Allow a few drops per cartridge to pass through the manifold to remove all air bubbles. Close the valves and allow the solvent to soak the entire sorbent bed for 5 minutes. Do not turn off the vacuum.

7.3.1.4 Slowly open cartridge valves to allow the hexane to pass through the cartridges. Close the cartridge valves when there is still at least 1 mm of solvent above the sorbent bed. Do not allow cartridges to become dry. If cartridges go dry, repeat the conditioning step.

7.3.2 Derivatized Phenols

7.3.2.1 Reduce the sample extract volume to 2 mL prior to cleanup. The extract solvent must be hexane and the phenols must have undergone derivatization by pentafluorobenzyl bromide, as per the appropriate method.

7.3.2.2 Transfer the extract to the 2 g cartridge that has been conditioned as described in Sec. 7.3.1. Open the cartridge valve to allow the extract to pass through the cartridge bed at approximately 2 mL/minute.

7.3.2.3 When the entire extract has passed through the cartridges, but before the cartridge becomes dry, rinse the sample vials with an additional 0.5 mL of hexane, and add the rinse to the cartridges to complete the quantitative transfer.

7.3.2.4 Close the cartridge valve and turn off the vacuum after the solvent has passed through, ensuring that the cartridge never gets dry.

7.3.2.5 Place a 5 mL vial or volumetric flask into the sample rack corresponding to the cartridge position. Attach a solvent-rinsed stainless steel solvent guide to the manifold cover and align with the collection vial.

7.3.2.6 Add 5 mL of hexane to the cartridge. Turn on the vacuum pump and adjust the pump pressure to 10 inches (254 mm) of Hg. Allow the solvent to soak the sorbent bed for 1 minute or less. Slowly open the cartridge valve, and collect the eluate (this is Fraction 1, and should be discarded).

NOTE: If cartridges smaller than 2 g are used, then Fraction 1 cannot be discarded, since it contains some of the phenols.

7.3.2.7 Close the cartridge valve, replace the collection vial, and add 5 mL of toluene/hexane (25/75, v/v) to the cartridge. Slowly open the cartridge valve and collect the eluate into the collection vial. This is Fraction 2, and should be retained for analysis.

7.3.2.8 Adjust the final volume of the eluant to a known volume which will result in analyte concentrations appropriate for the project requirements (normally 1 - 10 mL) using techniques described in an appropriate 3500 series method. Table 3 shows compound recoveries for 2 g silica cartridges. The cleaned up extracts are ready for analysis by Method 8041.

7.3.3 Organochlorine Pesticides/PCBs

NOTE: The silica cartridge procedure is appropriate when polychlorinated biphenyls are known to be present.

7.3.3.1 Reduce the sample extract volume to 2 mL prior to cleanup. The extract solvent must be hexane.

7.3.3.2 Use the 1 g cartridges conditioned as described in Sec. 7.3.1.

7.3.3.3 Transfer the extract to the cartridge. Open the cartridge valve to allow the extract to pass through the cartridge bed at approximately 2 mL/minute.

7.3.3.4 When the entire extract has passed through the cartridges, but before the cartridge becomes dry, rinse the sample vials with an additional 0.5 mL of solvent, and add the rinse to the cartridges to complete the quantitative transfer.

7.3.3.5 Close the cartridge valve and turn off the vacuum after the solvent has passed through, ensuring that the cartridge never goes dry.

7.3.3.6 Place a 5 mL vial or volumetric flask into the sample rack corresponding to the cartridge position. Attach a solvent-rinsed stainless steel solvent guide to the manifold cover and align with the collection vial.

7.3.3.7 Add 5 mL of hexane to the cartridge. Turn on the vacuum pump and adjust the pump pressure to 10 inches (254 mm) of Hg. Allow the solvent to soak the sorbent bed for 1 minute or less. Slowly open the cartridge valve and collect the eluate into the collection vial (Fraction 1).

7.3.3.8 Close the cartridge valve, replace the collection vial, and add 5 mL of diethyl ether/hexane (50/50, v/v) to the cartridge. Slowly open the cartridge valve and collect the eluate into the collection vial (Fraction 2).

7.3.3.9 Adjust the final volume of each of the two fractions to a known volume which will result in analyte concentrations appropriate for the project requirements (normally 1 - 10 mL) using techniques described in an appropriate 3500 series method. The fractions may be combined prior to final adjustment of volume, if analyte fractionation is not required. Table 4 shows compound recoveries for 1 g silica cartridges. The cleaned up extracts are ready for analysis by Methods 8081 for organochlorine pesticides or 8082 for PCBs.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One for specific quality control procedures and Method 3600 for cleanup procedures.

8.2 A reagent blank (consisting of the elution solvents) must be passed through the column or cartridge and checked for the compounds of interest, prior to the use of this method. This same performance check is required with each new lot of adsorbent or cartridges. The level of interferences must be below the method detection limit before this method is performed on actual samples.

8.3 The analyst must demonstrate that the compounds of interest are being quantitatively recovered before applying this method to actual samples. See the attached Tables for acceptable recovery data. For compounds that have not been tested, recovery must be $\geq 85\%$.

8.3.1 Before any samples are processed using the solid-phase extraction cartridges, the efficiency of the cartridge must be verified. A recovery check must be performed using standards of the target analytes at known concentration. Only lots of cartridges that meet the recovery criteria for the spiked compounds can be used to process the samples.

8.3.2 A check should also be performed on each individual lot of cartridges and for every 300 cartridges of a particular lot.

8.4 For sample extracts that are cleaned up using this method, the associated quality control samples should also be processed through this cleanup method.

9.0 METHOD PERFORMANCE

9.1 Table 1 provides performance information on the fractionation of phenolic derivatives using standard column chromatography.

9.2 Table 2 provides performance information on the fractionation of organochlorine pesticides and Aroclors using standard column chromatography.

9.3 Table 3 shows recoveries of derivatized phenols obtained using 2 g silica cartridges.

9.4 Table 4 shows recoveries and fractionation of organochlorine pesticides obtained using 1 g silica cartridges.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132

Scope:

This method is based on a purge and trap, gas chromatography (GC) procedure and is used to determine the concentration of gasoline range organics (GRO) in soil. Generally, this corresponds to an alkane range of approximately C6 through C12. The carbon range can be modified to comply with differing regulatory needs.

The following is a list of the various analysis numbers used to report GRO using SW846 8015B method with the exception of analysis 10599 which uses SW846 8015C. OA-1 uses the 1637, 1638 analyses and is run identically to 8015B:

Analysis Number	Description	Range	Retention Time Marker – Start of Range	Retention Time Marker – End of Range	Reporting Limit mg/kg
1637	GRO	C6 – C10	2-methylpentane	1,2,4-trimethylbenzene	1
1638	GRO, used with BTEX scan	C6 – C10	2-methylpentane	1,2,4-trimethylbenzene	1
1700	GRO – Northern CA (special reporting limit)	C6 – C12	n-hexane	Naphthalene	100 µg/kg (MDL) 1000 µg/kg (LOQ)
1725	GRO – Northern CA	C6 - C12	n-hexane	Naphthalene	1
1726	GRO – Northern CA, with BTEX	C6 - C12	n-hexane	Naphthalene	1
2765	GRO – Louisiana	C6 – C10	n-hexane	n-decane	1
2766	GRO – Louisiana, with BTEX	C6 – C10	n-hexane	n-decane	1
5550	GRO – Southern CA, with BTEX	C5 – C12	First discernable peak after the methanol/solvent front (calibration standard)	Last discernable peak in the chromatogram (Naphthalene)	1
5551	GRO – Southern CA	C5 – C12	First discernable peak after the methanol/solvent front (calibration standard)	Last discernable peak in the chromatogram (Naphthalene)	1
10599	GRO	C6 – C10	2-methylpentane	1,2,4-trimethylbenzene	1
12989	Fractionated GRO	C5 – C12	First discernable peak after the methanol/solvent front (calibration standard)	Last discernable peak in the chromatogram (Naphthalene)	1
		C5 – C6	First discernable peak after the methanol/solvent front (calibration standard)	n-hexane	1
		>C6 – C8	n-hexane	n-octane	1
		>C8 – C10	n-octane	n-decane	1
		>C10 – C12	n-decane	Naphthalene	1

This method can be run in series with a photoionization detector (PID) to analyze for BTEX and oxygenates using SW846 Method 8020 or 8021.

Revision: 15	Effective date: Sep 16, 2013	Page 4 of 23
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

Basic Principles:

Soil samples are dispersed in methanol, refer to Analysis #1150, 6170, 6130, and 6117 for specifics, to dissolve volatile organic constituents. A portion of this methanol extract is diluted into reagent water and analyzed by purge and trap gas chromatography. Detection is achieved by a flame ionization detector (FID). Quantitation is performed by comparing the area of all chromatographic peaks (including resolved and unresolved components) eluting between the retention times for the start and stop of the hydrocarbon range in the sample to the total area over that same range in a gasoline standard.

Interferences:

High levels of solvents or petroleum products may contain volatile compounds that may elute within the retention time of the GRO.

Samples can become contaminated by diffusion of volatiles through the sample vial septum. A trip blank carried through sampling, storage and handling can act as a check of such contamination.

Contamination by carryover can occur whenever high-level and low-level samples are analyzed sequentially. To reduce carryover, the sample syringe and/or purge vessel must be rinsed between samples with reagent water. Whenever a highly concentrated sample is analyzed, it must be followed by a instrument blank to check for cross-contamination.

The trap and other parts of the system are subject to contamination. Frequent bake-out and purging of the system may be required.

Each chromatogram is reviewed for interference. If an interfering peak is observed either just prior to or immediately after the surrogate peak or the contamination level in the sample causes the integrator to improperly set the baseline, manual integration may be needed.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132

Safety Precautions and Waste Handling:

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

The toxicity of all compounds used in this method has not been established. However, several of the compounds are considered carcinogens. Each compound must be treated as a potential health hazard. The major route of exposure is inhalation during the handling of any stock standards while preparing secondary dilution standards. Therefore, these stocks must be prepared in a fume hood to eliminate the risk of inhaling the vapors. Information concerning the known toxicity, properties, or any special handling precautions can be found in the material safety data sheets (MSDS) available from the Safety Officer. Safety glasses and lab coats are required as personal protective wear.

The solvents utilized in this procedure are disposed of in a solvent waste container. Expired standards in methanol are disposed of as hazardous waste. All working solutions prepared in reagent water are flushed down the sink with tap water. Methanolic extracts of samples are returned to the sample storage area for future disposal. Soil sample extracts are collected and disposed of as solvent waste.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and an annual documented Demonstration of Capability (DOC).

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

Initially, each analyst performing instrumental analysis must work with an experienced analyst for a period of time until they can independently calibrate the instrument, use the chromatography data system to set up sequences, perform the calculations, interpret chromatograms, perform instrument maintenance, and enter data into the LIMS. Proficiency is measured through documented audits of the tasks listed and over checking of data as well as an Initial Demonstration of Capability (IDOC). Refer to 1-P-QM-QMA-9015390 for specific requirements. Demonstration of Capability is performed annually and is maintained in the analyst's training records.

Sample Collection, Preservation, and Handling:

Samples are to be collected using the recommended sampling protocol in EPA SW-846, Method 5030A and 5035B. Samples are refrigerated at 0° to 6°C, not frozen, and must be analyzed within 14 days of collection.

Samples are prepped using a 1:1 ratio of soil to methanol in accordance to Analysis #1150, 6170, or Analysis #8389, 8390, 6130, 6117, 6174, 7578, 7320.

Apparatus and Equipment:

1. Gas chromatograph – Hewlett Packard 5890 or equivalent suitable for purge and trap sample introduction
2. Detector – FID (in series with a PID if BTEX constituents are to be analyzed along with GRO)
3. GC column – DB VRX GC column, 75m × 0.45 mm × 2.55 um, or equivalent, (capable of resolving early-eluting constituents from the solvent front and ethylbenzene from *m/p*-xylene when BTEX is performed in series)
4. Purge and trap concentrator (P&T) – O.I. Analytical Model 4560 or equivalent with the following specifications. The purging chamber (sparge) is designed to accept 25 mL of sample with a water column that is at least 12 cm deep. The gaseous headspace of the chamber must be <15-mL total volume.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

5. Autosampler – OI Analytical model 4551, 4552, or equivalent
6. Syringes – 5-mL and 25-mL Luer-Lok gastight syringe
7. Microsyringe – various sizes from 10 to 1000- μ L gastight syringes
8. Glassware
 - a. Class-A Volumetric flasks with ground-glass stopper
 - b. Vials, 1.5 –mL, 15-mL, and 40 mL screw cap, with Teflon™/silicone septa
9. Stainless-steel spatula
10. Mettler top-loading balance, or equivalent, capable of accurately weighing to the nearest 0.01 g
11. Integrating system such as Chrom Perfect® by Justice Laboratory Software, or equivalent. Chrom Perfect® is a data system capable of storing and reintegrating chromatographic data and determining peak areas using a forced baseline, area summation, baseline projection, and performing baseline compensation as required.

Reagents and Standards:

A. Reagents

1. Reagent water – Reagent water is defined as water in which an interferent is not observed at or above the reporting limit for parameters of interest. In general, the reagent water supplied at the taps in the laboratory meets this criterion. If the reagent water does not meet the requirements, see your supervisor for further instructions. Reagent water must be used to prepare all sample dilutions and working standards.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

2. Methanol, P&T grade or equivalent, is used to extract all solid samples for analysis and to prepare all secondary dilution standards required for this method. Store at room temperature.

B. Standards

1. Stock standards

- a. All stock standards are obtained from vendors and must contain paperwork indicating: expiration date of solution, components included, and their concentrations within the solution. The vendor must present this information, as well as an indication of component's purity, for traceability issues.
- b. All stocks are stored in an explosion-proof freezer at -10° to -15°C until the expiration date indicated by the vendor.
- c. Gasoline Calibration Stock Standard– Gasoline standard from Restek Corporation or equivalent. Restek Cat # 30237, concentration certified at 5500-ppm.
- d. 15,000-ppm TFT surrogate stock standard – This standard is utilized to prepare a multi-level surrogate calibration that is required by many methods. Restek Cat #54357.
- e. Matrix Spike Stock Standard – Gasoline standard from Supelco or equivalent. Cat # 47516-U concentration certified at 20,000-ppm. (Alternatively, Restek Cat # 30205, concentration at 50,000-ppm)
- f. Surrogate Stock Standard – This stock is purchased in two versions: 2-component and 1-component.

Revision: 15	Effective date: Sep 16, 2013	Page 9 of 23
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

- (1) 2-component surrogate –Restek Cat# 58097 is utilized for all continuing calibration verification (CCV) standards. Refer to the following list for each component and its concentration in this standard:

<u>Component</u>	<u>Concentration (ppm)</u>
1-Chloro-3-fluorobenzene (1C3FB)	12,500
α,α,α-Trifluorotoluene (TFT)	12,500

- (2) 1-component surrogate –Restek Cat# 58098 is utilized for all sample, blanks, Laboratory Control Standard (LCS), Matrix Spike (MS), Matrix Spike Duplicate (MSD), and calibration injections. Refer to the following list for each component and its concentration in this standard:

<u>Component</u>	<u>Concentration (ppm)</u>
1C3FB	12,500

TFT is utilized as a surrogate on the FID. However, TFT is introduced to the sample during the methanol extraction (see Analyses #1150, 6170, 6130, and 6117). 1C3FB is utilized as the internal standard on the PID.

- g. Custom GRO Retention Time (RT) Marker Stock – Restek cat # 563807, contains 2-methylpentane, C6 (n-hexane), toluene, 1,2,4-TMB, C10 (n-decane), and naphthalene.
- h. Fractionation RT Marker Stock – Restek cat # 30451, using as C8 RT marker during Analysis # 12989 only

2. Secondary dilution standards (intermediates)

- a. Secondary dilution standards are stored in an explosion-proof freezer at -10° to -15°C in Teflon-lined screw-capped vials and expire in 30 days.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

b. 550-ppm gasoline calibration standard B

Prepare by diluting 1.0 mL of gasoline calibration stock standard to a final volume of 10 mL in methanol.

c. 55-ppm gasoline calibration standard A

Prepare by diluting 0.5 mL of gasoline calibration standard B to a final volume of 5 mL in methanol.

d. 75-ppm TFT calibration Standard

Prepare by diluting 0.05 mL of TFT stock standard to a final volume of 10 mL in methanol.

e. 2000-ppm Gasoline Spike Intermediate

Prepare by diluting 1.0 mL of gasoline matrix spike stock to a final volume of 10 mL in methanol.

f. 75-ppm Surrogate intermediate standard (either 1- or 2-component stock standard)

Prepare by diluting 300 µL of surrogate stock to a final volume of 50 mL in methanol.

g. 750-ppm TFT Intermediate for Methanol Preserves/Extraction

Prepare by diluting 500 µL of TFT stock to a final volume of 10 mL in methanol.

h. 750-ppb TFT Methanol Extraction Solution

- (1) Prepare by diluting 2 mL of TFT Intermediate for methanol Preserves to a final volume of 2000 mL in methanol.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

- (2) This final methanol extraction solution is then analyzed on a GC system by taking 2 mL of this standard, with 20 µL of 1-component surrogate, and add to reagent water to a final volume of 50 mL.
- (3) After analyzing the surrogate recovery is then reviewed against the statistically derived surrogate recovery windows. If the % recovery is within the acceptable windows, the solution is then used to extract blanks, LCS, and samples. If the % recovery is outside of acceptable windows, the solution is discarded and reprepared.

i. RT Marker Intermediate

Prepare by diluting 1 mL of RT stock to a final volume of 10 mL in methanol. This has an expiration date of 6 months from opening of ampule.

j. Fractionation RT marker intermediate

Prepare by diluting 1 mL of fractionation RT stock to final volume of 10 mL in methanol. This has an expiration date of 6 months from opening of ampule.

3. Working standards

- a. Aqueous standards, made from the secondary dilutions, are stored at 0° to 6°C, not frozen, prepared each day of use, and expire in 24 hours unless otherwise noted. They are transferred into 40mL vials for analysis without headspace.

Revision: 15	Effective date: Sep 16, 2013	Page 12 of 23
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

- b. Calibration Standards—All calibration standards are prepared in 50-mL volumetric flasks, by diluting the appropriate volume of the methanolic working standard with 20 μ L 1-Component Surrogate and 2 mL methanol. (See Table I for volumes used for initial calibration standard preparation and for values of each calibration level.)
- c. Method Detection Limit (MDL) – Add 8 μ L of the gasoline calibration standard B and 80 μ L of 2-Component Surrogate, into a 500-mL volumetric flask. Add 8 mL methanol and bring to a volume with reagent water yielding the MDL standard concentration at approximately 22 ppb.
- d. Initial Calibration Verification (ICV) – Add 22 μ L of gasoline spike intermediate and 40 μ L of 2-Component Surrogate into a 100-mL volumetric flask. Add 4 mL of methanol and bring to volume with reagent water yielding the ICV concentration at approximately 440 ppb.
- e. Continuing Calibration Verification (CCV) standards
 - (1) Add 80 μ L of gasoline standard and 80 μ L of 2-Component surrogate into a 200-mL volumetric flask. Add 8 mL methanol and bring up to volume with reagent water yielding the CCV at approximately 220 ppb.
 - (2) The CCV concentration can vary based on set client requirements (refer to project notes).
- f. RT Marker
 - (1) Add 100 μ L of the marker intermediate and 80 μ L of 2 component surrogate into a 200-mL volumetric flask. Add 8 mL methanol and bring up to volume with reagent water.
 - (2) The retention time marker working standards expire in 14 days from the prep date.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

g. C8 Marker

- (1) Add 100 µL of the fractionation RT marker intermediate and 80 µL of 2 component surrogate into a 200-mL volumetric flask. Add 8 mL methanol and bring up to volume with reagent water.
- (2) The expiration date is 14 days from the prep date.

Instrument Operating Conditions:

Below are the suggested operating conditions for the autosamplers, purge and traps, and gas chromatograph.

1. O.I. 4551 autosampler or Archon autosampler

Cool flow and chiller temperature	4°C
Rinses between samples	2
Needle depth	85% (OI only)

2. O.I. 4560 Concentrator or Tekmar LSC3000

Sample volume	25 mL
Purge	11 minutes at ambient temperature
Purge gas	He/N2 at ~40 mL/min
Sorbent trap	Tenax trap or equivalent
Desorb	Preheat to 180°C; desorb at 180°C for 4 min
Bake	10 minutes at 180°C

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

3. HP 5890 II Gas Chromatograph

Injector	Low dead volume injector – 220°C
Detector	FID at 250°C
GC oven	Start at 40°C and hold for 0.5 min; Ramp at 15°C/min to 140°C; Ramp at 5°C/min to 160°C; Ramp at 30°C/min to 250°C and hold for 5 min.

NOTE: Alternate parameters may be utilized, to optimize the chromatography. All QC criteria must be met, as well as maintaining proper separation and sensitivity.

4. FID gases

Column and make-up (He)	30 ± 2 mL/min
H ₂ gas	35 ± 2 mL/min
Air	160 ± 5 mL/min

NOTE: Flows can be altered in order to optimize detector response.

Calibration:

- A. Prior to calibration or analyzing samples utilizing the autosampler, make sure that the following is complete:
1. The autosampler is programmed and functioning properly.
 2. Set the P&T and GC to the conditions specified under the Instrument Conditions section of this method. Program autosampler to start and end on the appropriate vials, then press “START.”

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

B. Retention Time Window

1. The gasoline range begins 0.1 minutes before the peak apex of marker compound for the start of the range, and ends 0.1 minute past the peak apex of marker compound for the end of the range. The retention times are determined by analyzing a retention time marker standard before every initial calibration and batch

2. Retention Time (RT) windows are established for the retention time marker hydrocarbons and surrogate by using ± 3 standard deviation from the mean retention time for three standards injected over a 72-hour period. These marker hydrocarbons are used to determine the starting and stopping points for the GRO range to be quantitated. If the RTs for the continuing GRO standard fall outside the RT windows, update the hydrocarbon(s) midpoint retention times using that standard, the window stays the same. Also update the start and stop times used for the GRO range using the same standard. If RTs are not consistent, the cause must be investigated and corrective action taken.

C. Initial Calibration

1. The 5-point calibration (see Table I) is analyzed with gasoline concentrations ranging from approximately 27.5 to 1100 ppb (dependent on gasoline stock standard concentration). The surrogate concentration must also increase with increasing standard concentration.

2. Calibration is performed using the external standard method for FID detection.
 - a. A calibration factor (CF) is calculated for each calibration level. See calculation section of this procedure.

 - b. Area contributed by the surrogates is not included in the total gasoline area.

Revision: 15	Effective date: Sep 16, 2013	Page 16 of 23
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

3. The percent relative standard deviation (%RSD) of the calibration factor must be $\leq 20\%$ to assume linearity through the origin and use the average calibration factor (AVGCF) for quantitation. For OA-1, the correlation coefficient must be 0.995 or greater.
4. If the %RSD is $>20\%$, a linear or quadratic calibration may be used in place of the average calibration factor as long as the correlation coefficient is greater than 0.99. At least 6 calibration levels must be utilized for a quadratic fit.
5. An ICV standard is also analyzed and must meet the same criteria established by the method. This criteria is $\pm 15\%$ difference for all scans except scan #10599 where the criteria is $\pm 20\%$.
6. An MDL standard must be analyzed with every initial calibration. GRO must be visible for the standard to be acceptable
7. Instrument Blanks (IBLK) are analyzed to ensure the analytical system is free of contamination. Additional clean up blanks can be run as needed based on system performance.

D. Continuing Calibration Verification (CCV)

1. Prepare and analyze a CCV to ensure that the instrument is functioning correctly and that the calibration is valid.
2. The calibration curve is verified every 12 hours (or every ten field samples when run with PID in series, or if a client requires this frequency).

A field sample is defined as any client submitted sample, matrix spike, or matrix spike duplicate sample. Blanks, LCS, and batch MS/MSD are NOT considered field samples.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

3. The CCV standard criteria established by the method is $\pm 15\%$ difference for the calculated concentration versus the nominal concentration for all scans except Analysis #10599 where the criteria is $\pm 20\%$.
4. Samples must be bracketed by acceptable CCVs, otherwise samples must be reanalyzed.
5. If the bracketing CCV fails requirements with a positive trend and GRO was below the reporting limit in the samples, then no re-analysis is required.
6. If the recovery of the GRO concentration is outside of the acceptable range, the CCV is repeated with freshly made standards.
 - a. If the GRO concentration is within the acceptable range on the repeat, the standard is acceptable.
 - b. If the freshly made CCVs fails and the problem appears to be instrument related, proper maintenance must be performed on the instrument that corrects the problem.
 - (1) Having failed two previous CCVs, a series of two freshly made CCVs must now be analyzed and both must be within the acceptance criteria before continuing with sample analysis.
 - (2) The samples associated with the failed standards must be repeated after passing CCVs.
 - c. If the GRO concentration is still outside the acceptable range on the repeats, the system is recalibrated.
 - d. All data must have an in-specification CCVs preceding it to be considered valid. If one CCV fails, but the second one passes, the samples still need to be repeated under the passing CCV.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

Procedure:

A. Prior to analyzing samples utilizing the autosampler, make sure that the following is complete:

1. The autosampler is programmed and functioning properly.
2. Set the P&T and GC to the conditions specified under the Instrument Conditions section of this method. Program autosampler to start and end on the appropriate vials, then press "START."
3. If the system has not been calibrated, then calibrate the system (refer back to the calibration section).

B. Samples are analyzed by adding 2 mL of the sample's methanolic extract to reagent water and 20 µL of 1-component surrogate) in a 50-mL volumetric flask. Bring up to volume with reagent water. Pour into a 40-mL vial for sampling via the autosampler.

1. TFT surrogate is introduced to the sample during the methanol extraction (refer to Analyses #1150, 6170, 6130, and 6117).
2. If the prescreen of the extract indicates high levels of organics, a dilution must be made. When preparing dilutions, a constant amount of methanol (i.e., 1:25) must be maintained.

Example: If a sample is to be analyzed at a dilution factor (df) of 250, 200 µL of the sample's extract and 1.8 mL of methanol are injected into reagent water in the 50-mL volumetric flask with 20 µL of 1-Component Surrogate.

C. Prepare a batch sequence. A batch can consist of up to 20 field samples and must contain a method blank, a laboratory control spike, and either a matrix spike/matrix spike duplicate when sufficient sample is available, or a laboratory control spike duplicate.

Revision: 15	Effective date: Sep 16, 2013	Page 19 of 23
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

- D. Samples must be bracketed by acceptable check standards, otherwise samples must be reanalyzed.
- E. The total peak area (excluding the surrogate area) between the defined start and stop of the GRO range is used to calculate the concentration of GRO.
- F. If the concentration of the analyte recovered in the sample exceeds the concentration of the highest level of the calibration, the sample must be repeated at a higher dilution.
- G. The analyst must determine if carryover is present after an analysis of a sample containing high levels of analytes. It may be necessary to analyze a instrument blank to ascertain that all analytes are below the method detection limit. If they are not, the instrument blank is repeated until the system is acceptable. Refer to 1-P-QM-PRO-9015470, for more instruction on this.

Calculations:

The peak area summation of the entire gasoline pattern, excluding any surrogates and retention time markers, calculated with the dilution factor and the calibration factor will establish the concentration of GRO in the sample.

1. Calculation of GRO in a sample:

$$Conc (ppm) = \frac{Ar}{CF} \times \frac{Vt}{Wt} \times DF$$

Where:

- Ar = Area for the GRO in the sample
- CF = Calibration factor
- DF = Dilution factor (default of 25)
- Wt = Weight of sample in extraction (default 10 g)
- Vt = Total volume of MeOH during extraction (default 10 mL)

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

2. Calibration Factor (CF)

$$CF = \frac{\text{Total Area}}{\text{Concentration } (\mu\text{g} / \text{L})}$$

3. The RPD is calculated as follows:

$$RPD = \left[\frac{MS \text{ Concentration} - MSD \text{ Concentration}}{MS \text{ Concentration} + MSD \text{ Concentration}} \right] \times 100$$

4. Refer to 1-P-QM-PRO-9015491, for further details on calculations.

Statistical Information/Method Performance:

Generate method detection limits (MDLs) and limits of quantitation (LOQs) according to 1-P-QM-QMA-9017309. Perform an MDL study on each instrument used for the analysis. Determine the MDL by taking seven spiked replicates through the entire extraction and analysis procedure. Compare and pool results to determine the final reporting MDL. The department supervisor maintains annual study data. The department supervisor requests that a QA Specialist update to the LIMS as needed. Update the department database via a download from the LIMS.

Quality Assurance/Quality Control:

- A. Each batch (up to 20 samples) must contain a method blank, LCS, and either an unspiked background sample (US)/MS/MSD or an LCS/LCSD.
 - 1. Method Blank – The method blank is analyzed once per 24 hours and is examined for possible contamination. All compounds must be less than the reporting limit of the project. If the blank values exceed these values, corrective action must be taken and the method blank reanalyzed until the criteria are met.

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

- a. Prepare by adding 10 grams of clean sand into a 40-mL vial and extracting it with 10 mL of TFT for Methanol Extraction.
 - b. Then take 2 mL of this extract with 20 µL of 1-component surrogate and add to reagent water to a final volume of 50 mL.
 - c. The solution is then poured into 40-mL vials with screw-top Teflon-lined septa for use in the autosampler.
2. Surrogates – α,α,α -trifluorotoluene is the reported surrogate. Surrogate recovery is acceptable if the percent recovery is within the statistically derived windows. Lower recoveries are expected in diluted samples. If the surrogate recovery falls outside the acceptance window, re-extract the sample (if possible) and/or repeat the analysis. If the repeat is out of specification, report the original results and comment about the effect of the matrix on the surrogate. If the surrogate is within specifications on the repeat analysis, report the results from the repeat analysis.
 3. MS and MSD—For each set of 20 field samples, extract one in triplicate, spiking the duplicate and triplicate with 55 µL of gasoline spike intermediate into sample extract. These are then diluted and analyzed as a normal sample. Approximate concentration of this standard is 11 mg/kg.
 - a. Results of the MS/MSD are compared to the QC limits that are statistically derived.
 - b. The maximum RPD (relative percent difference) allowed between the MS and MSD is 30%.
 - c. If any of the MS/MSD criteria fails, then an LCS is used to verify that the system is within specifications

 Lancaster Laboratories Environmental	Document Title: Gasoline Range Organics (GRO) in Soils using Purge and Trap Gas Chromatography by SW-846, Method 8015B or SW-846, Method 8015C, or SW-846, Method 8015D	Eurofins Document Reference: 1-P-QM-WI -9015132
--	---	--

4. LCS/ LCSD is prepared by adding 10 grams of clean sand to a 40-mL vial and adding 10 mL of TFT for methanol extraction. Spike the extraction with 55 µL of gasoline spike intermediate. Then take 2 mL of this extract with 20 µL of 1-Component Surrogate and add reagent water to a final volume of 50 mL. Approximate concentration of this standard is 440 µg/kg.

- a. If the LCS does not meet criteria, corrective action must be taken, including repeating the batch.

Corrective action may include instrument maintenance, re-analysis of samples, or data qualification.

- b. If sufficient sample is not available to perform MS/MSD, LCS/LCSD are analyzed and must meet QC criteria.

B. QC limits for surrogates, LCS/LCSD, and MS/MSD are established through statistical analysis of historical data. The limits are evaluated every 6 months and updated as needed. The limits are maintained in the LIMS for the relevant analysis numbers.

Table I
Calibration Standards

Cal Level	Amt. Gasoline (µL)	Amt. TFT (µL)	Gas Conc. (µg/kg)*	TFT Conc. (µg/kg)
1	25 (A)	5	27.5	7.5
2	100 (A)	10	110	15
3	20 (B)	20	220	30
4	50 (B)	30	550	45
5	100 (B)	40	1110	60

* Based upon 5500-ppm gasoline stock and a 15,000-ppm TFT stock.

No. L-34

SOP 10 – Laboratory Tissue Homogenization

**Standard Operating Procedure
No. 10**

**Laboratory Tissue
Homogenization**

August 2015

Revision 0

1. Purpose and Scope	3
2. Procedures	3
2.1 Equipment List	4
2.2 Equipment Decontamination and Calibration Procedures	4
2.3 Tissue Homogenizing Procedure	6
3. Quality Assurance	6
4. Documentation	7
5. References	7

1. Purpose and Scope

The purpose of this document is to define the standard operating procedure (SOP) for homogenizing tissue samples from the Newark Bay Study Area for analysis at the analytical laboratory. Tissue samples will be analyzed for constituents as outlined in the Newark Bay Study Area Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP). This SOP is based on, and is in general accordance with, the methods used on the Lower Passaic River Restoration Project Cooperating Parties Group Quality Assurance Project Plan, Fish and Decapod Crustacean Tissue Collection for Chemical Analysis and Fish Community Survey (Windward 2009).

This SOP may change depending upon equipment limitations or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s Facility Coordinator and the United States Environmental Protection Agency Remedial Project Manager. The ultimate procedure employed will be documented in the laboratory notebook.

Other SOPs will be utilized with this procedure, including:

- SOP No. 4 – Management and Disposal of Residuals
- SOP No. 5 – Containers, Preservation, Handling, and Tracking of Samples for Analysis
- SOP No. 8 - Documenting Field Activities

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Procedures

Following the conclusion of the 28-day bioaccumulation study in the analytical laboratory using the polychaete worm, *Nereis virens*, composite worm tissue samples will be prepared for each sample location. Tissue samples will be homogenized in a food processor and blended to achieve acceptable homogenization prior to analysis. Homogenization will occur in a timely manner to meet the specified holding times documented in the SQT QAPP.

The following procedures will be used to homogenize tissue samples.

2.1 Equipment List

The following equipment list contains materials that may be needed to perform the procedures outlined in this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment not listed here may be required dependent on field conditions.

- food processor with titanium blade and glass bowl
- Teflon®-coated spatula
- talc-free polyvinyl chloride (PVC) gloves
- electronic balance with calibration weights (checked for accuracy at least daily, and documented in accordance with laboratory protocols)
- labeled sample jars
- laboratory logbook or individual bench sheet forms
- bristle brushes
- wash/rinse tubs
- low-phosphate detergent
- 10% nitric acid, ultra pure
- acetone, methanol, and hexane (pesticide grade or better in separate Teflon® bottles), as necessary
- deionized “analyte free” water
- tap water (from any treated municipal water supply).

2.2 Equipment Decontamination and Calibration Procedures

The following steps will be used to decontaminate sample homogenization equipment that will come into contact with tissue designated for chemical analysis (e.g., food processor bowl, food processor blade, and Teflon®-coated spatula). Decontamination of laboratory homogenization equipment will occur prior to initial use and again between homogenization of each tissue sample.

1. Personnel will dress in suitable protective equipment to reduce exposure to chemicals and contaminants per laboratory health and safety SOPs.
2. Prior to start of tissue processing, all laboratory glassware and instruments will be cleaned per the steps outlined below. Decontamination of equipment will occur again between each tissue composite homogenized using the equipment, to minimize the likelihood of cross contamination from one tissue sample to another. Decontamination taking place between tissue samples being homogenized will begin with residual sample media being scraped off and the equipment rinsed with tap water.
3. Equipment will be placed in a wash tub or bucket containing Alconox (or other low-phosphate detergent) in tap water, and scrubbed with a bristle brush or similar utensil. Equipment will be rinsed with tap water in a second wash tub or bucket, followed by a nitric acid rinse, a deionized "analyte free" water rinse, a methanol rinse followed by a hexane rinse, and lastly with a deionized water rinse. Rinses shall utilize sufficient amounts of solvent/water to flush rather than just wet the surface. The volume of deionized water used during the rinse must be at least five times the volume of solvent used.
4. Following decontamination, equipment will be placed in a clean area and allowed to air dry.
5. Used decontamination water will be collected and handled in accordance with residuals management procedures outlined in SOP No. 4 – Management and Disposal of Residuals or alternatively in accordance with the laboratory's established protocols.
6. A calibrated laboratory electronic balance capable of reading to 0.1 grams will be used to measure the homogenized tissue.
7. At the start of each sample homogenizing day, the designated laboratory's electronic balance will be calibrated using certified sample weights. The target calibration weight mass will be recorded in the laboratory logbook. The electronic balance will be tared to zero and the calibration weight will be measured using the electronic balance. The mass will be recorded in the laboratory logbook and if within the specified tolerances set by the manufacturer, then no adjustments will be made. If the measured weight falls outside of the tolerances, then a calibration adjustment will be made to the electronic balance following the manufacturer's specifications and/or procedures.

2.3 Tissue Homogenizing Procedure

Tissue homogenizing will adhere to the following procedures:

1. Personal protective equipment will be donned and procedures will be reviewed prior to performing tissue homogenization. Talc-free PVC gloves must be worn throughout the homogenization procedure.
2. Tissue samples will be retrieved from laboratory frozen (-15 degrees Celsius [°C]) storage prior to homogenization with sufficient time allowed for tissue to partially thaw before homogenizing.
3. After the tissue sample has partially thawed, use the Teflon®-coated spatula to place the tissue in a decontaminated processor. Remove as much of the processed tissue in the sample jar as possible to maximize the tissue mass available for analysis post-homogenization. Using the processor, grind the sample until it appears to be fully and consistently homogenized and there are no large chunks.
4. Place the homogenized sample into the appropriate pre-weighed, pre-cleaned glass jars using the Teflon®-coated spatula. Again, every effort shall be made to remove as much of the homogenized tissue in the food processor as possible to maximize the tissue mass available for analysis post-homogenization. If necessary, the laboratory will segregate homogenized samples for distribution to other analytical laboratories. Record weights of homogenized samples and glass jars. If the samples will not be extracted/digested immediately, the samples must be placed back into the freezer (-15°C) until analytical work commences. Record placement of the samples in the freezer storage logbook. Note return of the samples to the Internal Tracking chain of custody.
5. All utensils and equipment must be washed in-between samples according to the procedures described previously in Section 2.2.
6. Repeat Steps 3 through 5 until all of the samples are homogenized.

3. Quality Assurance

The following quality assurance/quality control procedures will be performed during sample homogenization:

1. All pertinent field information and chains of custody (COCs) will be provided to the sample processing team. The designated laboratory personnel will review the sample information and confirm that the number of individuals, collection date(s),

collection time(s), species, and required tissue analyses match the COCs. If any questions arise, the laboratory personnel will contact the project manager and laboratory project manager to resolve.

2. Laboratory logbook will be checked between tissue processing and homogenizing steps to make sure required information is completed per the next section.
3. Rinse blanks will be collected once per decontamination event (not to exceed 1 per day), to measure the effectiveness of the equipment cleaning procedures. A rinse blank will be collected for all determinative analyses, with the exception of % lipids and % moisture. The rinse blanks will be collected by pouring contaminate-free reagent water over the homogenization equipment after completion of the cleaning procedure detailed in Section 2.2. The water will be collected in an appropriate container with the appropriate preservative and labeled, as specified in SOP No. 5 – Containers, Preservation, Handling, and Tracking of Samples for Analysis.

4. Documentation

Sample measurements and observations will be noted in the laboratory logbook or on individual bench sheets. Information to be recorded in the laboratory logbook will include, at a minimum:

- responsible person's name
- dates and times of activities
- sample IDs
- tissue weights (both individual and total sample).

IDENTIFICATION AND ENUMERATION OF MACROINVERTEBRATES

1.0 PURPOSE

This procedure is provided to ensure a high level of accuracy and consistency regarding identification and enumeration of macroinvertebrates.

2.0 SCOPE

This procedure is applicable to the identification and enumeration of macroinvertebrates and applies to personnel who identify macroinvertebrates.

3.0 DEFINITIONS

- 3.1 **Trained personnel** refers to biologists who have acquired experience in macroinvertebrate identification through academic study or training, and have demonstrated the ability to independently make accurate identifications.
- 3.2 **Taxonomic expert** refers to a recognized authority in identifying macroinvertebrates through description of species and/or publication of keys and other taxonomic literature.

4.0 REFERENCES

- 4.1 *Corporate Health & Safety document (current revision).*
- 4.2 USEPA. 1973. Biological field and laboratory methods. EPA-670/4-73-001.

5.0 SAFETY PRECAUTIONS

Observe appropriate laboratory safety precautions given per Reference 4.1. Handle noxious or toxic preservatives, mounting media, and clearing agents per precautions provided in MSDS sheets (e.g., wear personal eye and skin protective gear, and use these materials in well ventilated areas such as outside, under a fume hood, or with other ventilation system). Contact the Invertebrate Section Supervisor for MSDS's and required personal protective gear. **NOTE:** Formalin/formalin products normally are neither required, nor are they to be used in the conduct of this procedure. In the unlikely event formalin is required (client specified) or encountered, contact the Section Supervisor before proceeding with specimen identification and enumeration.

6.0 APPARATUS

The following equipment (or equivalent) as applicable is needed:

- 6.1 Dissecting microscope with 10-20x oculars and variable magnifications (at least 8-10x), stage micrometer, and ocular micrometer.
- 6.2 Tensor lamp.
- 6.3 Compound microscope (1000x and internal light source).
- 6.4 Forceps.
- 6.5 Dissecting needles.
- 6.6 Flat-bottomed Syracuse or petri dishes.

- 6.7 Preservatives (e.g., isopropanol and ethanol).
- 6.8 Clear plastic ruler (mm graduations).
- 6.9 Glass slides.
- 6.10 Cover slips.
- 6.11 *Hot plate*.
- 6.12 Clearing agents for chironomids and oligochaetes (e.g., Amman's lactophenol and 10% potassium hydroxide).
- 6.13 Euparal for permanent slide mounts.
- 6.14 Appropriate taxonomic keys.
- 6.15 Bench/data sheets (see Attachment I for example).
- 6.16 Mettler balance.
- 6.17 Air filtration system (e.g., Ecologizer) or hood, and personal protective gear.

7.0 INSTRUCTIONS

- 7.1 Identification requiring dissecting microscope only.
 - 7.1.1 Pour vial specimens into a petri or Syracuse dish, and examine with the dissecting microscope.
 - 7.1.2 If necessary, segregate morphologically similar specimens into groups.
 - 7.1.3 If any taxon or group contains too many individuals as to make identification of all of them impractical, randomly subsample each as allowed per study specifications.
 - 7.1.4 Select the proper key and identify the specimen(s) to the lowest practicable taxonomic level (or per client specifications).
 - 7.1.5 Record the identification of each taxon and number of specimens by taxon on the bench sheet. Additional information to be recorded on the bench sheet includes project name, sample location, date, identifying biologist, pertinent sub-sampling information, and applicable taxonomic notes.
 - 7.1.6 Return specimens to the vial and add preservative. **NOTE: If specimens are to be weighed by individual taxon, be sure that each vial contains only one taxon. If necessary, add a label bearing the specimen(s) name.**
- 7.2 Identification requiring both dissecting and compound microscopes. **NOTE: Chironomid larvae and oligochaetes require special preparation for viewing with a compound microscope. Clear chironomid larvae by placing them in a 10% KOH solution until the head capsule is transparent. Clear oligochaetes in Amman's Lactophenol until the body is translucent. Gentle application of heat will aid the clearing process.**
 - 7.2.1 Follow instructions 7.1.1 through 7.1.4 until key characters become too small to be observed clearly (e.g., mouthparts of Chironomidae spp.).
 - 7.2.2 Using a glass slide, mounting media, and cover slip make a slide mount of the specimen(s) requiring further magnification.
 - 7.2.3 Continue with the appropriate taxonomic key using the compound microscope, and identify the specimen to the lowest practicable level.
 - 7.2.4 Follow instructions 7.1.5 and 7.1.6.

8.0 QUALITY CONTROL

- 8.1 Macroinvertebrate identification and enumeration shall be conducted only by personnel experienced or trained in appropriate techniques.
- 8.2 Maintain a reference collection of all taxa (if applicable) identified for a particular study. Taxa will be properly labeled with name, date, location of collection, reference number, life stage, taxonomic reference, and identifying biologist.
- 8.3 Current taxonomic literature will be used and keys updated as appropriate.
- 8.4 Interchange of taxonomic opinion among in-house biologists will ensure consistency and agreement in identification. QC checks of identification accuracy will be made by a second biologist who will re-identify 10% of the samples (minimum 1 sample) *from consecutive batches of 10. A sample will be re-identified from those analyzed by each biologist that worked on the project.* Samples selected for QC should represent a majority of the taxa identified for a particular collection. Each taxon from the selected sample will be either verified or rejected by the second identifier. In cases where identification is rejected, each biologist shall compare their respective criteria and attempt to *correct* the identity of the taxon. If this effort fails, the identification shall be moved to *the taxonomic level, where agreement is reached. By selecting QA/QC samples from consecutive batches, corrections made to the first batch can be more easily applied to subsequent ones.*
- 8.5 *A data set is considered sufficiently accurate when 90.0 percent of the original identifications and taxa counts are confirmed by a second biologist. Original gross counts (the sample total) must be within 90 percent of the QA/QC count. If a sample fails either criterion, another (one containing a majority of the taxa) is selected from the same batch of 10 and re-identified. If the second sample passes, corrections can be limited to those taxa that were found to be in error (from both samples). If the second sample fails, all samples from that batch of 10 analyzed by the first biologist need to be re-examined.*
- 8.6 *Specimens representing state or federally “endangered”, “threatened”, or “species of special concern (e.g., freshwater mollusks)” taxa will be sent (as applicable) to taxonomic experts for verification.*
- 8.7 *Quality Control results will be logged on the respective Bench Sheets produced from the sample analysis and any taxonomic changes noted. All data tables and narrative reports produced for each study should be checked for transcriptions, spelling, and calculation errors by a second biologist.*
- 8.8 *Where project specific protocols provided to Normandeau differ from this in-house procedure, the analyses and Quality Assurance/Quality Control shall be conducted according to client specifications.*

9.0 REPORTING

Report the completion of specimen identification as per study specifications.

10.0 RECORDS

Retain the following records in the laboratory per study specifications. In lieu of such, records shall be retained for a period of at least three (3) years following completion of a given study.

- Laboratory Bench sheets and Sample Processing forms (including QC identification records)
- Reference collection
- Copies of reports generated by Section 9.0
- Personnel training records
- *QA/QC log including sample numbers, biologist names, and results (as per study specifications)*

SORTING OF MACROINVERTEBRATES FROM SAMPLE RESIDUE

1.0 PURPOSE

This procedure describes the instructions for sorting macroinvertebrates from sample residue.

2.0 SCOPE

2.1 This procedure is applicable to the separation of macroinvertebrates from sample residue.

2.2 This procedure applies to personnel who sort macroinvertebrates.

3.0 DEFINITIONS

Macroinvertebrates refers to animals that are large enough to be seen by the unaided eye (*can be retained by 0.595-mm mesh*) (US EPA 1973), and spend part or all of their life cycles upon or within aquatic substrates.

4.0 REFERENCES

4.1 Corporate Health and Safety document (current revision).

4.2 US EPA. 1973. Biological field and laboratory methods (EPA-670/4-73-001).

4.3 US EPA. 1999. *Rapid bioassessment protocols for use in wadeable streams and rivers (EPA 841-B-99-002)*.

4.4 NAI Procedure EA9 "Macroinvertebrate Sample Sub-sampling".

5.0 SAFETY PRECAUTIONS

Observe appropriate laboratory safety precautions given per Reference 4.1. Handle noxious or toxic preservatives (e.g., *ethanol*, isopropanol, formalin, stains) in well-ventilated areas (e.g., outside, under a fume hood, or other ventilation system). See appropriate Material Safety Data Sheets (MSDS) before using any of these materials, and wear eye and skin protective gear. Avoid the use of formalin/formalin products whenever possible. Contact the Project Manager or Invertebrate Section Leader regarding *training for the use of formalin*, for MSDS's, and required personal protection gear.

6.0 APPARATUS

The following equipment (or equivalent) as applicable is needed.

6.1 White enamel sorting pans or white plastic photo developing trays.

6.2 Tensor lamp.

6.3 Preservative (e.g., 70% isopropanol *or ethanol*) and water.

6.4 Specimen vials of several sizes.

6.5 Forceps.

6.6 Sieves (mesh size is study specific; those commonly used include 0.350, 0.500, & 0.595 mm).

6.7 Tablespoon.

6.8 Mechanical counters.

6.9 Sample processing sheets.

6.10 Labels

6.11 Pencil or pen (indelible ink)

6.12 Rubber bands.

6.13 Fume hood.

6.14 *Dissecting Scope*

7.0 PRELIMINARY INSTRUCTIONS

If preliminary observation or initial sorting indicates that a sample contains so many macroinvertebrates that whole sample sorting is impractical, subsample the residue (see Reference 4.3) as instructed by the Project Manager (or as per study specifications).

8.0 INSTRUCTIONS PROPER

All sorting shall be done by trained personnel. Samples are prepared and examined per study specifications (e.g., stained, examined with or without magnification, etc.) detailed on the Analytical Request Form (Enclosure 1). Obtain this form from the Project Manager or Invertebrate Section Leader, prior to sorting any sample/sample set.

- 8.1 Wash/rinse sample residue (with tap water), in a sieve of mesh size detailed on the Analytical Request Form, to remove/dilute the remaining preservative.
- 8.2 Place one to several (depending on how difficult it is to discern macroinvertebrates from the residue) tablespoonfuls of residue into a sorting pan filled with about 2 cm of water.
- 8.3 Hand-pick macroinvertebrates with forceps until no more specimens can be found.
- 8.4 Place sorted macroinvertebrates in specimen vials *containing preservative*. Separate by vial the different types (taxa) to the extent possible, and maintain counts for each vial using mechanical counters.
- 8.5 If the sorted residue is to be retained, return it to the storage container; otherwise discard.
- 8.6 Repeat Instructions 8.2-8.5 until the entire sample is sorted.
- 8.7 If applicable, properly preserve, label, and store the retained residue.
- 8.8 Attach a sample identification label to each vial. The label should at least be cross-referenced to the original sample by date, location, replicate number and client/project number (as necessary).
- 8.9 Rubber-band together all sample specimen vials.
- 8.10 Place the banded sample vials in the appropriate area for identification.
- 8.11 Complete sample processing forms (record all pertinent sub-sampling and other information) and file.
- 8.12 *If study objectives call for a fixed-count (ex. 100, 200, or 300 specimen) sub-sample follow the guidelines given in US EPA (1999).*

9.0 QUALITY CONTROL

- 9.1 Sorting macroinvertebrates from sample residue shall be conducted only by personnel trained in sorting techniques.
- 9.2 Chain-of-Custody forms shall be used for submittal of samples collected by non-Normandeau personnel to insure sample integrity from the time collected until received at the laboratory.

- 9.3 Sorting efficiency shall be monitored by the Project Manager or Section Leader per client specifications. In lieu of client specified protocols, sorting efficiency will be determined by re-sorting the residue from *one* (randomly selected) of *each batch of ten samples* (with a minimum of 1 sample) for each sample collection date. If efficiency (either number of taxa or individuals removed during the first sorting effort) is below *90%* for any QC sample, a second sample shall be selected. If efficiency remains below *90%*, all samples sorted by that technician *for the particular batch* will be re-sorted. Retraining shall be conducted for any technician whose sorting efficiency is below *90%* on two consecutive QC samples.
- 9.4 All sample residues retained per client specifications, will be properly preserved and labeled.
- 9.5 All sorted macroinvertebrates will be properly preserved and labeled.
- 9.6 Sample processing forms shall be completed accurately and recorded information legible.
- 9.7 *Use of magnification is recommended for samples collected with a mesh size less than 0.595 mm.*

10.0 REPORTING

The Project Manager or Invertebrate Section Leader will report the completion of sorting per study specifications, as applicable.

11.0 RECORDS

Retain the following records in the laboratory responsible for sorting the samples, per study specifications. In lieu of such, records shall be retained for a period of at least three (3) years following completion of a given study.

- Sample processing forms, including sorting efficiency results.
- Analytical Request and applicable Chain-of-Custody forms.
- Personnel training records.

12.0 ATTACHMENTS

See the Project Manager or Invertebrate Section Leader for the latest revision of the following forms:

- 1 Analytical Request Form—Example
- 2 Chain-of Custody Form---Example. (This form is to be provided to clients/subcontractors who independently collect and submit macroinvertebrate samples for analysis. This form is not required for samples collected and delivered to the Invertebrate Laboratory by Normandeau personnel.)
- 3 Laboratory Processing Form---Example

**Sediment Bioaccumulation Test with a Polychaete Species
PROTOCOL PS-BIO-03-T**

SEDIMENT BIOACCUMULATION TEST WITH A POLYCHAETE SPECIES

1. TEST OBJECTIVE

To assess the toxicity and bioaccumulative effects of a whole sediment sample to a polychaete species.

1.1 Detection Limits

Detection limits of the toxicity of a sediment or chemical are organism dependent.

1.2 Definitions

Refer to Appendix A of EA SOP Manual (EA 2013).

2. INTERFERENCES

Improperly cleaned glassware and sampling equipment can add toxicity to sediment. Improper sample collection, handling and storage also can affect the bioavailability of contaminants in sediment. Sediment grain size and texture may influence the response of test organisms. Test temperature and the addition of food, water or solvents to the test chambers may alter bioavailability of toxicants. Excess food can promote the growth of bacteria. The presence of indigenous organisms in the sediment may affect survival or growth of test organisms and confound test results. Other naturally occurring chemical characteristics such as ammonia and sulfide can modify organism response.

3. TEST EQUIPMENT

- 3.1** Environmental chamber capable of maintaining target test temperature, lighting and photoperiod.
- 3.2** Glassware (large diameter pipets, beakers, aquaria)
- 3.3** Meters capable of measuring temperature, pH, dissolved oxygen and conductivity/salinity
- 3.4** Oil free air supply to aerate overlying water.
- 3.5** Aeration equipment with glass pipets
- 3.6** Siphon bulb
- 3.7** Forceps
- 3.8** Sieve

4. CALIBRATION

Refer to Section 10 of EA SOP Manual (EA 2013).

5. TEST ARTICLE

5.1 Description/Identification

The test article is a whole sediment sample.

5.2 Sample Preparation

Depending upon the project, the sediment may be screened through a suitably sized sieve to remove large particles and indigenous organisms, and homogenized before being placed in the test chambers. Sediment and overlying water will be added to test vessels seven days prior to introduction of test organisms in order to allow suspended sediments to settle.

6. EXPERIMENTAL DESIGN

6.1 Test Organisms

6.1.1 Species

The test species is a polychaete species, as specified by the project study plan. Commonly tested polychaete species include *Nereis virens* (sand worm) and *Neanthes arenaceodentata*. Selection of test species is dependent on project-specific requirements.

6.1.2 Source

The polychaete organisms used for toxicity tests are obtained from a biological supplier or field collected as specified in the final report.

6.1.3 Holding Conditions

Upon receipt at EA's Culture Facility, the organisms may be transferred to holding tanks of artificial seawater or held in moist newspapers and seaweed. Prior to use in testing, organisms are gradually acclimated to testing conditions. During the holding period, dead or unhealthy organisms are removed as observed and recorded on appropriate log sheets as part of the quality control program. Certain regulatory or project specific objectives may require organism acclimation to the dilution water when it is different from the holding/culture water.

6.2 Test Concentration Series

The polychaete species is exposed in replicate chambers to whole sediment samples and to a laboratory and/or reference sediment control.

6.3 Overlying Water

Overlying water for sediment tests is either GP-2 artificial seawater made with deionized water, dechlorinated tap water mixed with commercially available synthetic sea salts, or an appropriate receiving water. Batches of GP-2 at the appropriate salinity are made for the chronic testing using the formulation in US EPA (2002).

The source of the dechlorinated tap water is the City of Baltimore municipal water system. Upon entry to the laboratory, the water passes through a high-capacity, activated carbon filtration system to remove chlorine and possible organic contaminants. This water source has proven safe for aquatic organism toxicity testing at EA, as evidenced by maintenance of multigeneration *Hyalella azteca* and fathead minnow cultures with no evident loss of fecundity. The dechlorinated tap water or deionized tap water is mixed with commercially available synthetic sea salts to a salinity specified by the project study plan.

6.4 Test Vessels and Test Volume

For large polychaete species (e.g., *Nereis virens*), test chambers are typically 10-gallon aquaria which contain enough sediment to provide an even layer of approximately 3 to 5 cm on the bottom of each aquarium. Overlying water is added to each replicate to bring the total volume to 20 L.

Testing with a smaller polychaete species (e.g., *Neanthes arenaceodentata*) may be conducted in 1-L beakers with 175 ml of sediment and 700 ml of overlying water.

6.5 Test Organism Size and Number

Test organisms should be approximately equal in size and should provide enough tissue per replicate for the selected chemical analyses after the test exposure period. For *N. virens*, the bioaccumulation test is typically conducted with five replicates per test sediment and control sediment, with 20 to 30 organisms per replicate. Bioaccumulation testing with *N. arenaceodentata* generally utilizes five replicates of five organisms.

6.6 Test Environment

The test vessels are maintained in an environmentally controlled laboratory with a 16-hour light, 8-hour dark photoperiod. Temperature within the environmental room is monitored continuously using temperature recorders and is maintained at $20\pm 1^{\circ}\text{C}$ (unless a different project-specific temperature is required).

6.7 Test Procedures and Observations

Test organisms are randomly distributed into the test chambers seven days (US EPA and US Army COE 2015) after addition of the sediment and overlying water to the test vessels. Test organisms may be fed Tetramin flake food for the duration of the test; however, test chambers should be examined daily for the formation of fungus or the accumulation of excess food on the sediment surface. Food rations should be decreased in all replicates if the dissolved oxygen level in any replicate drops below 60 percent saturation. Organisms are observed daily during the test and any dead organisms are recorded and removed.

Depending on project-specific requirements, the overlying water may be renewed during the test. Renewals are accomplished by siphoning the overlying water from each tank to a level approximately 2 cm above the sediment surface. Fresh overlying water is then slowly introduced to each tank so as not to disturb the sediment surface. Alternatively, the test may be conducted under a continuous flow-through system if required by the project.

Samples of overlying water from the test sediment and control or reference sediment may be analyzed for conductivity, alkalinity, hardness, and total residual chlorine. Measurements of water quality are taken at test initiation and daily thereafter for dissolved oxygen, pH, temperature, and salinity from a minimum of one replicate of each test sediment and control sediment. Oxidation-reduction potential (ORP) will be monitored and recorded throughout the equilibration and the test duration (SOP L-45). Five test chambers will be prepared from each of five sampling stations to monitor ORP. Daily ORP measurements will be recorded. Analytical determinations are conducted according to APHA et al. (2012) and US EPA (1979). Overlying water may be gently aerated, if necessary, to maintain dissolved oxygen levels at or above 60 percent saturation.

Test duration may be 10 to 28 days depending on project requirements. The test duration may be extended at the request of the client. Test organisms are recovered from the test chambers and the number of live organisms in each replicate are recorded on the test data sheets. The test organisms are then transferred to clean saltwater holding tanks (one tank per replicate) and are held at least 24 hours to purge the digestive tracts. The organisms are not fed during the purge period and any organisms that die during this time are recorded and removed. Organisms are then removed from the holding tanks and processed accordingly for the chemical analyses.

6.8 Data Analysis

Statistical analyses can be performed on percent survival and on chemical concentrations analyzed in each sediment sample. An analysis of variance (ANOVA) and t-Test are used to analyze significance of effects between the control sediment and a single test sediment (US EPA 2002). Alternatively, Tukey's Test may be performed to check the difference between all pairs of treatments. Other appropriate statistical analyses may be performed. The statistical methods

used are specified in the final report.

7. FINAL REPORT

The final report is prepared to contain, at a minimum, the following information:

- Objectives and procedures stated in the approved protocol, including any changes made to the original protocol
- Identity of the test article(s) by name or code number and their strength (i.e., quality/purity), and a description of any pretreatment
- Source of the overlying water, its chemical characteristics, and a description of any pretreatment
- Test treatments used and duration of the assay
- Survival of organisms in each treatment
- Water quality characteristics (pH, dissolved oxygen, temperature, etc.) of overlying water from reference, control, and test sediment treatments
- Any unforeseen circumstances that may have affected the quality or integrity of the study
- Signature of the project manager, senior technical reviewer, and quality control officer authorizing release of the report
- Location of all archived data and the original copy of the final report at EA

Items of data to be included in the report consist of experimental design and test performance, effects on general appearance of test organisms (if applicable), morbidity and mortality, presentation of water quality characteristics, and appropriate statistical evaluations.

8. QUALITY ASSURANCE

8.1 Amendments to Protocol

Amendments to the authorized protocol established by EA or by the client are made only after proper authorization. Such authorization is achieved by completion of the Protocol Amendment Form by EA after consultation with the client.

8.2 Standard Operating Procedures

Unless otherwise specified, all procedures given in the protocol are subject to detailed Standard Operating Procedures (SOPs) which are contained in the SOP manuals of the participating departments. These SOPs and protocols generally follow the type of requirements in the US EPA's Good Laboratory Practice Standards (GLPs) (US EPA 1989).

8.3 Reference Toxicant

A reference toxicant test, utilizing potassium chloride, sodium dodecyl sulfate (SDS), copper sulfate, or another appropriate chemical is used as an internal quality check of the sensitivity of the test organisms. Testing is conducted on each population of organisms purchased for testing from an outside source if reference toxicant data are not available from the supplier on the acquired lot. The results of each test are compared with historical, species-specific toxicological information from reference toxicant tests performed at EA, to determine if the results are within acceptable limits. Limits are established using the control charts outlined in US EPA (2002).

8.4 Quality Assurance Evaluation

Studies conducted under this protocol may be subject to internal audit by EA's Quality Assurance Unit. A quality control officer is responsible for monitoring each study to assure the client that the facilities, equipment, personnel, methods, practices, records, and controls are in conformance with EA's QC program and, if applicable, US EPA's GLPs.

8.5 Inspection by Regulatory Authorities

In the event of an inspection of EA by an outside authority during the course of the study, the client whose study is being inspected will be consulted before examiners are permitted access to any of the project records or the experimental areas.

8.6 Corrective Action

Corrective action is initiated when a quality control measure is determined to be outside of a predetermined acceptance range. Corrective action may result from internal or external activities. Procedures for handling out-of-control data are detailed in Section 11 of the laboratory Quality Assurance and Standard Operating Procedures Manual.

8.7 Archives

Copies of project-specific records shall be transferred to the client promptly after the project is completed or as negotiated and budgeted. Original primary data are retained at EA for 5 years. Primary data include chain-of-custody records, laboratory data sheets, records, memoranda, notes, photographs, microfilm, and computer printouts that are a result of the original observations and activities of the study and which are necessary for the reconstruction and evaluation of the study report.

8.8 Location

Studies are conducted at the Ecotoxicology Laboratory of EA Engineering, Science, and Technology, Inc. in Hunt Valley, Maryland.

9. HEALTH AND SAFETY

9.1 Safety

All laboratory staff members are required to read EA’s laboratory safety manual (EA 2012 or most recent version) prior to working in the laboratory. The safety manual includes general safety rules to be followed in the laboratory, procedures for cleaning up spills and reporting accidents, the location and use of safety equipment, and the safe handling and storage of chemicals. A copy of the safety manual is located in the testing laboratory.

9.2 Pollution Prevention and Waste Management

Wastes generated by the laboratory during toxicity testing must be properly handled and disposed of in accordance with the laboratory safety manual and applicable local, state, and federal regulations. Procedures for water disposal is detailed in the laboratory Quality Assurance and Standard Operating Procedures Manual.

10.2 Test Specifications

Test Organism: A polychaete species (e.g., *Nereis virens* or *Neanthes arenaceodentata*), as specified by the project study plan

Temperature:	20±1°C
Light Quality:	Wide-spectrum fluorescent light
Light Intensity:	50-100 f.c.
Photoperiod:	16-hour light, 8-hour dark
Overlying Water:	Synthetic seawater or appropriate receiving water
Aeration:	Gentle aeration should be provided through a 1-ml glass pipet, placed no closer than 2 cm above the sediment surface
Test Container:	<i>N. virens</i> – 10 gallon aquaria <i>N. arenaceodentata</i> – 1 L beaker
Test Volume:	<i>N. virens</i> - Approximate 3-5 cm layer of sediment with overlying water to a total volume of 20 L <i>N. arenaceodentata</i> – 175 ml sediment and 700 ml overlying water
Number of Replicates:	5
Number of Organisms per Replicate:	<i>N. virens</i> – 20 to 30 <i>N. arenaceodentata</i> – 5
Feeding Regime:	Tetramin flake food at a rate of 1% wet organism weight
Test Duration:	10-28 days
Endpoints:	Survival and bioaccumulated concentrations of selected chemical parameters
Test Acceptability:	Sufficient biomass at end of test to conduct chemical analyses

No. L-38

Sediment Toxicity Test with *Leptocheirus plumulosus*

PROTOCOL LP-SED-03-T

**SEDIMENT TOXICITY TEST WITH *Leptocheirus plumulosus*
(EPA /600/R-94/025)**

1. TEST OBJECTIVE

To assess the toxicity of a whole sediment sample to estuarine amphipod *Leptocheirus plumulosus* and determine the effects on survival, reburial and/or growth of the test organisms compared to controls.

1.1 Detection Limits

Detection limits of the toxicity of a sediment or chemical are organism dependent.

1.2 Definitions

Refer to Appendix A of EA SOP Manual (EA 2013).

2. INTERFERENCES

Improperly cleaned glassware and sampling equipment can add toxicity to sediment. Improper sample collection, handling and storage also can affect the bioavailability of contaminants in sediment. Sediment grain size and texture may influence the response of test organisms. Test temperature and the addition of food, water or solvents to the test chambers may alter bioavailability of toxicants. Excess food can promote the growth of bacteria. The presence of indigenous organisms in the sediment may affect survival or growth of test organisms and confound test results. Other naturally occurring chemical characteristics such as ammonia and sulfide can modify organism response.

3. TEST EQUIPMENT

- 3.1 Environmental chamber capable of maintaining target test temperature, lighting and photoperiod.
- 3.2 Glassware (large diameter pipets, 1-L beakers)
- 3.3 Meters capable of measuring temperature, pH, dissolved oxygen and salinity
- 3.4 Oil free air supply to aerate overlying water.
- 3.5 Aeration equipment with glass pipets
- 3.6 Siphon bulb
- 3.7 Forceps
- 3.8 Sieve

4. CALIBRATION

Refer to Section 10 of EA SOP Manual (EA 2013).

5. TEST ARTICLE

5.1 Description/Identification

Unless otherwise specified, the test material is supplied by the client. The test article is a whole sediment sample. Adequate chemical specifications with special reference to hazardous properties and storage conditions are also supplied by the client. When available, information on the stability, composition, or other characteristics which define the test article are on the file with the client.

5.2 Methods of Synthesis

The test article is a sediment sample. Information on the method of synthesis, stability, composition, or other characteristics which define the test article are on file with the client.

5.3 Sample Preparation, Collection, Preservation, Shipment and Storage

Depending upon the project, the sediment may be screened through a suitably sized sieve to remove large particles and indigenous organisms, and then homogenized before being placed in the test chambers. Sediment and overlying water will be added to test vessels seven days prior to introduction of test organisms in order to allow suspended sediments to settle.

Sediment samples analyzed by this method have a recommended holding time of eight weeks from end time of collection to first use. Sediment samples are cooled to 4°C and shipped via overnight courier to ensure temperature less than 6°C at receipt. When not being used for testing sediment samples are stored in the dark at 4°C.

When EA personnel are responsible for sample collection, the sample collection procedures will follow guidelines specified in accordance with EPA guidelines (EPA-600-R-94-025).

6. EXPERIMENTAL DESIGN

6.1 Test Organisms

6.1.1 Species

The test species is the estuarine amphipod *Leptocheirus plumulosus*.

6.1.2 Source

L. plumulosus used for toxicity tests are obtained from EA's Culture Facility or from a scientific organism vendor as specified in the report.

6.1.3 Culturing and Holding Conditions

EA's Culture Facility maintains *L. plumulosus* cultures in clean control sediment with 20 ppt overlying laboratory water. Organism stocks are cultured and held in glass aquaria, and the amphipods are fed finely ground Tetramin flake food. The amphipods are maintained in an environmentally controlled laboratory at 20±2°C, with a 16-hour light/8-hour dark photoperiod cycle. Prior to use in toxicity testing, the organisms are gradually acclimated to testing conditions and to the overlying water used in testing, if appropriate. Certain regulatory or project specific objectives may require organism acclimation to the dilution water when it is different from the holding/culture water.

6.1.4 Size of Test Organisms at Test Initiation

Immature amphipods 2-4 mm in length are used for testing.

6.2 Test Concentration Series

L. plumulosus are exposed in replicate chambers to whole sediment samples and to a laboratory sediment and/or reference sediment.

6.3 Overlying Water

Overlying water for sediment tests is either an appropriate receiving water or synthetic seawater. Artificial seawater may be prepared by adding reagent-grade chemicals to deionized water (US EPA 2002) or by mixing commercially available synthetic sea salts to dechlorinated tap water.

The source of the dechlorinated tap water is the City of Baltimore municipal water system. Upon entry to the laboratory, the water passes through a high-capacity, activated carbon filtration system to remove chlorine and possible organic contaminants. This water source has proven safe for aquatic organism toxicity testing at EA, as evidenced by maintenance of multigeneration *Hyalella azteca* and fathead minnow cultures with no evident loss of fecundity. The dechlorinated tap water or deionized tap water is mixed with commercially available bioassay grade synthetic sea salts to a salinity of approximately 20±2 ppt or a salinity specified by the project study plan.

6.4 Test Vessels and Test Volume

Test vessels are 1-L exposure beakers containing 175 ml of sediment and 800 ml of overlying water. The size of the test vessels and the volume of sediment and overlying water may be changed depending on the study requirements.

6.5 Test Organism Number

Tests are conducted using at least four replicate chambers per sediment sample, with at least 20

organisms per replicate chamber. Organisms are transferred using a large diameter pipet and are randomly assigned to each replicate test container. More replicates may be added, if needed.

6.6 Test Environment

The test vessels are maintained in an environmentally controlled laboratory with a 24-hour light, 0-hour dark photoperiod. Temperature within the environmental room is monitored continuously using temperature recorders and is maintained at $25\pm 1^{\circ}\text{C}$ (unless a different project-specific temperature is required).

6.7 Test Observations

Sediment and overlying water is added to the test vessels seven days (US EPA and US Army COE 2015) prior to introduction of test organisms in order to allow suspended sediments to settle and to allow the sediments to stabilize.

Water quality measurements of the overlying water are taken at test initiation and daily thereafter for dissolved oxygen, pH, temperature, and salinity from a minimum of one replicate of each sediment, reference, and control treatment. Oxidation-reduction potential (ORP) will be monitored and recorded throughout the equilibration and the test duration (SOP L-45). Five test chambers will be prepared from each of five sampling stations to monitor ORP. Daily ORP measurements will be recorded. Analytical determinations are conducted according to APHA et al. (2012) and EPA (1979). Aeration of the overlying water, if required, is provided through 1-ml glass pipets placed no closer than 2 cm above the sediment surface.

The study terminates after ten days of exposure to the sediment sample. At test termination, test organisms are retrieved to record the number of surviving amphipods. To evaluate the ability to rebury after the 10-day exposure period, surviving organisms from each replicate may be placed into clean control sediment with overlying water. The number of organisms that rebury after 1 hour is recorded. At the end of the test period, a growth endpoint may be determined through length measurement and/or dry weight determination. Surviving organisms are preserved in 95 percent ethanol if lengths are to be measured. Length is measured using an ocular micrometer to measure body length from the base of the first antenna to the base of the third pleon segment along the dorsal surface. Length measurements are performed to 0.1 mm. Surviving amphipods may be placed in pre-weighed, oven-dried aluminum pans (one replicate per pan). Organisms are oven dried for a minimum of six hours at 100°C after which each pan is weighed. Mean dry weight of the amphipods (weight of pan and organisms minus weight of pan/number of organisms) is calculated.

6.8 Data Analysis

Statistical analyses are performed on percent survival, percent reburied, and/or mean dry weight data. The test results are analyzed using t-Tests to determine if any test sediment is statistically

different from the reference or laboratory sediment. Other statistical tests may be used as required by the project study plan. The statistical methods used are specified in the final report.

6.9 Test Acceptability

A test is considered acceptable if there is at least 90 percent survival in the control. An individual test may be conditionally acceptable if temperature, dissolved oxygen, and other specified conditions fall outside specifications, depending on the degree of the departure and the objectives of the tests.

7. FINAL REPORT

The final report is prepared to contain, at a minimum, the following information:

- Objectives and procedures stated in the approved protocol, including any changes made to the original protocol
- Identity of the test article(s) by name or code number and a description of any pretreatment
- Source of the overlying water, its chemical characteristics, and a description of any pretreatment
- Test concentration series used and duration of the assay
- Mean dry weights and/or lengths of test organisms with the respective standard deviations
- Water quality characteristics (pH, dissolved oxygen, temperature, salinity) of overlying water from reference, control and test sediment treatments
- Any unforeseen circumstances that may have affected the quality or integrity of the study
- Signature of the project manager, senior technical reviewer, and quality control officer authorizing release of the report
- Location of all archived data and the original copy of the final report at EA

Items of data to be included in the report consist of experimental design and test performance, effects on general appearance of test organisms (if applicable), morbidity and mortality, tabular presentation and appropriate statistical evaluation of water quality characteristics, survival, weight and/or length data.

8. QUALITY ASSURANCE

8.1 Amendments to Protocol

Amendments to the authorized protocol established by EA or by the client are made only after proper authorization. Such authorization is achieved by completion of the Protocol Amendment Form by EA after consultation with the client.

8.2 Standard Operating Procedures

Unless otherwise specified, all procedures given in the protocol are subject to detailed Standard Operating Procedures (SOPs) which are contained in the SOP manuals of the participating departments. These SOPs and protocols generally follow the type of requirements in the US EPA's Good Laboratory Practice Standards (GLPs) (US EPA 1989).

8.3 Reference Toxicant

A reference toxicant test, utilizing cadmium chloride or another appropriate chemical is used as an internal quality check of the sensitivity of the test organisms. Testing is conducted on each population of organisms purchased for testing from an outside source if reference toxicant data are not available from the supplier on the acquired lot. The results of each test are compared with historical, species-specific toxicological information from reference toxicant tests performed at EA, to determine if the results are within acceptable limits. Limits are established using the control charts outlined in US EPA (2002).

8.4 Quality Assurance Evaluation

Studies conducted under this protocol may be subject to internal audit by EA's Quality Assurance Unit. A quality control officer is responsible for monitoring each study to assure the client that the facilities, equipment, personnel, methods, practices, records, and controls are in conformance with EA's QC program and, if applicable, US EPA's GLPs.

8.5 Inspection by Regulatory Authorities

In the event of an inspection of EA by an outside authority during the course of the study, the client whose study is being inspected will be consulted before examiners are permitted access to any of the project records or the experimental areas.

8.6 Corrective Action

Corrective action is initiated when a quality control measure is determined to be outside of a predetermined acceptance range. Corrective action may result from internal or external activities. Procedures for handling out-of-control data are detailed in Section 11 of the

Laboratory Quality Assurance and Standard Operating Procedures Manual.

8.7 Archives

Copies of project-specific records shall be transferred to the client promptly after the project is completed or as negotiated and budgeted. Original primary data are retained at EA for 5 years. Primary data include chain-of-custody records, laboratory data sheets, records, memoranda, notes, photographs, microfilm, and computer printouts that are a result of the original observations and activities of the study and which are necessary for the reconstruction and evaluation of the study report.

8.8 Location

Studies are conducted at the Ecotoxicology Laboratory of EA Engineering, Science, and Technology, Inc. in Hunt Valley, Maryland.

9. HEALTH AND SAFETY

9.1 Safety

All laboratory staff members are required to read EA's laboratory safety manual (EA 2012 or most recent version) prior to working in the laboratory. The safety manual includes general safety rules to be followed in the laboratory, procedures for cleaning up spills and reporting accidents, the location and use of safety equipment, and the safe handling and storage of chemicals. A copy of the safety manual is located in the testing laboratory.

9.2 Pollution Prevention and Waste Management

Wastes generated by the laboratory during toxicity testing must be properly handled and disposed of in accordance with the laboratory safety manual and applicable local, state, and federal regulations. Procedures for water disposal are detailed in the Laboratory Quality Assurance and Standard Operating Procedures Manual.

10.2 Test Specifications

Test Organism:	<i>Leptocheirus plumulosus</i>
Test Type:	Static, non-renewal
Organism Age/Size:	Immature amphipods 2-4 mm in length
Temperature:	25±1°C
Light Quality:	Wide-spectrum fluorescent light
Light Intensity:	50-100 f.c.
Photoperiod:	24-hour light, 0-hour dark
Overlying Water:	Synthetic seawater or appropriate receiving water
Salinity:	20±2 ppt
Aeration:	Gentle aeration may be provided through a 1-ml glass pipet, placed no closer than 2 cm above the sediment surface
Test Container:	1-L beaker
Test Volume:	175 ml of sediment with 800 ml of overlying water
Number of Replicates:	Minimum of four
Number of Organisms per Replicate:	20
Feeding Regime:	None
Test Duration:	10 days
Endpoints:	Survival (reburial and/or growth is optional)
Test Acceptability:	≥90% survival in control sediment

No. L-39

Sediment 28-Day Toxicity Test with *Leptocheirus plumulosus*

PROTOCOL LP-CH-03-T

SEDIMENT 28-DAY TOXICITY TEST WITH *Leptocheirus plumulosus*

1. TEST OBJECTIVE

To assess the toxicity of a whole sediment sample to estuarine amphipod *Leptocheirus plumulosus* and determine the effects on survival, growth (determined by dry weight and/or length) and reproduction of the test organisms compared to controls.

2. INTERFERENCES

Improperly cleaned glassware and sampling equipment can add toxicity to sediment. Improper sample collection, handling and storage also can affect the bioavailability of contaminants in sediment. Sediment grain size and texture may influence the response of test organisms. Test temperature and the addition of food, water or solvents to the test chambers may alter bioavailability of toxicants. Excess food can promote the growth of bacteria. The presence of indigenous organisms in the sediment may affect survival or growth of test organisms and confound test results. Other naturally occurring chemical characteristics such as ammonia and sulfide can modify organism response.

3. TEST EQUIPMENT

- 3.1 Environmental chamber capable of maintaining target test temperature, lighting and photoperiod.
- 3.2 Glassware (graduated cylinders, 3-L pitchers, volumetric flasks, pipettes, beakers)
- 3.3 Meters capable of measuring temperature, pH, dissolved oxygen and salinity
- 3.4 Oil free air supply for supplying test solutions if needed or to aerate samples with supersaturated dissolved oxygen levels
- 3.5 Siphon bulb
- 3.6 Dissecting microscope
- 3.7 Pre-weighed aluminum weigh pans.
- 3.8 Forceps
- 3.9 Balance capable of weighing to 0.00001g.
- 3.10 Desiccator
- 3.11 Drying oven

4. CALIBRATION

Refer to Section 10 of EA SOP Manual (EA 2013).

5. TEST ARTICLE

5.1 Description/Identification

Unless otherwise specified, the test material is supplied by the client. The test article is a whole sediment sample. Adequate chemical specifications with special reference to hazardous properties and storage conditions are also supplied by the client. When available, information on the stability, composition, or other characteristics which define the test article are on the file with the client.

5.2 Sample Preparation

Depending upon the project, the sediment may be screened through a suitably sized sieve to remove large particles and indigenous organisms, and then homogenized before being placed in the test chambers. Sediment and overlying water will be added to test vessels seven days prior to introduction of test organisms in order to allow suspended sediments to settle.

5.3 Sample Collection, Preservation, Shipment and Storage

Depending upon the project, the sediment may be screened through a suitably sized sieve to remove large particles and indigenous organisms, and homogenized before being placed in the test chambers. Sediment and overlying water will be added to test vessels seven days prior to introduction of test organisms in order to allow suspended sediments to settle.

Sediment samples analyzed by this method have a recommended holding time of eight weeks from end time of collection to first use. Sediment samples are cooled to 4°C and shipped via overnight courier to ensure temperature less than 6°C at receipt. When not being used for testing sediment samples are stored in the dark at 4°C.

6. EXPERIMENTAL DESIGN

6.1 Test Organisms

6.1.1 Species

The test species is the estuarine amphipod *Leptocheirus plumulosus*.

6.1.2 Source

Leptocheirus plumulosus used for toxicity tests are obtained from in-house cultures, or from a scientific organism vendor as specified in the report.

6.1.3 Culturing and Holding Conditions

Stocks obtained from a scientific vendor are transferred into holding tanks with clean control sediment and overlying water. The *Leptocheirus plumulosus* are maintained in an environmentally controlled laboratory at 20±2°C with a 16-hour light/8-hour dark photoperiod cycle. During holding, the amphipods are fed finely ground Tetramin flake food. The organisms are gradually acclimated to testing conditions prior to use in testing. Certain regulatory or project specific objectives may require organism acclimation to the dilution water when it is different from the holding/culture water.

6.1.4 Size of Test Organisms at Test Initiation

Immature amphipods which pass through a 500 µm screen, but are retained on a 250 µm screen, are used to initiate toxicity tests.

6.2 Test Concentration Series

L. plumulosus are exposed in replicate chambers to whole sediment samples and to a laboratory or reference sediment control.

6.3 Overlying Water

Overlying water for sediment tests is either GP-2 artificial seawater made with deionized water, dechlorinated tap water mixed with commercially available synthetic sea salts, or an appropriate receiving water. Batches of GP-2 at the appropriate salinity are made for the chronic testing using the formulation in US EPA (2002).

The source of the dechlorinated tap water is the City of Baltimore municipal water system. Upon entry to the laboratory, the water passes through a high-capacity, activated carbon filtration system to remove chlorine and possible organic contaminants. This water source has proven safe for aquatic organism toxicity testing at EA, as evidenced by maintenance of multigeneration *Hyalella azteca* and fathead minnow cultures with no evident loss of fecundity. The dechlorinated tap water or deionized tap water is mixed with commercially available synthetic sea salts to a salinity of approximately 20±2 ppt or a salinity specified by the project study plan.

6.4 Test Vessels and Test Volume

Test vessels are 1-L exposure beakers containing 100-200 ml of sediment and 400-800 ml of overlying water (typically 1:4 ratio of sediment to overlying water). The size of the test vessels, and the volume of sediment and overlying water may be changed depending on the study requirements.

6.5 Test Organism Number

Tests are conducted using a minimum of four replicate chambers per sediment sample, with 20 organisms per replicate chamber.

6.6 Test Environment

The test vessels are maintained in an environmentally controlled laboratory with a 16-hour light, 8-hour dark photoperiod. Temperature within the environmental room is monitored continuously using temperature recorders and is maintained at $20\pm 1^{\circ}\text{C}$ (unless a different project-specific temperature is required).

Seven days (US EPA and US Army COE 2015) before test initiation, the sediment is loaded into the test chambers and overlying water is carefully added to each chamber. Aeration may be provided to each test replicate through a 1-ml glass pipet, placed no closer than 2 cm above the sediment surface. The test chambers are left undisturbed to allow any suspended sediment to settle prior to introducing the test organisms. The introduction of the test organisms to the test chambers 7 days later marks the initiation of the toxicity test.

6.7 Test Observations

The overlying water in the test chambers is replaced a minimum of three times a week (e.g., Monday, Wednesday, and Friday) for the 28-day test duration. Water quality measurements (temperature, pH, dissolved oxygen, and salinity) are recorded at test initiation, test termination, and prior to each renewal from a minimum of one replicate of each sediment, reference, and control treatment. Oxidation-reduction potential (ORP) will be monitored and recorded throughout the equilibration and the test duration (SOP L-45). Five test chambers will be prepared from each of five sampling stations to monitor ORP. Daily ORP measurements will be recorded. Renewal of the overlying water is performed three times per week. The overlying water may be gently aerated, if necessary, to maintain dissolved oxygen levels at ≥ 4.0 mg/L. Analytical determinations are conducted according to APHA et al. (2012) and EPA (1979).

The study terminates after 28 days of exposure to the sediment sample. Additionally, a subsection of the test chambers will be sacrificed at 10 days for a survival determination. The remaining test chambers will be continued until the 28 day test termination. At test termination, the sediment from each replicate is carefully sieved to retrieve all adult organisms and offspring. The number of surviving adults and offspring is recorded for each replicate. The reproductive response for the 28-day exposure test is the average number of offspring produced per surviving female. Surviving adults are then examined under a dissecting microscope to determine gender and in the case of females, the presence of eggs or embryos in the brood pouch.

At the end of the test period, a growth endpoint may be determined through length measurement and/or dry weight determination. For length measurements, surviving organisms are preserved in 70 percent ethanol, and body length from the base of the first antenna to the base of the third

pleon segment along the dorsal surface is measured using an ocular micrometer. Length measurements are performed to 0.1 mm. For dry weight determinations, surviving amphipods may be placed in pre-weighed, oven-dried aluminum pans (one replicate per pan). Organisms are dried in an oven for a minimum of six hours at 100°C after which each pan is weighed. Mean dry weight of the amphipods in each replicate is calculated by subtracting the weight of the pan from the combined weight of the pan and organisms, then dividing by the number of surviving organisms per replicate.

6.8 Data Analysis

Statistical analyses can be performed on percent survival, dry weight, and reproductive data. An analysis of variance (ANOVA) and t-Test are used to analyze significance of effects between the control sediment and a single test sediment (US EPA 2002). Alternatively, Tukey's Test may be performed to check the difference between all pairs of treatments. Other appropriate statistical analyses may be performed. The statistical methods used are specified in the final report.

6.9 Test Acceptability

A test is considered acceptable if there is at least 80 percent survival in the control. An individual test may be conditionally acceptable if temperature, dissolved oxygen, and other specified conditions fall outside specifications, depending on the degree of the departure and the objectives of the tests.

7. FINAL REPORT

The final report is prepared to contain, at a minimum, the following information:

- Objectives and procedures stated in the approved protocol, including any changes made to the original protocol
- Identity of the test article(s) by name or code number and a description of any pretreatment
- Source of the overlying water, its chemical characteristics, and a description of any pretreatment
- Test concentration series used and duration of the assay
- Mean dry weights and/or lengths of test organisms with the respective standard deviations
- Average number of offspring produced per surviving female with respective standard deviations

- Water quality characteristics (pH, dissolved oxygen, temperature, etc.) of overlying water from reference, control and test sediment treatments
- Any unforeseen circumstances that may have affected the quality or integrity of the study
- Signature of the project manager, senior technical reviewer, and quality control officer authorizing release of the report
- Location of all archived data and the original copy of the final report at EA

Items of data to be included in the report consist of experimental design and test performance, effects on general appearance of test organisms (if applicable), morbidity and mortality, tabular presentation and appropriate statistical evaluation of water quality characteristics, survival, weight and/or length data, and/or reproductive data.

8. QUALITY ASSURANCE

8.1 Amendments to Protocol

Amendments to the authorized protocol established by EA or by the client are made only after proper authorization. Such authorization is achieved by completion of the Protocol Amendment Form by EA after consultation with the client.

8.2 Standard Operating Procedures

Unless otherwise specified, all procedures given in the protocol are subject to detailed Standard Operating Procedures (SOPs) which are contained in the SOP manuals of the participating departments. These SOPs and protocols generally follow the type of requirements in the US EPA's Good Laboratory Practice Standards (GLPs) (US EPA 1989).

8.3 Reference Toxicant

A reference toxicant test, utilizing sodium dodecyl sulfate (SDS), cadmium chloride, or another appropriate chemical is used as an internal quality check of the sensitivity of the test organisms. Testing is conducted on each population of organisms purchased for testing from an outside source if reference toxicant data are not available from the supplier on the acquired lot. The results of each test are compared with historical, species-specific toxicological information from reference toxicant tests performed at EA, to determine if the results are within acceptable limits. Limits are established using the control charts outlined in US EPA (2002).

8.4 Quality Assurance Evaluation

Studies conducted under this protocol may be subject to internal audit by EA's Quality Assurance Unit. A quality control officer is responsible for monitoring each study to assure the client that the facilities, equipment, personnel, methods, practices, records, and controls are in conformance with EA's QC program and, if applicable, US EPA's GLPs.

8.5 Inspection by Regulatory Authorities

In the event of an inspection of EA by an outside authority during the course of the study, the client whose study is being inspected will be consulted before examiners are permitted access to any of the project records or the experimental areas.

8.6 Corrective Action

Corrective action is initiated when a quality control measure is determined to be outside of a predetermined acceptance range. Corrective action may result from internal or external activities. Procedures for handling out-of-control data are detailed in Section 11 of the Laboratory Quality Assurance and Standard Operating Procedures Manual.

8.7 Archives

Copies of project-specific records shall be transferred to the client promptly after the project is completed or as negotiated and budgeted. Original primary data are retained at EA for 5 years. Primary data include chain-of-custody records, laboratory data sheets, records, memoranda, notes, photographs, microfilm, and computer printouts that are a result of the original observations and activities of the study and which are necessary for the reconstruction and evaluation of the study report.

8.8 Location

Studies are conducted at the Ecotoxicology Laboratory of EA Engineering, Science, and Technology, Inc. in Hunt Valley, Maryland.

9. HEALTH AND SAFETY

9.1 Safety

All laboratory staff members are required to read EA's laboratory safety manual (EA 2012 or most recent version) prior to working in the laboratory. The safety manual includes general safety rules to be followed in the laboratory, procedures for cleaning up spills and reporting accidents, the location and use of safety equipment, and the safe handling and storage of chemicals. A copy of the safety manual is located in the testing laboratory.

9.2 Pollution Prevention and Waste Management

Wastes generated by the laboratory during toxicity testing must be properly handled and disposed of in accordance with the laboratory safety manual and applicable local, state, and federal regulations. Procedures for water disposal is detailed in the laboratory Quality Assurance and Standard Operating Procedures Manual.

10.2 Test Specifications

Test Organism:	<i>Leptocheirus plumulosus</i>
Organism Age/Size:	Immature amphipods which pass through a 500 µm screen but are retained on a 250 µm screen
Aeration:	Gentle aeration may be provided through a 1-ml glass pipet, placed no closer than 2 cm above the sediment surface
Temperature:	20±1°C
Light Quality:	Wide-spectrum fluorescent light
Light Intensity:	50-100 f.c.
Photoperiod:	16-hour light, 8-hour dark
Overlying Water:	Synthetic seawater or appropriate receiving water
Test Container:	1-L beakers
Test Volume:	100-200 ml of sediment with 400-800 ml of overlying water (typically 1:4 ratio of sediment to overlying water)

Number of Replicates:	minimum of 4 (Typically 8, 4 terminated at 10 days and 4 terminated at 28 days)
Number of Organisms per Replicate:	20
Feeding regime:	Finely ground Tetramin flake food, three times per week, after renewal of overlying water
Renewal of Overlying Water:	3 times/week (e.g., Monday, Wednesday, and Friday)
Test Duration:	28 days
Endpoints:	Survival, growth, and reproduction
Test Acceptability:	≥80 percent control survival

No. L-40

**Standard Operation Procedure for the Measurement of Hydrophobic
Organic Constituents in Sediment Porewater by Passive Sampling**

**Standard Operation Procedure for the Measurement of Hydrophobic Organic
Constituents in Sediment Porewater by Passive Sampling**

Prepared by

Upal Ghosh

University of Maryland Baltimore County

August 26, 2015

INTRODUCTION

This standard operating procedure (SOP) is for the measurement of hydrophobic organic compounds in sediment porewater based on ex-situ laboratory measurements. Passive sampling of the porewater phase has emerged as an alternative technique to assess freely dissolved concentrations of hydrophobic chemicals without interference from colloidal particles. Common passive sampling polymers that have been used include polyethylene (PE) and polyoxymethylene (POM). In this SOP, a recently published guidance document on passive sampling (Ghosh et al. 2014) is followed to measure equilibrium porewater concentrations for the selected hydrophobic organic compounds in sediments.

Briefly, the method involves equilibrating a slurry of the sediment in site water with passive samplers in a closed bottle for a period of 1 month with tumbling to ensure well-mixed equilibrium conditions. Before contacting with the sediment slurry, the passive sampler will be cleaned, and impregnated with selected performance reference compounds that allow assessment of the extent of equilibrium achieved during the contact period. After the period of contact, the passive sampler will be retrieved from the sediment slurry, cleaned to remove any attached sediment particles, and extracted in hexane and acetone to measure PCBs, PAHs, and other hydrophobic compounds sorbed into the passive sampler.

This SOP may change depending on equipment limitations or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s Facility Coordinator and the U.S. Environmental Protection Agency's (USEPA's) Remedial Project Manager. The ultimate procedure employed will be documented in the laboratory notebook.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use. Overall, the process involves 6 steps and these are described in detail below:

- 1) Preparation of the passive samplers including cleaning
- 2) Introduction of performance reference compounds
- 3) Contact of the passive sampler with a sediment slurry for 1 month
- 4) Removal of the passive sampler, cleaning, extraction, analysis
- 5) Interpretation of the analysis and calculation of equilibrium porewater concentrations
- 6) Quality assurance and quality control

1. PREPARATION OF PASSIVE SAMPLERS

This SOP is for the use of PE or POM based passive samplers:

1.1. Selection and Pre-cleaning

The recommended source of POM is the commercially available 77 µm sheets available from CS Hyde and Company (Lake Villa, Illinois, USA). POM sheets need to be cut into appropriately sized pieces, typically 2.5 cm wide strips, 2.5 to 15.2 cm long.

Low density PE is purchased from hardware/painting stores in large sheets ('dropcloth or plastic tarp' material; Figure 4-1) with thickness of 25 µm (1 mil). The sheet is cut into strips sized for the environment and frames/meshes to be used.

The POM or PE strips will be pre-cleaned to remove residual monomers and any target and non-target contaminants. The pre-cleaning involves triplicate batch extractions (24 hours each) with hexane/acetone (50:50) as described in Jonker and Koelmans, 2001. After cleaning, the passive sampling strips are kept in a clean glass bottle at -4 °C in the dark to prevent recontamination from exposure to laboratory air and other sources.

All laboratory glassware that will come in contact with sediment samples, passive samplers, or extracts (e.g. vials, bottles, pipettes) will be cleaned following standard laboratory practice of trace organic analysis. This would involve cleaning of all glassware with Alconox® (or other low-phosphate detergent), followed by rinsing with water and methanol. After cleaning, all glassware will be air dried and baked in an oven overnight at 450 °C.

1.2. Selection of Polymer:Sediment Ratio

While, using a large mass of polymer has the advantage of greater mass of analyte adsorbed leading to improved detection limits, the accurate measurement of porewater concentration requires that negligible depletion of the matrix or porewater concentration (described as < 1% depletion) occurs when equilibrium is reached. For target chemicals, the introduction of a passive sampler will inevitably start depleting the mass of chemicals in the porewater, but desorption of the contaminant from the sediment will replenish the aqueous pool. To avoid depletive extractions, the sediment organic carbon-to-sampler ratio should be sufficiently large, as these are the two primary absorptive pools that compete for sorption of the hydrophobic contaminants in a sediment system. As a general rule (assuming sediment organic carbon and polymer matrices have similar partitioning characteristics), a ratio of 1:100 polymer mass to sediment organic carbon mass should reduce any depletion to an acceptable value of < 1%.

If more accurate estimate of chemical-specific K_{OC} and K_{PS} values are available, the 1:100 ratio can be refined as:

$$\frac{(M_{PS} * K_{PS})}{(M_{OC} * K_{OC})} = \left(\frac{1}{100} \right) \quad [1-1]$$

where, M_{PS} is the mass of the passive sampler, and M_{OC} is the mass of sediment organic carbon. Equation 1-1 can be reworked to solve for the mass of the passive sampler (M_{PS}):

$$M_{PS} = 0.001 * M_{OC} * \frac{K_{OC}}{K_{PS}} \quad [1-2]$$

If detection limits and other logistical considerations such as lack of prior accurate estimates of K_{OC} or M_{OC} do not maintain the depletion at <1%, it is possible to correct for the potential depletion as described in Fagervold et al. (2010). Such corrections are feasible when the depletion is still small (<10%) and within the range for which a linear relationship for partitioning characteristics of the sediment organic matter can be assumed. Also, when the goal of the porewater measurements is to assess site-specific native partition constants (e.g., K_{OC}), the decreased matrix concentrations (i.e., post-deployment sediment concentrations) can be measured and accounted for in the partitioning calculation.

1.3. Selection of Sediment Mass to be used for Equilibrium Experiments

Key criteria that are involved in deciding how much sediment mass should be used include concentration of the target analyte in the sediment and analytical detection limit. One approach for performing the calculation is to work backwards from the analytical mass detection limits. For example, if the analytical detection limit is X ng/mL for a given target contaminant in the final solvent extract, and the desire is to stay 10 times above the detection limit, one can target a final concentration of 10X ng/mL as the minimum. Assuming a final extract volume of 1 mL, this amounts to a mass of 10X ng analyte sampled in the polymer. The batch equilibrium experiments are designed such that not more than 1% of the analyte is transferred from the sediment into the passive sampler as described above. Thus, the minimum sediment mass that is required should have 1000X ng of the analyte. So, the mass of sediment required will equal $1000X/C_{sed}$ g; where, C_{sed} [ng/g] is the concentration of the analyte in sediment. For most applications, this ends up in the range of a minimum of 100-1000g sediment (wet) per replicate measurement. The sediment sample should be homogenized before placement into equilibrium bottles.

1.4. Exposure Time and Conditions

A typical exposure time used for well mixed batch experiments with POM or PE is 1 month. Results reported by Hawthorne et al. (2009) and Arp et al. (2015) indicate adequate equilibration even for octachlorobiphenyls in that period of time in well mixed batch systems. While sediment samples with high water content can be used directly to form a slurry, additional water may need to be added to form a freely flowing slurry for most sediments. Typical water content in a well formed slurry is 80% water. Site water, when available, can be used to supplement the water content for marine or estuarine sediments. If necessary, appropriate salinity water can be prepared by adding Instant Ocean salt mixture (or similar) as performed in Gomez Eyles et al. (2013). Exposure bottles should be well mixed, typically on a shaker table or on a bottle roller. The purpose of the mixing is to reduce the aqueous boundary layer thickness around the sediment particles and the passive sampler to enhance target contaminant mass transfer.

1.5. Use of Biocides to Inhibit Contaminant Biodegradation

For degradable compounds (e.g., low molecular weight PAHs), biocides such as sodium azide (100-1000mg/L; Cornelissen et al., 2006; Khalil et al., 2006; Zimmerman et al., 2004) is required to inhibit biological activity during the performance of the experiments. In addition, the experiments should be conducted in the dark or in amber bottles to reduce the chance of photodegradation of some target contaminants.

2. Impregnation of passive samplers with Performance Reference Compounds (PRCs)

2.1. Scope and application

This SOP describes the method of PRC impregnation in passive samplers. The SOP is suitable for impregnation of PE passive samplers. PRC impregnation and correction will not be performed for POM as the currently available correlation for dioxins/furans in POM did not use PRC correction.

Deployment time of PE inside the PRC mixture depends on the thickness of the passive sampler. The suggested deployment time in this SOP is suitable for PE sheets with thicknesses of 25µm.

2.2. Method description: Preparing PRC mixture in methanol/water (80/20 v/v)

Clean passive samplers are impregnated in a mixture of methanol/water by volume (80/20 v/v) spiked with PRCs. The system is left on a shaker until equilibrium is reached between the mixture and passive samplers. After impregnation, the samplers are soaked in 1L of DI water overnight to remove the methanol.

2.2.1 Calculate mass of PRC that should be injected to the mixture by the following equation (Booij et al., 2002):

$$N_t = N_m \frac{V_s + n * m_m * K_{ms}}{m_m * K_{ms}}$$

Where N_t is mass of PRC that needs to be added to the system (µg), N_m is the target amount of PRC per sampler (µg), V_s is volume of incubation solution (mL), n is number of samplers in solution, m_m is mass of each sampler (g), and K_{ms} is the membrane-solution partition coefficient (mL/g)

2.2.2. Add methanol with the volume of $0.8V_s$ to a wide mouth jar.

2.2.3. Add PRC with the mass of N_t (calculated in step 2.2.1) to methanol by spiking appropriate volume of PRC stock solution into the mixture.

2.2.4. Add DI water with the volume of $0.2V_s$ to the jar and stir the solution

2.3. Choice of PRC compounds:

The choice is based on the need to have PRCs covering a wide range of K_{ow} values, PRCs that do not interfere with the analysis of the target compounds, and compounds that are not already used as analytical internal standards or surrogates. Four deuterated PAHs and four ^{13}C labeled PCBs were chosen as PRCs for this study.

PAH PRCs:

Fluorine-D10

Pyrene-D10

Benz(a)anthracene-D12

Dibenz(a,h)anthracene-D14

PCB-PRCs:

PCB11 - 3,3'-Dichloro[$^{13}C_{12}$]biphenyl

PCB79 - 3,3',4,4'-Tetrachloro[$^{13}C_{12}$]biphenyl

PCB153 - 2,2',4,4',5,5'-Hexachloro[$^{13}C_{12}$]biphenyl

PCB159 - 2,3,3',4',5,5'-Hexachloro[$^{13}C_{12}$]biphenyl

2.4. Preparing passive samplers

- 2.4.1. Take out the PE passive samplers from hexane-acetone solution, let them dry under the hood, and soak them into the PRC methanol/water solution
- 2.4.2. Place the mixture on an orbital shaker for at least one week for PE impregnation.
- 2.4.3. Take out the strips from PRC solution and rinse them with DI water
- 2.4.4. Transfer samplers to a clean jar and add DI water until water surface is right above the samplers. Adding too much water will result in losing PRCs from the samplers.
- 2.4.5. Take out the strips from water solution and rinse them with DI water.
- 2.4.6. Use the PRC-loaded passive samplers immediately or leave them in the DI water in a refrigerator until use.

3. CONTACT OF THE PASSIVE SAMPLER WITH A SEDIMENT SLURRY FOR 1 MONTH

This SOP describes the setup of laboratory equilibrium studies using PE or POM passive samplers in mixed slurries.

3.1. Label wide mouthed amber-colored 1L bottles received from the field on the side as well as on the top of the cap. Make sure the labels are positioned such that they are not rubbed off after 1 month of rolling.

3.2. Prepare slurry water by dissolving 100 mg NaN_3 per L of site water. Use an ultraclean bottle with a volume of 5 L. Weigh 400 mg NaN_3 (e.g., on a piece of aluminum foil) and add to the bottle containing 4.0 L of site water. Shake firmly to dissolve and homogenize.

3.3. Transfer 100 ml of slurry water prepared in 3.2 into the 1L bottle, wipe the mouth of the bottle, and close the cap.

3.4. Once all bottles are filled with sediment and water, the passive samplers can be introduced in the bottles.

3.5. Weigh the first polymer strip. Record the exact weight in mg (two decimals, e.g., 50.92 mg) and add to the corresponding bottle. Close the cap tightly.

3.6. After passive samplers are placed in each bottle, place the bottles on a bottle roller set at 10 rpm in room temperature.

3.7. Roll the bottles for exactly 1 month. Frequently check the roller/bottles/labels.

3.8. Record room temperature daily.

4. REMOVAL OF THE PASSIVE SAMPLER, CLEANING, EXTRACTION, ANALYSIS

The method described here is for the extraction and measurement of hydrophobic organic compounds such as PCBs, PAHs, and pesticides such as DDT. The method is suitable for POM and PE passive samplers.

4.1. At the end of the contact period, retrieve the POM/PE passive samplers from the slurry bottles using a clean pair of tweezers. Clean the passive samplers with DI water, wipe the surface with Kim wipes (or similar) to make sure there is no sediment or solid residue attached to the samplers.

4.2. Use clean, labeled, 40-mL glass vials, one for each POM/PE strip. Tightly cap the vials using caps lined with Teflon. Label, and place in an ice-cooled cooler for shipping to the analytical laboratory under appropriate sample chain of custody.

- 4.3. Extraction of the passive samplers will be carried out at the analytical laboratory following the steps outlined here.
- 4.4. Add 25 mL of acetone/hexane (1:1 by vol.) to each vial. Use pesticide residue grade solvents.
- 4.5. Add an appropriate volume of the surrogate solution to each 40-mL vial. The surrogate compounds are based on the specific analytical method being used.
- 4.6. Place the extraction vials on an orbital shaker running at 30 rpm. Cover to prevent photodegradation of light sensitive contaminants. Note the time. After extraction overnight, remove the vials from the shaker.
- 4.7. Prepare clean, labeled 100-mL glass vials, one for each POM/PE strip. From each of the 40-mL extraction vials, transfer the solvent extract, but not the POM/PE strip, to its corresponding 100-mL vial. Cap, wrap, and freeze the 100-mL vials.
- 4.8. Add 25 mL of fresh acetone/hexane (1:1 by vol.) to each of the 40-mL extraction vials still containing the POM/PE strips. Cap, wrap, cover to prevent photodegradation and place on the shaker overnight.
- 4.9. After the extraction, transfer the liquid extract of each strip to the corresponding 100-mL vial containing the first day's extract (i.e., combine the first and second extracts of each strip). Cap, wrap, and freeze the 100-mL vials.
- 4.10. Perform the third and final extraction by repeating steps 4.8 and 4.9, above.
- 4.11. Allow the extracted POM/PE strips to air dry and record their weights using an analytical balance. This result is used to calculate the final target contaminant concentrations measured on the POM sampler in units of contaminant mass per POM/PE mass (e.g., ng/g POM).
- 4.12. Evaporate the final extracts in the 100-mL vials to 2 mL and proceed with sample clean-up (if necessary) and instrumental analysis for selected analytes.
- 4.13. Store the solvent extracts at -4°C in the dark until ready for instrumental analysis.

5. INTERPRETATION OF THE ANALYSIS AND CALCULATION OF EQUILIBRIUM POREWATER CONCENTRATIONS.

If the PRC loss for the range of compounds used is greater than 80%, no PRC correction is required and the aqueous concentration can be calculated based on the polymer-water partition constant:

$$C_{free} = C_{PS}/K_{PS-free}$$

Equation 1

For compound classes where the PRC loss is less than 80% a correction will be performed to calculate the equilibrium aqueous concentration based on the approach described below.

SOP for PRC correction

This SOP is based on the method developed by Fernandez et al., 2009. In order to use the method, the loss of at least three PRCs with different molar volumes must be measured during the deployment time of the passive samplers.

Parameters

t: deployment time (s)

T: dimensionless time of deployment

l: half polymer thickness (cm)

$C_{P,t}$: concentration of target compound in polymer at time t ($\mu\text{g}/\text{cm}^3$)

C_w : porewater concentration of target compound ($\mu\text{g}/\text{cm}^3$)

D_P : diffusivity in polymer (cm^2/s)

D_{SED} : diffusivity within the porous sedimentary medium (cm^2/s)

D_w : diffusivity in water (cm^2/s)

K_d : sediment-water partition coefficient (cm^3 water/ cm^3 sediment)

M_{target} : mass of target compound in polymer (μg)

$M_{PRC,int}$: initial mass of PRC in polymer (μg)

$M_{PRC,t}$: mass of PRC at time t in polymer (μg)

M_{inf} : equilibrium mass of target compound in polymer (μg)

n: porosity

τ : tortuosity ($= 1 - \ln n$)

K_{pw} : polymer-water partitioning coefficient (cm^3 water/ cm^3 polymer)

r_{sw} : volume ratio of whole sediment to water ($= 1/n$)

ϕ : ratio of diffusion coefficients

K_{PSED} : polymer-sediment partitioning coefficient (cm^3 sediment/ cm^3 polymer)

$$\phi = \frac{D_{SED}}{D_P} = \frac{D_w}{(1+r_{sw}K_d)\tau D_P} \cong \frac{D_w}{r_{sw}K_d\tau D_P} \quad (\text{Equation 2})$$

$$K_{PSED} = \frac{K_{pw}}{K_d} \quad (\text{Equation 3})$$

$$T = \frac{tD_{PE}}{l^2} \quad (\text{Equation 4})$$

5.1. For each PRC compound calculate $\frac{M_{PRC,t}}{M_{PRC,int}}$ and T (dimensionless time of deployment) using measured PRC loss

5.2. Use the plots provided by Fernandez et al., 2009 (available in supporting information) to find the intersection of $\frac{M_{PRC,t}}{M_{PRC,int}}$ and T for each PRC

- 5.3. Find the k_d value for all PRCs using the intersections
- 5.4. Determine the correlation between K_d and K_{ow} of PRCs
- 5.5. Estimate K_d value for any target chemical using the correlation obtained in step 4
- 5.6. Calculate ϕ and K_{PSED} using equations 2 and 3 and K_d values from step 5
- 5.7. Read $\frac{M_{target,t}}{M_{target,inf}}$ from the plots provided Fernandez et al., 2009 (available in supporting information).
- 5.8. Calculate C_w as: $C_w = \left(\frac{C_{P,t} \times M_{target,inf}}{K_{pw} \times M_{target,t}} \right)$

Source of polymer partition constants (K_{PE} and K_{POM})

The following literature sources will be used for PE partition constants:

For PCBs and parent PAHs: Correlation provided in Ghosh et al. (2014)

For alkylated PAHs: Correlation provided in Choi et al. (2015)

For DDT and other pesticides: Correlation provided in Fernandez et al. (2014)

For all other hydrophobic organic compounds, a $K_{PE}:K_{OW}$ correlation based on data provided for pesticides and PCBs in Fernandez et al (2014) will be used.

The following literature source will be used for POM partition constants:

For dioxins and Furans: Cornelissen et al. (2008)

6. QUALITY ASSURANCE AND QUALITY CONTROL

6.1. Polymer-specific Field Blanks (i.e., lab blanks)

Since the polymers used for passive sampling have high partition coefficients for hydrophobic organics, there is a significant chance of contamination of the polymers from exposure to the laboratory or field atmosphere. Passive samplers used for measurement should be protected from the laboratory and field environment through adequate containment and storage in clean glass jars (i.e., solvent washed and oven dried). Such contamination problems are especially important when measurements are being performed at low concentrations and the types of target contaminants being measured are ubiquitous in the environment such as low molecular weight PAHs. Thus every passive sampling investigation should include an adequate set of laboratory blanks. The laboratory performing the passive sampling measurements should demonstrate absence of contamination of laboratory blanks at the practical quantitation limits. In addition,

the laboratory should demonstrate that no significant loss of loaded PRCs occurred before sampler deployment in the sediment bottles.

Laboratory blanks should have no significant peaks where PRCs, surrogate standards, injection standards, and target analytes occur (<0.1 ng /g PE).

6.2. All pertinent field information and chains of custody will be provided to the sample processing team. Designated laboratory personnel will review the sample information and confirm that the number of individuals, collection date(s), collection time(s), species, and porewater analyses match the chains of custody. If any questions arise, laboratory personnel will contact the Project Manager and Laboratory Project Manager to resolve.

6.3. The laboratory logbook will be checked between steps to verify required information is completed per the next section.

6.4. A duplicate sample will be collected for every 20 samples collected and analyzed.

6.5. Blank sample extracts of clean PE and POM samplers will be prepared in the laboratory and sent for analysis of background levels of target analytes. The blank sample will be exposed to clean deionized water in closed bottles for the duration of the laboratory experiments to check for any exposure to laboratory contaminants.

**Standard Operation Procedure for the Measurement of Inorganic
Constituents in Sediment Porewater by Passive Sampling**

**Standard Operation Procedure for the Measurement of Inorganic
Constituents in Sediment Porewater by Passive Sampling**

Prepared by

University of Maryland Baltimore County

August 26, 2015

INTRODUCTION

The purpose of this document is to define the standard operating procedure (SOP) for analyzing porewater chemistry in sediments from the Newark Bay Study Area (NBSA). The dissolved inorganic constituents in sediment porewater will be measured using emerging and established techniques deemed appropriate within the project constraints. This SOP outlines the laboratory experimental setup and porewater measurement techniques chosen for the inorganic compounds of interest.

Generally, passive diffusion samplers consisting of dialysis bags will be used to characterize concentrations of inorganic compounds in representative sediment samples from the NBSA. The dialysis samplers will be constructed as described in Vroblesky and Pravecek 2002 and ITRC 2007. The dialysis bags, after cleaning, will be filled with deionized water adjusted to site salinity with Instant Ocean™ (or similar) aquarium sea salt mixture. The water will be purged with nitrogen to remove oxygen before filling into the dialysis bags. Multiple dialysis devices will be placed within the top 12 inches of sediment to allow the final collection of 1.5 liters of dialyzed porewater. The dialysis samplers will be allowed to equilibrate in the sediments for a period of 2 weeks. After removal, the water sample within the dialysis samplers will be emptied into clean bottles without headspace and preserved for shipping to the analytical laboratory.

This SOP may change depending on equipment limitations or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s Facility Coordinator and the U.S. Environmental Protection Agency's (USEPA's) Remedial Project Manager. The ultimate procedure employed will be documented in the laboratory notebook.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use. Overall, the process involves the following steps described in detail below:

- 1) Equipment decontamination procedures
- 2) Sediment preparation
- 3) Passive sampler preparation
- 4) Contact of the passive sampler with slurry for two weeks
- 5) Passive sampler removal, cleaning, extraction and analysis
- 6) Quality assurance and quality control

1. EQUIPMENT DECONTAMINATION PROCEDURES

This SOP describes the procedures to be used to decontaminate sampling equipment that will come into contact with sediment porewater for chemical analysis (e.g., bucket, dialysis sampler). Decontamination of sampling equipment will occur prior to initial use.

Equipment Decontamination

- 1.1. Personnel will wear suitable protective equipment to reduce exposure to chemicals and contaminants per laboratory health and safety SOPs.
- 1.2. All passive sampler manipulations will be performed while wearing suitable clean nitrile gloves that have been rinsed with high purity water. Gloves will be re-rinsed whenever any potentially unclean surface has been contacted.
- 1.3. Equipment will be placed in a wash tub or bucket containing Alconox® (or other low-phosphate detergent) in tap water, and scrubbed with a bristle brush or similar utensil. Equipment will be rinsed with tap water in a second wash tub or bucket, followed by a nitric acid rinse, a deionized “analyte-free” water rinse, a methanol rinse followed by a deionized water rinse. Rinses will utilize sufficient amounts of solvent/water to flush rather than just wet the surface. The volume of deionized water used during the rinse must be at least five times the volume of solvent used.
- 1.4. Following decontamination, equipment will be left to dry in a 105 °C oven overnight.
- 1.5. Used decontamination water and solvents will be collected and disposed in accordance with the laboratory’s established protocols.

2. SEDIMENT PREPARATION

This section describes the procedures for handling and preparing the sediment samples to be used for the porewater measurement and analysis.

All porewater measurements will be conducted in the laboratory through passive sampling techniques. The passive diffusion sample volume should be small relative to the volume of surrounding sediment as to minimize disturbance to the sediment/porewater equilibrium and the depletion of dissolved metals in the surrounding water.

From each sampling location, a 4-gallon sample of sediment will be collected, homogenized, and placed in a 5-gallon bucket. The remaining space in the bucket will be filled with site water. Sealed buckets will be transported to the Environmental Engineering laboratories at the University of Maryland, Baltimore County (UMBC).

For the metals and other ionizable species in porewater (i.e., inorganics), ex-situ laboratory equilibrium studies will be conducted in the laboratory in the 5-gallon buckets. Because the sediments will be disturbed at the time of collection, the buckets will be allowed to reconsolidate in the laboratory for 2 weeks to allow the sediments in each bucket to redevelop a natural oxidation reduction profile. For metals and other ionized species in porewater, the sampling method will involve the use of dialysis bags

containing clean water with matching site salinity. A schematic of the proposed laboratory exposure system is illustrated in Figure 1.

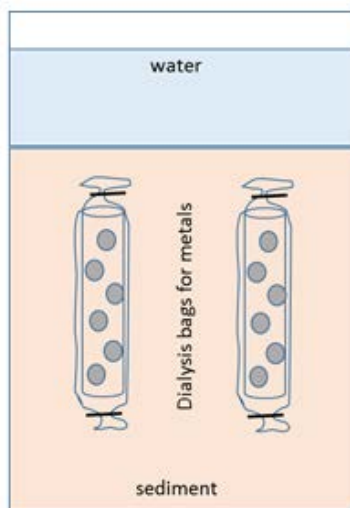

Figure 1. Illustration of proposed laboratory equilibrium experimental setup for porewater measurements. Dialysis bag devices for metals and ionizable species placed in static sediments in 5-gallon buckets.

3. PASSIVE SAMPLER PREPARATION

This section describes the procedures for preparing the passive samplers for the porewater measurement and analysis.

Preparing the passive samplers

3.1. As illustrated in Figure 1, the passive samplers for inorganics will consist of regenerated cellulose dialysis bags wrapped around perforated PVC plastic tubes or stiff mesh tubes (2" OD). To protect the dialysis membrane, the entire device will be covered with a flexible plastic netting (ITRC 2007).

3.2. Drill 1" diameter holes in the plastic pipe, such that fluid can flow freely throughout the dialysis bag and the plastic pipe; the purpose of the pipe is to provide a rigid structure to support the dialysis bag. Alternatively, rigid polypropylene mesh tubes such as available from Industrial Netting (www.industrialnetting.com) can be used. The open area in the tube or stiff mesh should be 50% of available surface.

3.3. Sand the drilled plastic pipe or mesh tube to remove burrs that could tear the membrane during construction or sampler deployment.

- 3.4. Clean the plastic pipe and low-density polyethylene mesh sleeve with deionized water to remove potential contaminants.
- 3.5. Cut the membrane tube (regenerated cellulose from Membrane Filtration Products Inc. (<http://www.membrane-mfpi.com/>)) approximately 1 to 1.5 feet longer than the plastic pipe. Tie a knot in one end of the membrane tube. The membrane should be pre-cleaned, hydrated and of size that fits around the 2" OD plastic tube or mesh.
- 3.6. Insert cleaned plastic pipe into membrane tube.
- 3.6 Prepare anaerobic deionized water by bubbling nitrogen through approximately 5 gallons of deionized water until the dissolved oxygen concentration is less than 0.5 milligrams per liter.
- 3.7 Add Sea Salt mixture (to match site salinity conditions) while still bubbling nitrogen and allow the contents to mix in the container. Close the container and make sure the salt is completely dissolved in the water.
- 3.8 Fill the sampler with saline anaerobic deionized water using a peristaltic pump.
- 3.9 Tie a knot at the top of the membrane tube as closely as possible to the top of the inner plastic pipe. This is important because the inner plastic pipe allows the sampler to retain volume during the diffusion process, which drives volume loss during equilibration.
- 3.10 Slide a low-density polyethylene mesh sleeve over the exterior of the filled membrane to prevent abrasion to the membrane during sampler deployment and retrieval.

4. CONTACT OF THE DIALYSIS SAMPLER WITH SEDIMENT SAMPLE

- 4.1. To initiate sediment sampling, arrange buckets on racks in the laboratory for convenient access. Remove the lids from the 5-gallon buckets containing sediments and allow the sediment in the buckets to equilibrate for 2 weeks in the laboratory.
- 4.2. Make sure all buckets are labeled appropriately with sample numbers.
- 4.3. Each bucket should contain about 4 gallons of sediment and about half gallon of overlying water. If the water level is low, add more site water to obtain the right volume of overlying water. Alternatively, artificial salt water matching site salinity (as used inside dialysis samplers) can be used.

4.4 Check the level of water in each bucket every day and add site water as necessary to compensate for evaporation losses during the experiment.

4.5 After 2 weeks of equilibration, insert the dialysis bag samplers vertically into the sediment, such that the top of the sampler is just below the sediment-water interface.

4.6. If multiple samplers are deployed within a single sample bucket, distribute the positions to maximize the amount of sediment between each sampler and between the sampler and the bucket walls.

4.7. Allow the passive samplers to equilibrate within the sediment for a period of 2 weeks.

4.8. Record daily room temperature during the course of the study.

5. PASSIVE SAMPLER REMOVAL, CLEANING, EXTRACTION, ANALYSIS

The method described here is for the extraction and measurement of inorganics and metals.

Passive sampler retrieval and cleaning

5.1. After 2 weeks of contact with sediment, pull the passive samplers from the sediment.

5.2. Gently agitate the passive sampler in the overlying test water to remove loosely adhering sediment particles.

5.3. Rinse the passive sampler with a stream of deionized water, then blot the passive sampler dry with a laboratory tissue.

5.4. Carefully cut open the membrane and pour the fluid contained within the membrane into laboratory-supplied sample containers with the appropriate preservative and label as specified in SOP No. 5 – Containers, Preservation, Handling, and Tracking of Samples for Analysis.

5.5. Place the porewater samples into an ice-chilled cooler and transport samples to the analytical laboratory under chain of custody protocols for analysis.

6. QUALITY ASSURANCE AND QUALITY CONTROL

The following quality assurance/quality control procedures will be performed during the porewater analysis:

- 6.1. All pertinent field information and chains of custody will be provided to the sample processing team. Designated laboratory personnel will review the sample information and confirm that the number of individuals, collection date(s), collection time(s), species, and porewater analyses match the chains of custody. If any questions arise, laboratory personnel will contact the Project Manager and Laboratory Project Manager to resolve.
- 6.2. The laboratory logbook will be checked between steps to verify required information is completed per the next section.
- 6.3. A duplicate sample will be collected for every 20 samples collected and analyzed.
- 6.4. A blank sample of prepared dialysis fluid will be sent for analysis of background levels of target analytes. The blank sample will be exposed to clean deionized water for the duration of the laboratory experiments to check for any exposure to laboratory contaminants.

1-P-QM-QMA-9021767	Laboratory Notebooks, Logbooks, and Documentation for Environmental Testing

Scope:

The colorimetric sulfide method is applicable to the measurement of total and dissolved sulfides in drinking, surface, and saline waters and domestic and industrial wastes. The procedure is applicable at sulfide concentrations between 0.1 and 20 mg/L.

Analysis #10293 uses a sample's dissolved sulfide, pH and ionic strength to calculate the amount of sulfide as H₂S.

Basic Principles:

Sulfide reacts with dimethyl-*p*-phenylene diamine in the presence of ferric chloride to produce methylene blue. Diammonium hydrogen phosphate is added after color development to remove the ferric chloride color. The methylene blue dye is read on a spectrophotometer. The concentration of sulfide is calculated by comparison to a standard curve.

Reference Modifications:

The sulfide concentrations of the curve points for this method are standardized by the titrimetric iodine procedure (EPA Method 376.1) instead of the methylene blue dye solution standardization.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	--	---

There are no procedural differences between SM 20 4500-S2- D and EPA 376.2.

There are no procedural differences between SM 21 4500-S2- D and EPA 376.2.

There are no procedural differences between SM 20 4500-S2- D and SM 21 4500 S2- D.

Definitions:

1. Calibration Blank – reagent water to which all reagents, **except the color indicator reagent**, are added in the same proportions as samples.
2. Method Blank (May also be called a reagent blank) – reagent water that is carried through the same analytical procedure as samples, and to which **all reagents** are added in the same proportions as samples.

Interferences:

Oxygen inadvertently added to the sample may volatilize the sulfide so samples for sulfide analysis must be collected with a minimum of aeration.

Interfering substances such as sulfite, thiosulfate, iodide, and other soluble substances are removed with the addition of zinc acetate to form the precipitate, zinc sulfide.

Sample color and turbidity also may interfere. Correct this by running sample blanks.

Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Revision: 16	Effective date: Jun 2, 2015	Page 5 of 22

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S ₂ B/C/D-2000, 4500-S ₂ F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

NOTE: Adding acid to samples that may contain high concentrations of sulfide must be done in a well-ventilated area to protect laboratory staff from accidental exposure to hydrogen sulfide gas.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability.

Analysts are considered proficient when they have successfully completed a Demonstration of Capability. Demonstration of Capability consists of four check samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation. Demonstration of Capability is performed annually and is maintained in the analyst's training records.

Sample Collection, Preservation, and Handling:

Samples for total sulfide must be collected in a glass container with minimum aeration. Samples must be preserved with zinc acetate and sodium hydroxide (NaOH) to a pH >9. Refrigerate at 0° to 6°C, not frozen, and analyze within 7 days of collection.

Samples for soluble (dissolved) sulfide must be collected in a glass container with minimum aeration. Samples must be preserved with sodium hydroxide (NaOH) to a pH >9. Refrigerate at 0° to 6°C, not frozen, and analyze within 7 days of collection.

Apparatus and Equipment:

1. Spectrophotometer for use at 625 nm with 1-cm cell or equivalent. Refer to 1-P-QM-PRO-9015417.
2. Test tubes with screw type lids or equivalent

--	--	---

3. Assorted automatic pipettes or equivalent. Refer to 1-P-QM-PRO-9015425 and 1-P-QM-PRO-9015426.
4. Analytical balance or equivalent. Refer to 1-P-QM-QMA-9015389.
5. Class A burette with burette stand or equivalent

Reagents and Standards:

Alternate weights and volumes are acceptable as long as final concentrations remain the same. Refer to 1-P-QM-QMA-9017328 for the proper labeling and documentation of reagent preparations.

1. 1+1 sulfuric acid
 - a. In a glass beaker, slowly and carefully add 250 mL of concentrated sulfuric acid (H₂SO₄) to slowly stirring 250 mL of reagent water.
 - b. Solution becomes very hot. Allow time to cool.
 - c. Store in a glass bottle at room temperature and re-evaluate yearly.
2. Amine-sulfuric acid stock solution – Purchased. Store at room temperature and re-evaluate yearly. See manufacturer's label for expiration date.

Or to prepare:

- a. Add 50 mL of concentrated H₂SO₄ slowly and carefully to 20 mL of reagent water.
- b. After solution has completely cooled, dissolve 27.0 ± 0.5 g N,N-dimethyl-*p*-phenylene diamine oxalate in this solution.
- c. Cool and dilute to 100 mL with reagent water in a volumetric flask.

COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

- d. Store in amber glass bottle at room temperature.
 - e. Stable 1 year. (When this stock solution is diluted and used in the procedure, the reagent blank will first be pink and then turn colorless within 3 minutes. If this doesn't happen, discard reagent and remake with fresh oxalate.)
3. Amine-sulfuric acid working reagent
 - a. Dilute 2.5 mL amine-sulfuric acid stock solution to 100 mL with cooled 1+1 H₂SO₄ in a volumetric flask.
 - b. Store in an amber glass bottle at room temperature.
 - c. Stable 6 months.
 4. Ferric chloride solution
 - a. Dissolve 100.0 ± 0.5 g FeCl₃•6H₂O in approximately 40 mL of reagent water.
 - b. Store in an amber glass bottle at room temperature.
 - c. Stable 6 months.
 5. Diammonium hydrogen phosphate solution
 - a. Dissolve 250.0 ± 0.5 g (NH₄)₂HPO₄ in approximately 500 mL of reagent water.
 - b. Store in glass bottle at room temperature.
 - c. Stable 6 months.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

6. Sulfide standard stock solution

- a. Dissolve 3.73 ± 0.01 g Na₂S•9H₂O in reagent water and dilute to 500 mL in a volumetric flask.
- b. Store in glass at 0° to 6°C, not frozen
- c. Stable 7 days. (Concentration of solution is approximately 1000 mg/L.)

NOTE: A separate source of Na₂S•9H₂O must be used when preparing the sulfide standard stock solution used for the calibration curve.

To further clarify, the sodium sulfide used to prepare the 1.0 mg/L LCS and the sodium sulfide used to prepare the calibration curve points must originate from different vendors.

7. 2N zinc acetate solution – Purchased. Store at room temperature. See manufacturer’s label for expiration date. Used to prepare intermediate sulfide solution.
8. 5N sodium hydroxide solution (NaOH)
 - a. Dissolve 200 ± 1 g of NaOH in approximately 800 mL of reagent water.
 - b. Stir well with stir bar. (Solution will get very warm.)
 - c. Dilute to 1000 mL in a volumetric flask.
 - d. Store at room temperature and re-evaluate yearly. Used to prepare sulfide standard intermediate solution.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S ₂ B/C/D-2000, 4500-S ₂ F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

9. Sulfide standard **intermediate** solution

- a. Pipette 20.0 mL of sulfide stock solution into approximately 800 mL of reagent water in a 1000-mL volumetric flask.
- b. Preserve with NaOH to a pH >9 and add approximately 3 mL of purchased 2N zinc acetate solution.
- c. Dilute with reagent water to 1000 mL.
- d. Prepare fresh and standardize daily. (Concentration of solution is approximately 20 mg/L). Used as spiking solution.

10. 5-mg/L Sulfide working standard:

Where:

X = mL of standardized intermediate sulfide solution (diluted to **200 mL** with reagent water in a volumetric flask) needed to obtain a sulfide working standard solution equal to 5 mg/L concentration.

$$X = \frac{1000}{\text{mg/L actual concentration of intermediate sulfide solution}}$$

NOTE: 5 mg/L sulfide working standard must be prepared fresh daily.

11. 0.5 mg/L sulfide CCV

- a. Pipette 10 mL of 5 mg/L sulfide working standard into a 100-mg/L volumetric flask.
- b. Bring up to volume with reagent water.
- c. Prepare fresh daily. Use as prepared for initial CCV.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

12. 1 mg/L sulfide LCS/CCV

- a. Measure 20 mL of 5 mg/L sulfide working standard into a 100-mg/L volumetric flask.
- b. Bring up to volume with reagent water.
- c. Prepare fresh daily.
- d. Use as prepared for LCS and CCV.

13. 1.5 mg/L sulfide CCV

- a. Measure 30 mL of 5 mg/L sulfide working standard into a 100 mg/L volumetric flask.
- b. Bring up to volume with reagent water.
- c. Prepare fresh daily. Use as prepared for CCV.

14. 6N aluminum chloride solution – Purchased, or equivalent. Store at room temperature. See manufacturer’s label for expiration date. Used for dissolved sulfide sample preparation.

Reagents for standardization of sulfide standard intermediate solution:

1. Hydrochloric acid (1+1)

- a. Mix equal portions of concentrated hydrochloric acid (HCl) and reagent water.
- b. Store at room temperature and re-evaluate yearly.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	--	---

2. Starch indicator – Purchased. Store at room temperature. See manufacturer’s label for expiration date.

3. Potassium iodide (KI) crystals – Purchased. Store at room temperature and re-evaluate yearly.

4. 0.025N potassium bi-iodate
 - a. Dry KH(IO₃)₂ for at least 2 hours at 104° ± 1°C and cool approximately one hour in a desiccator.
 - b. Dissolve 0.8124 ± 0.0002 g KH(IO₃)₂ in reagent water and dilute to 1000 mL in a volumetric flask.
 - c. Store in amber glass bottle at room temperature.
 - d. Stable 1 year.

5. 0.1N sodium thiosulfate – Purchased. Store at room temperature. See manufacturer’s label for expiration date.

6. 0.025N sodium thiosulfate (Na₂S₂O₃)
 - a. Dilute 250 mL of 0.1N Na₂S₂O₃ (purchased) to 1000 mL with reagent water.
 - b. Hold time is determined by manufacturer’s expiration date for 0.1N Na₂S₂O₃.
 - c. Store at room temperature.
 - d. Standardize weekly against 0.025N potassium bi-iodate.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

7. 0.025N iodine solution

- a. Dissolve 20 to 25 g KI in approximately 800 mL of reagent water and add 3.20 ± 0.05 g iodine.
- b. Allow plenty of time to dissolve and then dilute to 1000 mL with reagent water in a volumetric flask.
- c. Stable 1 year.
- d. Store in amber glass bottle at room temperature.
- e. Standardize weekly against 0.025N sodium thiosulfate.

Calibration:

- A. Balances must be calibrated each day before use. Refer to 1-P-QM-QMA-9015389.
- B. Pipettes must be checked for accuracy daily per 1-P-QM-PRO-9015426.
- C. Spectrophotometer must be calibrated as per 1-P-QM-PRO-9015417.
- D. Standardization:

Record all standardization in the solution standardization logbook.

1. 0.025N Sodium thiosulfate

- a. Dissolve approximately 2.0 g KI in an Erlenmeyer flask with approximately 150 mL reagent water. Add a few drops of concentrated H₂SO₄. Swirl.
- b. Add by pipette 20 mL of 0.025N potassium bi-iodate.

COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

- c. Dilute to approximately 200 mL with reagent water. Immediately titrate the liberated iodine with 0.025N Na₂S₂O₃ titrant to a pale yellow color.
- d. Add a few drops of starch solution and titrate to the first colorless endpoint.
- e. Perform duplicate trials and average the results.

$$Na_2S_2O_3N = \frac{(20mLKH(IO_3)_2) \times (0.025NKH(IO_3)_2)}{mL \text{ of sodium thiosulfate titrated}}$$

2. 0.025N Iodine

- a. Pipette 10 mL of 0.025N iodine solution into an Erlenmeyer flask.
- b. Add approximately 90 mL of reagent water.
- c. Titrate immediately with the Na₂S₂O₃ (previously standardized) to a pale yellow color.
- d. Add a few drops of starch solution and titrate to the first colorless endpoint.
- e. Perform duplicate trials and average the results.

$$IodineN = \frac{(mL \text{ of } Na_2S_2O_3 \text{ titrated}) (standardized \text{ normality of } Na_2S_2O_3)}{10.0 \text{ mL iodine solution}}$$

3. 20-mg/L intermediate sulfide solution

Add reagents to the Erlenmeyer flask in this order to ensure no sulfide gas is liberated before the titration is performed.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

- a. Pipette 10 mL of iodine solution (previously standardized) into an Erlenmeyer flask.
- b. Add approximately 10 mL of reagent water and approximately 2 mL of 1+1 HCl.
- c. Pipette 100 mL of well-mixed, precipitated 20-mg/L intermediate solution into the flask, discharging it under solution surface. Swirl.
- d. Titrate immediately with Na₂S₂O₃ (previously standardized) to a pale yellow color.
- e. Add a few drops of starch solution and titrate to the first colorless endpoint.
- f. Perform duplicate trials and average the results.

Standardization Calculation:

$$mg/L\ sulfide = \frac{[(A \times B) - (C \times D)] \times 16030}{100mL\ of\ standard}$$

Where:

- A = mL of iodine solution
- B = Normality of iodine solution
- C = mL of Na₂S₂O₃ solution
- D = Normality of Na₂S₂O₃ solution

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

E. Curve (zero spectrophotometer with calibration blank)

1. Prepare a calibration curve every 3 months or when a new reagent is prepared using the sulfide concentrations listed below. Include a reagent blank as part of the curve. Alternate volumes are acceptable as long as the final concentrations remain the same.

Concentration (mg/L)	mL of 5-mg/L standard (diluted to a final volume of 100 mL)
0.00	0 (reagent blank)
0.10	2
0.50	10
1.00	20
1.50	30
2.00	40

2. Zero spectrophotometer with a calibration blank:
 - a. Prepare a calibration blank by pipetting 7.5 mL of reagent water into a 10 mL test tube.
 - b. Add by pipette, 0.5 mL of 1+1 H₂SO₄ and 0.15 mL (3 drops) ferric chloride solution. **Mix immediately by inverting slowly only one time.** Wait 3 to 5 minutes for color development.
 - c. Add by pipette 1.6 mL diammonium hydrogen phosphate solution to test tube. Slowly invert test tube 3×. Wait 10 minutes.
 - d. Zero the spectrophotometer **at 625 nm using a 1 cm cell.**
3. Pipette 7.5 mL of each standard curve point into a 10 mL test tube.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

4. To test tubes, add by pipette, 0.5 mL of amine-sulfuric acid working reagent and 0.15 mL (3 drops) ferric chloride solution. **Mix immediately by inverting slowing only one time.** Mixing too vigorously causes low results by releasing hydrogen sulfide gas before it has had time to react. Presence of sulfide will be indicated by the development of blue color. Wait 3 to 5 minutes for complete color development.
5. Add by pipette 1.6 mL diammonium hydrogen phosphate solution to test tube. Slowly invert test tube 3×. Wait 10 minutes.
6. Read absorbance on spectrophotometer **at 625 nm using a 1-cm cell.**
7. Plot calibration curve of mg/L sulfide concentration vs. absorbance using least squares fit. The correlation coefficient of the curve must be $\geq .995$. When analyzing samples from the state of North Carolina, each analyst performing the analytical procedure must produce a standard curve (Ref 15A NCAC 2H .0805 (a) (7) (I)).

Procedure:

Record data in a raw data logbook following instructions in 1-P-QM-QMA-9021767.

A. Sample Preparation:

1. To remove interferences prior to analysis, zinc acetate preserved samples for total sulfide must be prepared in the following manner:
 - a. Mark on the bottle the volume of the sample.
 - b. After the zinc sulfide precipitate settles out and a clear liquid phase is **visible**, siphon down to the precipitated area (being careful not to pull any of the zinc sulfide precipitate out).
 - c. Refill to the original sample volume mark with reagent water.

Revision: 16	Effective date: Jun 2, 2015	Page 17 of 22
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

- d. Resuspend the precipitate before withdrawing a portion for analysis.
 - e. Sample is no longer considered preserved and needs to be analyzed as soon as possible.
 - f. Samples without a visible precipitated layer must be analyzed without this pretreatment step.
2. Prepare samples for **soluble (dissolved) sulfide** in the following manner:

NOTE: If sample is entirely free from visible suspended solids, dissolved sulfide equals total sulfide. This means the sample is analyzed without the following pretreatment step.

- a. Add approximately 4 drops (0.2 mL) of 6N aluminum chloride solution to a 100-mL glass bottle.
- b. Fill the bottle with sample (pH adjusted to >9 with NaOH) and add approximately 4 drops of 6N aluminum chloride solution.
- c. Mix well to flocculate contents.
- d. Increase amount of aluminum chloride, if needed, to get good clarification without using excessively large amounts and to adjust the pH to between 6 and 9.
- e. Let settle until a reasonably clear supernatant is visible.
- f. Analyze supernatant as soon as possible.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

B. Sample Analysis

1. Zero spectrophotometer with a calibration blank:
 - a. Prepare a calibration blank by pipetting 7.5 mL of reagent water into a 10 mL test tube.
 - b. Add by pipette, 0.5 mL of 1+1 H₂SO₄ and 0.15 mL (3 drops) ferric chloride solution. **Mix immediately by inverting slowing only one time.** Wait 3 to 5 minutes for color development.
 - c. Add by pipette 1.6 mL diammonium hydrogen phosphate solution to test tube. Slowly invert test tube 3×. Wait 10 minutes.
 - d. Zero the spectrophotometer **at 625 nm using a 1-cm cell.**
2. Using a wide-tipped pipette, place 7.5 mL of sample or 7.5 mL of a suitable dilution of sample each into two 10-mL test tubes, one for the sample and the other for a sample blank.
3. First tube,
 - a. Add by pipette, 0.5 mL of amine-sulfuric acid working reagent and 0.15 mL (3 drops) ferric chloride solution.
 - b. **Mix immediately by inverting slowing only one time.** Mixing too vigorously causes low results by releasing hydrogen sulfide gas before it has had time to react. Presence of sulfide will be indicated by the development of blue color.
 - c. Wait 3 to 5 minutes for complete color development.

Revision: 16	Effective date: Jun 2, 2015	Page 19 of 22
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

4. Sample blank

- a. Each sample requires a sample blank to subtract interferences.
 - b. Add by pipette, 0.5 mL of 1+1 H₂SO₄ and 0.15 mL (3 drops) ferric chloride solution.
 - c. **Mix immediately by inverting slowing only one time.**
 - d. Wait 3 to 5 minutes for complete color development.
5. Add by pipette 1.6 mL diammonium hydrogen phosphate solution to test tube. Slowly invert test tube 3×. Wait 10 minutes.
6. Read absorbance on spectrophotometer **at 625 nm using a 1-cm cell.**

Calculations:

A. Colorimetric Sulfide and Dissolved Sulfide

Subtract the sample blank absorbance from the sample absorbance and obtain concentration of sulfide in mg/L from calibration curve. Multiply this value by sample dilution factor to calculate mg/L sulfide concentration in sample.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	---	--

B. Sulfide as H₂S

The sample's specific conductance, pH, and dissolved sulfide value are necessary to determine sulfide as H₂S for a sample. Using the 20°C column, determine the ionization constant from Table 4500-S²⁻:I found on page 4-128 of SM 4500-S²⁻ F (18th ed.) Subtract the constant from the pH value. Use this value to determine the percentage (J) of dissolved sulfide present as H₂S from the graph (Figure 4500-S²⁻:2) on page 4-128 of SM 4500-S²⁻ F (18th ed.). Multiply the dissolved sulfide value by the percentage (J) to give the amount of sulfide as H₂S in a sample:

$$J \times (\text{dissolved sulfide}) = \text{sulfide as H}_2\text{S}$$

Statistical Information/Method Performance:

The method detection limit (MDL) is determined annually by following the procedure outlined in 1-P-QM-QMA-9017309. For this analysis, the MDL study must be analyzed over a minimum of 3 days.

The quality control acceptance windows are generated annually by following the procedure outlined in 1-P-QM-QMA-9017313.

Quality Assurance/Quality Control:

A method blank and a 1.0-mg/L laboratory control standard (LCS) must be analyzed on each batch. Batch size is limited to 20 samples or less.

The method blank must be less than half the LOQ for this analysis.

A continuing calibration verification (CCV) standard must be analyzed at the beginning of each batch, after every ten samples and at the end of each batch. The concentration of the CCV must alternate in a repeating wave pattern: 0.5 mg/L, 1.0 mg/L, 1.5 mg/L, 1.0 mg/L, 0.5 mg/L, etc. On each batch, at least one 0.5-mg/L CCV must be analyzed to validate the curve. The acceptance range for all CCVs is 90% to 110%.

 Lancaster Laboratories Environmental	Document Title: Colorimetric Sulfide in Waters (#0230), Sulfide as H ₂ S (#10293 Calculation), Dissolved Sulfide in Waters (#10499) by 4500-S2 B/C/D-2000, 4500-S2 F-2000, or EPA 376.2	Eurofins Document Reference: 1-P-QM-WI -9011642
--	--	--

A matrix spike (MS), a matrix spike duplicate (MSD), and a sample matrix duplicate must be analyzed with each batch.

When sample volume does not permit the analysis of either a sample matrix duplicate or an MS and an MSD, then a 1.0 mg/L LCSD must be analyzed to demonstrate method precision.

A second sample matrix duplicate is not required unless a batch contains an NPDES sample(s) from South Carolina and the batch contains more than 10 samples.

Samples from West Virginia require a usable precision measurement for each batch. Analyzing one of the following on a batch containing a West Virginia sample fulfills this requirement: an MS/MSD, a non-program deleted duplicate, or an LCSD.

Refer to 1-P-QM-PRO-9015535 for requirements that fall under Chapter 4 of Standard Methods for the Examination of Waters and Wastewaters, 22nd Edition.

If any of the QC samples do not meet required specifications, refer to 1-P-QM-PRO-9015535. Follow guidelines in 1-P-QM-PRO-9015535 for outlier QC data and for corrective action. See LIMS for current quality control acceptance windows.

Purpose:

This procedure provides instructions on the determination of Ammonia nitrogen in waters and soils.

Scope:

This method is for the determination of Ammonia nitrogen in drinking and waste waters as well as soils. The samples are preserved at the time of collection in sulfuric acid. The holding time for this analysis is 28 days. Refer to the LIMS for the current MDL and LOQ values.

Revision: 2	Effective date: Jul 19, 2013	Page 3 of 16
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Automated Determination of Ammonia Nitrogen in Water and Wastewater Using Segmented Flow Analysis and Gas Diffusion by EPA 350.1	Eurofins Document Reference: 1-P-QM-PRO-9020808
--	--	--

Basic Principles:

This method is for the determination of Ammonia nitrogen in waters and soils. The sample pH is raised to a pH of >11, and the ammonia molecules generated pass through a gas diffusion membrane and are absorbed in an alkaline hypochlorite solution. The sample then reacts with salicylate and sodium nitroferricyanide to form an indophenol blue complex. The colored complex is measured at 660 nm and quantified against a standard curve.

Interferences:

Eliminate suspended particulates and ionic interferences by filtering through a .45µm filter. Sample with high background absorbance do not interfere because color will not diffuse through the membrane. Heavy metals in the sample may interfere by precipitating. Complexion with citrate will remove these interferences. Residual chlorine must be removed by pretreatment of the sample prior to analysis.

Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Normal laboratory practices must be followed. Special care must be taken when preparing concentrated basic or acid solutions. Perform all the preparations in a hood. Avoid skin contact or breathing the vapors from any of the reagents used or samples to be analyzed. Use extreme caution when handling the digests due to the mercury and sulfuric acid used in the digestion procedure. Dispose of waste digests in the appropriate waste-acid collectors. Discard or send for repair any glassware that is chipped, flawed, or broken.

--	---	---

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability(DOC).

Analysts are considered proficient when they have successfully completed a DOC. DOC consists of four check standards that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation. DOC is performed annually and is maintained in the analyst's training records.

Sample Collection, Preservation and Handling:

Water samples must be acidified at the time of collection to a pH <2 using sulfuric acid. They are collected in either plastic or glass containers. The holding time from collection to analysis is 28 days. Residual chlorine must be removed by pretreatment with ascorbic acid. This is completed in the Preservation area upon the sample's receipt.

Apparatus and Equipment:

An automated flow analyzer is required for this method. The flow analyzer consists of the following parts:

- A. OI automatic sampler (Model 3090) or equivalent
- B. OI multichannel dispenser (Model ISM938E) or equivalent
- C. OI TKN/Ammonia cartridge and pump tubing (Part # 323657)
- D. OI UV detector (Model FS3100)
- E. PC with OI Analytical WinFlow TM software

 Lancaster Laboratories Environmental	Document Title: Automated Determination of Ammonia Nitrogen in Water and Wastewater Using Segmented Flow Analysis and Gas Diffusion by EPA 350.1	Eurofins Document Reference: 1-P-QM-PRO-9020808
--	--	--

Reagents and Standards:

NOTE: All chemicals used must be ACS reagent grade unless otherwise noted.

See 1-P-QM-QMA-9017328, for the appropriate labeling and documentation of reagent and standard preparation.

Different volumes or weights may be used in the preparation of reagents or standards as long as the ratios remain equivalent.

A. Stock sodium hydroxide solution, 10 N

Sodium hydroxide (NaOH)	400 g
-------------------------	-------

1. Slowly add 400 g of sodium hydroxide to approximately 600 mL reagent water.
2. Cool to room temperature and dilute to 1 L with reagent water.
3. Stable for 6 months
4. Store in a plastic gallon jug at room temperature.

B. Sodium salicylate/sodium nitroprusside solution

10N Sodium Hydroxide	250mL
Sodium salicylate (C ₆ H ₄ (OH) COONa)	150 ± 1.0 g
Sodium nitroprusside	0.3 ± 0.01 g

1. While stirring, slowly add 250mL of 10N sodium hydroxide solution to approximately 700mL of reagent water in a 1-L volumetric flask.
2. Dissolve 150 ± 1.0 g of sodium salicylate and 0.3 ± 0.01 g of sodium nitroprusside in about 800 mL of reagent water in a 1000-mL volumetric flask.

Revision: 2	Effective date: Jul 19, 2013	Page 6 of 16
COMPANY CONFIDENTIAL		

	Lancaster Laboratories Environmental	Document Title: Automated Determination of Ammonia Nitrogen in Water and Wastewater Using Segmented Flow Analysis and Gas Diffusion by EPA 350.1	Eurofins Document Reference: 1-P-QM-PRO-9020808
---	---	--	--

3. Dilute to volume with reagent water.
4. Stable for 30 days.
5. Store in an amber bottle at room temperature.

NOTE: At the end of the run, this reagent must be removed first. Continue pumping with other reagents on-line for 10 minutes, then proceed with shutdown procedure.

C. Sodium hypochlorite solution

10N NaOH	1 mL
Sodium hypochlorite (bleach)	2 mL

Add 1mL of 10N NaOH and 2mL bleach to 800mL of reagent water in a 1-L volumetric flask. Dilute to volume. Prepare fresh daily.

D. Complexing reagent

Sodium Citrate	112 ± 0.8 g
10N NaOH	320 mL

1. While stirring add 112 ± 0.8 g of Sodium Citrate to approximately 200mL of reagent water in a 1-L volumetric flask.
2. Add 320mL of 10N NaOH solution
3. Dilute to volume with reagent water.
4. Cool to room temperature.
5. Stable for 30 days.

6. Store in an amber bottle at room temperature.

E. Calibration stock standard, 1000 mg/L ammonia nitrogen as N

Anhydrous ammonium chloride (NH ₄ Cl) (dried at 102° to 107°C for approximately 1 hour)	3.819 ± 0.005 g
Sulfuric acid (H ₂ SO ₄)	0.5 mL

1. Dissolve 3.819 ± 0.005 g of anhydrous ammonium chloride in approximately 800 mL of reagent water containing 0.5-mL sulfuric acid.
2. Dilute to 1000 mL with reagent water.
3. Stable for 30 days.
4. Store in a glass bottle at 0° to 6°C, not frozen

F. Quality-control stock standard, 1000 mg/L ammonia nitrogen as N

Use the same procedure as for the calibration stock standard using anhydrous ammonium chloride from a different source.

Calibration:

Cal ID:	mg/L
S1	2.0
S2	1.5
S3	1.0
S4	0.5
S5	0.1
S6	0.05

Procedure:

1. Configure the Instrument with the TKN/Ammonia cartridge and pump tubes according to Figure 2.

 Lancaster Laboratories Environmental	Document Title: Automated Determination of Ammonia Nitrogen in Water and Wastewater Using Segmented Flow Analysis and Gas Diffusion by EPA 350.1	Eurofins Document Reference: 1-P-QM-PRO-9020808
--	--	--

2. Using Table I as a guide for the Model FS3100 detector set up the pump, the detector, the sampler, and data system.
3. Place the sample and complexing reagent line in reagent water and the sodium salicylate line in the Brij-35 wash solution. Turn ON the pump and adjust the tension on the pump tube harnesses to obtain a flow through each tube. Wash the system with reagent for at least 10 minutes.
4. Place all reagents on-line and pump at least 10 minutes.
5. Load Winflow software. In the sample table section load the NH3 table. Table II shows the order in which the calibration standards, blanks, and quality control standards must be analyzed to calibrate and verify that the analytical system is in control. Add all samples and QC to the table, save and exit.
6. Enter the Collect section and select the NH3 table and method. Save the file using a two digit year followed by the Julian day and the NH3 designation.

e.g., 03 090 NH3
 ↑ ↑
 Year Julian day

7. Click the run button and allow for the system to stabilize the baseline. Once a stable baseline is observed click the stop button. Wait for the sample probe to reset and click the rewind button. Once again click the run button until a baseline is observed and then click the forward button to begin collecting data.
8. Filter any sample that has a high amount of suspended matter.

NOTE: Any sample that must be filtered also needs a PBW and LCSW filtered for that batch.

	Lancaster Laboratories Environmental	Document Title: Automated Determination of Ammonia Nitrogen in Water and Wastewater Using Segmented Flow Analysis and Gas Diffusion by EPA 350.1	Eurofins Document Reference: 1-P-QM-PRO-9020808
---	---	--	--

9. Start the auto sampler and begin acquiring data. The data system will recognize the "Sync" peak and activate data collection. A standard with a concentration $> \frac{1}{2}$ the highest calibration standard is used in the Sync position.
10. Once the calibration standards have been analyzed, check the linearity of the calibration. The coefficient must be > 0.995 for the curve to be acceptable.
11. Once the calibration is acceptable, continue to analyze samples with the appropriate laboratory control standard (LCS) and preparation blank (PB). Analyze a calibration verification standard (CCV) and calibration blank (W) between every **ten** injections.
12. Any sample that falls above the highest standard of the full-scale calibration must be diluted with reagent water and reanalyzed. The raw result of the diluted sample must have a value of at least 10% of the highest calibration standard. Samples which have been digested at a reduced weight or volume and fall below 10% of the full-scale calibration must be digested at a higher volume or weight unless there is a sample matrix or volume problems.
13. Shutdown process – End the run with a calibration verification standard and calibration blank. Place all lines in reagent water for at least 15 minutes. Turn OFF the system.

NOTE: This procedure uses a gas diffusion membrane, before each run ensure to check the membrane for and visible tears or corrosion.

Revision: 2	Effective date: Jul 19, 2013	Page 10 of 16
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Automated Determination of Ammonia Nitrogen in Water and Wastewater Using Segmented Flow Analysis and Gas Diffusion by EPA 350.1	Eurofins Document Reference: 1-P-QM-PRO-9020808
--	---	---

Calculations:

The data system automatically prepares a standard curve (first order-linear) by plotting peak heights of standards against their concentrations. The concentration of ammonia nitrogen in the samples is calculated by comparing the peak height to the standard curve. The following equation is used to get the final nitrite nitrogen result (calculated automatically by the software).

$$(NH_3 - N)(mg/L) = (raw\ result) \times (dilution\ factor)$$

Statistical Information/Method Performance:

1. The method detection limit (MDL) must be determined every 6 months for waters by following the procedure outlined in 1-P-QM-QMA-9017309. For soils, the MDL is determined annually.
2. The quality control acceptance windows are generated annually by following the procedure outlined in 1-P-QM-QMA-9017313.

Quality Assurance/Quality Control:

1. A calibration curve of six standards and a blank must be run at the beginning of every run. The correlation coefficient of the curve must be >0.995. If this is not met the calibration is unacceptable and must be rerun. The blank is not used in the correlation coefficient calculation.
2. A calibration verification standard (ICV) (1.0 mg/L NH3) must be run immediately after every calibration. The acceptable range is ± 10% of the true value. If the ICV does not meet this acceptance criterion, see 1-P-QM-PRO-9015459 for handling outliers and the appropriate corrective action that must be taken.

	Lancaster Laboratories Environmental	Document Title: Automated Determination of Ammonia Nitrogen in Water and Wastewater Using Segmented Flow Analysis and Gas Diffusion by EPA 350.1	Eurofins Document Reference: 1-P-QM-PRO-9020808
---	---	--	--

3. A calibration blank (W) must be run after the ICV. The acceptable result is < the method detection limit. If the calibration blank does not meet this requirement, see 1-P-QM-PRO-9015459 for handling outliers and the appropriate corrective action that must be taken.

4. A calibration verification standard (CCV) and a calibration blank (W) must be run every 10 injections. The acceptable range for the CCV is $\pm 10\%$ of the true value. An acceptable calibration blank result is < the MDL. If a CCV and/or CCB result does not meet the requirements, see 1-P-QM-PRO-9015459 for handling outliers and the appropriate corrective action that must be taken.

5. A batch must contain no more than 20 field samples plus associated QC samples (LCS, PB, duplicate, spike).

6. An LCS must be prepared and analyzed with every batch of samples prepared. For waters, the acceptable range of the LCS is 90% to 110% of the true value. If the LCS does not meet this acceptance criterion, see 1-P-QM-PRO-9015459 for handling outliers and the appropriate corrective action that must be taken. For soils, the acceptable range of the LCS is based on a statistical window.

7. Based upon client requirements, when appropriate, a laboratory control standard duplicate (LCSD) is also be prepared and analyzed under the same conditions as the LCS. The acceptable range of the LCSD is the same as that for the LCS. The RPD between the LCS and LCSD is statistical and is found in the LIMS. If the LCSD does not meet this acceptance criterion, see 1-P-QM-PRO-9015459 for handling outliers and the corrective action that must be taken.

8. A batch blank (PB) must be prepared and analyzed with every batch of samples prepared. The acceptable result is < the method detection limit. If the batch blank does not meet this criterion, see 1-P-QM-PRO-9015459 for handling outliers and the appropriate corrective action that must be taken.

 Lancaster Laboratories Environmental	Document Title: Automated Determination of Ammonia Nitrogen in Water and Wastewater Using Segmented Flow Analysis and Gas Diffusion by EPA 350.1	Eurofins Document Reference: 1-P-QM-PRO-9020808
--	---	---

9. A duplicate must be prepared and analyzed for every 10 samples (10% frequency). The acceptable RPD is statistical and is found in the LIMS. If this acceptance criterion is not met, see 1-P-QM-PRO-9015459 for handling outliers and the appropriate corrective action that must be taken.

10. A matrix spike must be prepared and analyzed every 10 samples. The acceptance range is 90% to 110% recovery for waters. For soils the acceptance range is statistical. If the spike recovery does not meet this acceptance criterion, see 1-P-QM-PRO-9015459 for handling outliers and the appropriate corrective action that must be taken.

11. Upon client request, when appropriate, a matrix spike duplicate is also prepared and analyzed under the same conditions as the matrix spike. The acceptance window for the MSD is the same as for the MS. The RPD between the MS and MSD is statistical and is found in the LIMS. If the RPD falls outside these criteria, consult your group leader or manager to determine if reanalysis is necessary.

12. The linearity of the calibration must be determined every 6 months by analyzing a blank and three standards. If any verification data exceeds the initial values by $\pm 10\%$, linearity must be reestablished. The values of the three standards are taken from the calculated values of the standards used for the calibration curve.

Document	Document Title
1-P-QM-QMA-9017309	Determining Method Detection Limits and Limits of Quantitation
1-P-QM-QMA-9017313	Establishing Control Limits
1-P-QM-QMA-9017328	Reagents and Standards

Scope:

This method is applicable for the determination of total organic carbon in water and wastewaters. The procedure outlined in this method pertains to the O.I. Model 1030 analyzer. This model uses the persulfate oxidation technique and references SM 5310C. The limit of quantitation (LOQ) for this analysis can be found in the sample information file.

Analysis 7547 is used for analysis of dissolved organic carbon. These samples are passed through a 0.45- μ membrane filter prior to analysis. Analysis 6090 is used for the determination of total inorganic carbon. It can be performed by calculating the difference between total carbon and TOC.

Revision: 15	Effective date: May 22, 2015	Page 3 of 12
COMPANY CONFIDENTIAL		

	Lancaster Laboratories Environmental	Document Title: Determination of Total Organic Carbon, Dissolved Organic Carbon, and Inorganic Carbon in Water and Wastewater	Eurofins Document Reference: 1-P-QM-WI -9011651
---	---	--	--

Basic Principles:

A sample aliquot of water or wastewater is injected into a reaction vessel at 100°C where metered amounts of phosphoric acid are added. The sample is purged with ultrapure nitrogen gas to remove inorganic carbon as carbon dioxide and any purgeable organic carbon (POC). Following the purging of the inorganic fraction, a metered amount of sodium persulfate is added to the reaction vessel, and the sample is heated. The persulfate oxidizes any organic carbon to carbon dioxide. Following the completion of the persulfate digestion, the carbon dioxide is carried to the IR detector by the nitrogen stream.

Reference Modifications:

There are no procedural differences between EPA 415.1 and SM20 5310C.

Interferences:

This method is generally free of interferences when normal wastewater and water samples are analyzed. However, high concentrations of chloride can interfere and several other problems can arise from certain sample matrices. These are listed below.

1. Chloride can react with the persulfate, which can cause erroneously low TOC results. Samples high in chloride may require that extra persulfate be added and the reaction time extended. The chlorine gas that is produced is also damaging to the molecular sieve. For these reasons, samples must not be preserved with hydrochloric acid.
2. Samples with high levels of inorganic carbon may require extra acid and longer purge time to ensure all the carbonates and bicarbonates are removed from the sample. A smaller sample volume may also be used.

	Lancaster Laboratories Environmental	Document Title: Determination of Total Organic Carbon, Dissolved Organic Carbon, and Inorganic Carbon in Water and Wastewater	Eurofins Document Reference: 1-P-QM-WI -9011651
---	---	---	---

3. Samples with high levels of organic carbon may require that extra sodium persulfate be added and that the reaction time is extended to ensure that all the organic carbon is oxidized by the persulfate. A smaller sample volume may also be used. Spiking the sample with a known amount of carbon and calculating recovery can be used to verify the oxidation efficiency.

4. When sequentially analyzing samples, carryover may occur when a sample high in carbon is followed by a sample low in carbon. This will produce erroneously high results for low-level TOC samples. This is caused by adsorption of organic carbon on the Teflon™ tubes and overloading of the molecular sieve. If an excessively high-level sample is accidentally introduced into the system, it may be necessary to clean the digestion vessel with reagent water before analyzing any more samples. This is accomplished by cycling reagent water and the reagents through the system until TOC values drop to less than the normal detection limit.

Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state, and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Normal laboratory safety practices must be followed when performing this method. Extra care must be taken when handling the persulfate reagent (which is a strong oxidant) and unknown samples that could contain toxic or carcinogenic chemicals. Inspect all glassware before use. Discard or send for repair any glassware that is chipped, flawed, or broken.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability.

Revision: 15	Effective date: May 22, 2015	Page 5 of 12
COMPANY CONFIDENTIAL		

	Lancaster Laboratories Environmental	Document Title: Determination of Total Organic Carbon, Dissolved Organic Carbon, and Inorganic Carbon in Water and Wastewater	Eurofins Document Reference: 1-P-QM-WI -9011651
---	---	---	---

Demonstration of Capability consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. This is performed annually and is maintained in the analyst's training records.

Sample Collection, Preservation, and Handling:

All samples must be collected in glass containers and stored at 0° to 6°C not frozen. Samples for TOC must be acidified with concentrated phosphoric acid to a pH <2. The holding time for these samples is 28 days.

Apparatus and Equipment:

1. O.I. Corporation Model 1030 TOC analyzer
2. O.I. Corporation Model 1088 Rotary Autosampler
3. Printer
4. 2-stage gas regulator
5. Analytical balance capable of accurately weighing to 0.0001 g
6. Automatic pipettes
7. Glassware – general laboratory glassware is needed for preparing reagents, standards, sample dilutions, etc.

Reagents and Standards:

NOTE: All chemicals used must be ACS reagent grade unless otherwise noted.

Different volumes or weights may be used provided the ratios remain equivalent.

See 1-P-QM-QMA-9017328 for the appropriate labeling and documentation of reagent and standard preparation.

Revision: 15	Effective date: May 22, 2015	Page 6 of 12
COMPANY CONFIDENTIAL		

	Lancaster Laboratories Environmental	Document Title: Determination of Total Organic Carbon, Dissolved Organic Carbon, and Inorganic Carbon in Water and Wastewater	Eurofins Document Reference: 1-P-QM-WI -9011651
---	---	--	--

1. Ultra-pure nitrogen gas (30 psi)

2. Oxidizing reagent

Sodium persulfate (Na₂S₂O₈) 100 g

- a. Dissolve 100 ± 1 g of sodium persulfate in approximately 500 mL of reagent water in a 1000-mL volumetric flask.
- b. Dilute to volume with reagent water.
- c. Purge with nitrogen gas for 1 hour to release inorganic carbon present in reagent.
- d. This solution is stable for 6 months and is stored at room temperature in a plastic container.

3. Phosphoric acid (5% w/w)

Phosphoric acid, 85% (H₃PO₄) 59 mL

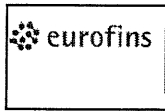

- a. Add 59 mL of 85% H₃PO₄ to about 500 mL of reagent water in a 1000-mL volumetric flask.
- b. Mix thoroughly and dilute to volume with reagent water.
- c. This solution is stable for 6 months and is stored at room temperature in a plastic container.

4. Total Inorganic Standard (500 mg/L)

Sodium bicarbonate (NaHCO₃) 0.1750 g ±0.0005 g

Sodium carbonate (Na₂CO₃) 0.2209 g ±0.0005 g

Revision: 15	Effective date: May 22, 2015	Page 7 of 12
COMPANY CONFIDENTIAL		

	Lancaster Laboratories Environmental	Document Title: Determination of Total Organic Carbon, Dissolved Organic Carbon, and Inorganic Carbon in Water and Wastewater	Eurofins Document Reference: 1-P-QM-WI -9011651
---	---	--	--

- a. Dissolve above reagents in a 100-mL volumetric flask containing about 50 mL of reagent water.
- b. Dilute to volume with reagent water.
- c. Prepare monthly. Do not acidify. Store in the flask at 0° to 6°C not frozen.

Calibration:

1. TOC stock calibration standard (500 mg C/L)

Potassium hydrogen phthalate (KHP) 1.063 ± 0.005 g

Phosphoric acid, concentrated (H₃PO₄) 20 drops

- a. Add 20 drops of concentrated phosphoric acid (H₃PO₄) to a 1000-mL volumetric flask containing about 500 mL of reagent water.
- b. Dissolve 1.063 ± 0.005 g of KHP to the flask and dilute to volume with reagent water.
- c. Prepare every 30 days. Store in an amber glass bottle at 0° to 6°C not frozen.

2. TOC stock QC standard (500 mg C/L)

Prepare identically to TOC stock calibration standard using KHP from a different source.

3. Working standards for calibration and QC

Pipette a volume of TOC stock standard into the appropriate volumetric flask that contains reagent water and three drops of concentrated phosphoric acid. Dilute to volume with reagent water. Prepare daily, as needed, according to the following table:

Revision: 15	Effective date: May 22, 2015	Page 8 of 12
COMPANY CONFIDENTIAL		

Volume Stock CAL Standard (mL)	Standard Concentration (mg/L)	Final Volume (mL)
20	100	100
10	50	100
10	25	200
2.0	10	100
3.0	7.5	200
0.2	1.0	100
Volume Stock QC Standard (mL)	Standard Concentration (mg/L)	Final Volume (mL)
10.0	25 –CCV2/LCSW	200

Procedure:

General (more detailed instructions for each step can be found in the instrument manual)

Start up the instrument in the following manner:

1. Turn on the power switch located at the back of the instrument. The system loads the startup screen and User Login dialog box. Turn on the nitrogen gas flow.
2. Prime the syringe and all reagents by following the manufacturer's instructions located in the instrument manual.
3. Load the active sequence.
4. Each sample is injected in duplicate. The RPD of the duplicate injections must be <10% when the concentrations are greater than five times the LOQ.
5. For Dissolved Organic Carbon, the samples and all quality control samples are filtered through a 0.45 micron filter that has been rinsed two times with reagent water. There is no subtraction of the filter blank in the calculation for DOC.

	Lancaster Laboratories Environmental	Document Title: Determination of Total Organic Carbon, Dissolved Organic Carbon, and Inorganic Carbon in Water and Wastewater	Eurofins Document Reference: 1-P-QM-WI -9011651
---	---	--	--

6. Load samples onto the autosampler trays.

7. Press Start.

Calculations:

The TOC result (in mg/L) is performed as below using the average of the two injections:

$$raw\ result\ (mg/L\ from\ instrument) \times dilution\ factor = final\ TOC\ result\ (mg/L)$$

Statistical Information/Method Performance:

1. The method detection limit (MDL) is determined annually by following the procedure outlined in 1-P-QM-QMA-9017309. The 7 replicates must be analyzed over a period of at least 3 days.
2. The quality control acceptance windows are generated annually by following the procedure outlined in 1-P-QM-QMA-9017313.

Quality Assurance/Quality Control:

1. A calibration of 6 standards and a reagent water blank must be run monthly as the instrument calibration. The correlation coefficient of the curve must be ≥ 0.995 .
2. An initial calibration blank (ICB) and an initial calibration verification standard (ICV) must be run after every calibration. The acceptable result is $<$ the LOQ for the ICB and $\pm 10\%$ for the ICV.
3. A CCV and CCB must be analyzed after every 10 injections. The acceptable range for the CCV is $\pm 10\%$ of the true value. An acceptable CCB result is $<$ the LOQ. If a CCV or CCB does not meet the acceptance criterion, all samples since the last compliant CCV and CCB and all samples before the next compliant CCV and CCB must be reanalyzed.

	Lancaster Laboratories Environmental	Document Title: Determination of Total Organic Carbon, Dissolved Organic Carbon, and Inorganic Carbon in Water and Wastewater	Eurofins Document Reference: 1-P-QM-WI -9011651
---	---	--	--

4. Sample results must not exceed the concentration of the highest standard. If a sample result falls above this value, the sample must be diluted and run again.
5. A batch must contain no more than 20 samples.
6. A batch blank (PBW) must be analyzed every batch. An acceptable result is less than ½ the LOQ. If the batch blank does not meet this criterion, corrective action must be taken, documented, and the PBW rerun twice. If the blank result is still greater than ½ the LOQ, any samples associated with the unacceptable PBW must be reanalyzed with an acceptable PBW once the analysis is back in control.

NOTE: The batch blank analyzed is a reagent water blank.

7. A laboratory control standard (LCSW) must be analyzed every batch. The LCSW is the 25 mg/L CCV2 standard. The acceptable range for this standard is statistical. See LIMS for current acceptance range. If the LCSW does not fall within the acceptable range, corrective action must be taken, documented, and the LCSW rerun twice. If the LCSW result is still unacceptable, any samples associated with the unacceptable LCSW must be reanalyzed with an acceptable LCSW.
8. Based upon client requirements, a laboratory control standard duplicate (LCSWD) is prepared and analyzed under the same conditions as the LCSW. The acceptance criterion for the LCSWD is the same as that of the LCSW. The relative percent difference between the LCSW and LCSWD is calculated by the LIMS statistical program. If the RPD is outside of specifications, see your group leader to determine if a reanalysis is required.
9. A duplicate must be analyzed every batch at a frequency of 1 duplicate per 10 samples. The acceptance criterion is calculated by the LIMS statistical program. If the relative percent difference falls outside of the acceptance criteria, see your group leader to determine if reanalysis is needed.

	Lancaster Laboratories Environmental	Document Title: Determination of Total Organic Carbon, Dissolved Organic Carbon, and Inorganic Carbon in Water and Wastewater	Eurofins Document Reference: 1-P-QM-WI -9011651
---	---	---	---

10. A matrix spike must be analyzed at a frequency of 1 spike per 10 samples. This spike must be prepared at a concentration level that is at least four times greater than the concentration of the unspiked sample. See LIMS for current quality control acceptance criteria. If the recovery is outside of the acceptance criteria, consult your group leader to determine if reanalysis is necessary.

11. Based upon client requirements, a MSD is prepared and analyzed under the same conditions as the MS. The acceptance criteria and corrective action are the same as the MS. The relative percent difference between the MS and MSD is statistical and can be found in the LIMS. If the RPD is outside of these criteria, consult your group leader to determine if reanalysis is necessary.

12. The instrument must be calibrated at least every 30 days, or whenever acceptable check standards can no longer be obtained. At any point where the instrument has been idle for a period of 4 hours or more, a CCB and CCV must be analyzed. If either of these parameters is not within specifications, the instrument must be recalibrated and a new run started.

13. A Total Inorganic Carbon (TIC) check standard must be prepared daily to determine the efficiency of inorganic carbon removal when performing the total organic carbon analysis. The LCSW sample must be spiked with the same level of TIC and analyzed with each run. The acceptable range for this spike is 80%-120%.

No. L-45

**Sediment/Porewater Oxidation-Reduction Potential Monitoring
Protocol ORP-SED-1**

SEDIMENT/POREWATER OXIDATION-REDUCTION POTENTIAL MONITORING

1. TEST OBJECTIVE

To assess the oxidation-reduction potential (ORP) of a sediment/porewater sample.

2. INTERFERENCES

Organic matter and hydrogen sulfide can cause contamination and coating of redox electrodes. Solutions containing chromium, uranium, vanadium or titanium ions or other ions that are stronger reducing agents than hydrogen or platinum may yield unstable readings.

3. TEST EQUIPMENT

- Environmental chamber capable of maintaining target test temperature, lighting and photoperiod.
- Glassware (graduated cylinders, 3-L pitchers, volumetric flasks, pipettes, beakers identical to beakers used in bioaccumulation and toxicity testing experiments)
- ORP probe
- Oil free air supply for supplying test solutions if needed or to aerate samples with supersaturated dissolved oxygen levels

4. CALIBRATION

The ORP probe should be calibrated per USEPA Operating Procedure Number SESDPROC-113-R1, Field Measurement of Oxidation Reduction Potential (ORP).

5. TEST ARTICLE

5.1 Description/Identification

The test material will be an aliquot of sediment paired to sediment to be tested for bioaccumulation and toxicity. The test article is a whole sediment sample.

5.2 Sample Collection, Preservation, Shipment and Storage

The sediment will be processed and handled identically to the paired sediment to be tested for bioaccumulation and toxicity.

6. EXPERIMENTAL DESIGN

Five test chambers will be prepared containing sediment from each of 5 sampling stations to

monitor ORP during the seven day equilibration period and throughout the bioaccumulation and toxicity testing period (approximately 28 days).

6.1 Test Vessels and Test Volume

Test vessels will consist of 1-L exposure beakers containing 100-200 ml of sediment and 400-800 ml of overlying water (typically 1:4 ratio of sediment to overlying water). The size of the test vessels, and the volume of sediment and overlying water may be changed consistent with the paired sediments being tested for bioaccumulation and toxicity.

6.2 Overlying Water

Overlying water will match the overlying water used for the paired bioaccumulation and toxicity tests.

6.3 Test Environment

The test vessels are maintained in an environmentally controlled laboratory with a 16-hour light, 8-hour dark photoperiod. Temperature within the environmental room is monitored continuously using temperature recorders and is maintained at $20\pm 1^{\circ}\text{C}$ (unless a different project-specific temperature is required).

Seven days before test initiation, the sediment is loaded into the test chambers and overlying water is carefully added to each chamber. This seven day period will serve as the equilibration period for the test chambers. Daily ORP measurements will begin on day one of the seven day equilibration period and will continue daily through the end of the 28-day experiment period.

Aeration may be provided to each test vessel, consistent with the aeration provided to the paired sediment being tested for bioaccumulation and toxicity, through a 1-ml glass pipet, placed no closer than 2 cm above the sediment surface.

6.4 Test Observations

The overlying water in the test chambers is replaced a minimum of three times a week (e.g., Monday, Wednesday, and Friday) for the test duration. ORP will be recorded daily from day zero of the seven day equilibration period through the end of the 28-day experiment period, and prior to each renewal. The overlying water may be gently aerated, if necessary, to maintain dissolved oxygen levels at ≥ 4.0 mg/L.

7. FINAL REPORT

The final report is prepared to contain, at a minimum, the following information:

- Objectives and procedures stated in the approved protocol, including any changes

made to the original protocol

- Identity of the test article(s) by name or code number and a description of any pretreatment
- Source of the overlying water, its chemical characteristics, and a description of any pretreatment
- ORP measurements of sediment/porewater from test chambers
- Any unforeseen circumstances that may have affected the quality or integrity of the study
- Signature of the project manager, senior technical reviewer, and quality control officer authorizing release of the report
- Location of all archived data and the original copy of the final report at EA

Items of data to be included in the report consist of experimental design and test performance, and tabular presentation of ORP.

8. QUALITY ASSURANCE

8.1 Amendments to Protocol

Amendments to the authorized protocol established by EA or by the client are made only after proper authorization. Such authorization is achieved by completion of the Protocol Amendment Form by EA after consultation with the client.

8.2 Standard Operating Procedures

Unless otherwise specified, all procedures given in the protocol are subject to detailed Standard Operating Procedures (SOPs) which are contained in the SOP manuals of the participating departments. These SOPs and protocols generally follow the type of requirements in the US EPA's Good Laboratory Practice Standards (GLPs) (US EPA 1989). Additionally, ORP monitoring procedures will follow the requirements in the US EPA's Region 4, Science and Ecosystem Support Division Field Measurement of Oxidation-Reduction Potential Operating Procedure number SESDPROC-113-R1 (US EPA 2013).

8.3 Quality Assurance Evaluation

Studies conducted under this protocol may be subject to internal audit by EA's Quality Assurance Unit. A quality control officer is responsible for monitoring each study to assure the

client that the facilities, equipment, personnel, methods, practices, records, and controls are in conformance with EA's QC program and, if applicable, US EPA's GLPs.

8.4 Inspection by Regulatory Authorities

In the event of an inspection of EA by an outside authority during the course of the study, the client whose study is being inspected will be consulted before examiners are permitted access to any of the project records or the experimental areas.

8.5 Archives

Copies of project-specific records shall be transferred to the client promptly after the project is completed or as negotiated and budgeted. Original primary data are retained at EA for 5 years. Primary data include chain-of-custody records, laboratory data sheets, records, memoranda, notes, photographs, microfilm, and computer printouts that are a result of the original observations and activities of the study and which are necessary for the reconstruction and evaluation of the study report.

8.6 Location

Studies are conducted at the Ecotoxicology Laboratory of EA Engineering, Science, and Technology, Inc. in Hunt Valley, Maryland.

9. HEALTH AND SAFETY

9.1 Safety

All laboratory staff members are required to read EA's laboratory safety manual (EA 2012 or most recent version) prior to working in the laboratory. The safety manual includes general safety rules to be followed in the laboratory, procedures for cleaning up spills and reporting accidents, the location and use of safety equipment, and the safe handling and storage of chemicals. A copy of the safety manual is located in the testing laboratory.

9.2 Pollution Prevention and Waste Management

Wastes generated by the laboratory during toxicity testing must be properly handled and disposed of in accordance with the laboratory safety manual and applicable local, state, and federal regulations. Procedures for water disposal is detailed in the laboratory Quality Assurance and Standard Operating Procedures Manual.

11. Test Specifications

Aeration:	Gentle aeration may be provided through a 1-ml glass pipet, placed no closer than 2 cm above the sediment surface
Temperature:	20±1°C
Light Quality:	Wide-spectrum fluorescent light
Light Intensity:	50-100 f.c.
Photoperiod:	16-hour light, 8-hour dark
Overlying Water:	Synthetic seawater or appropriate receiving water
Test Container:	1-L beakers
Test Volume:	100-200 ml of sediment with 400-800 ml of overlying water (typically 1:4 ratio of sediment to overlying water)

Number of Test Chambers:	5 (sediment selected from each of 5 stations)
Renewal of Overlying Water:	3 times/week (e.g., Monday, Wednesday, and Friday)
Test Duration:	35 days (7 day equilibration plus 28-day test)
Monitoring Frequency:	Once per day
Corrective Actions:	None

ATTACHMENT A
Data Assessment

I.0 Introduction

This method was developed by the Engineering and Analysis division within the USEPA's Office of Science and Technology. The method is used for isomer specific determination to detect the Tetra- through octa- chlorinated dibenzo-p-dioxins and dibenzofurans associated with the Clean Water Act (CWA, as amended 1987); the Resource Conservation and Recovery Act (RCRA, as amended 1986); the Comprehensive Environmental Response, the Compensation and Liability Act (as amended in 1986); and the Safe Drinking Water Act and other dioxin and furan compounds amenable to this method.

The dioxins and furans may be determined in water, soil, sediment, sludge, tissue, and other matrices using this method. The method is based on EPA, industry, and academic methods.

2.0 Applicability

The attached Standard Operating Procedure (SOP) is applicable to chlorinated dibenzodioxin and chlorinated dibenzofuran (CDD/CDF) data obtained using EPA Method 1613B, Polychlorinated Dibenzodioxins (CDDs) and Polychlorinated Dibenzofurans (PCDFs) by Isotope Dilution using High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry (HRGC/HRMS), October 1994. Its scope is to facilitate the data validation process of the data reported by the contracting laboratory and to ensure that the data is being reviewed in a uniform manner. This SOP is based upon the quality control and quality assurance requirements specified in Method 1613B, October 1994.

3.0 Responsibilities/Scope

- 3.1 The reviewer must be knowledgeable of the analytical method and its QC Criteria.
- 3.2 The reviewer must complete the following:
- 3.2.1 Data Assessment Checklist - The data reviewer must read each item carefully and must check yes if there is compliance, no if there is non compliance and N/A if the question is not applicable to the data.
- 3.2.2 Data Assessment Narrative - The data reviewer must present professional judgement and must express concerns and comments on the validity of the overall data package. The reviewer must explain the reasons for rejecting and/or qualifying the data. Example of Data Assessment format is provided in Attachment A.
- 3.2.3 Communication Record Log - All communication must be in writing, and it must be documented on the Communication Record Log Sheet. A photocopy of the Communication Record Log is attached to the Data Assessment package.
- 3.2.4 Paperwork - Upon completion of the review the following are to be maintained with the data package and returned to the authorized person :
- a. completed data assessment checklist and narrative (original)
 - b. Two copies of the data assessment narrative
 - c. Communication record Log (original and copy)
- 3.3 Rejection of Data - All values determined to be unacceptable on the Dioxin/Furan Analysis Data Sheet (Form I) must be flagged with an "R". The qualifier R means that due to significant QA/QC problems the analysis is invalid and it provides no information as to whether the compound is present or not. Once the data are flagged with R any further review or consideration is unnecessary. The qualifier "J" is used to indicate that due to QA/QC problems the results are considered to be estimated. The qualifier "NJ" indicates that there is presumptive evidence for the presence of the compound at an estimated value.

The data reviewer must explain in the data assessment narrative why the data was qualified. He or she must also indicate all items of contract non-compliance. When 2,3,7,8- substituted TCDD, TCDF, PeCDD and PeCDF data are rejected (flagged "R") or qualified "J" the project office must be notified promptly. If holding times have not been exceeded reanalysis of the affected samples may be requested. All qualifications and corrections on the Analysis Data Sheet must be made in red pencil.

4.0 Definitions

CALIBRATION SOLUTION: solutions containing known amounts of selected analytes, internal standards and recovery standards that are analyzed prior to sample analysis. The solutions are used to determine the ratio of the instrument response of the analytes to that of the appropriate internal standard and the internal standards to that of the recovery standards.

CALIBRATION VERIFICATION (VER): a mixture of known amounts of analytes that is analyzed every 12 hours to demonstrate continued acceptable GC/MS performance and establish the retention time window for each homologue.

CDD: Chlorinated Dibenzo-p-Dioxin. The isomers and congeners of tetra- through octa-chlorodibenzo-p-dioxin.

CDF: Chlorinated Dibenzofuran. The isomers and congeners of tetra- through octa-chlorodibenzofurans.

CLEAN-UP STANDARD: only one labeled analyte (2,3,7,8-TCDD) is added to all samples extracts prior to any Clean-up procedure. This standard is used to differentiate between losses of analytes or internal standards during extraction and losses that occur during the various Clean-up procedures.

CONGENER: elements of the same group in the periodic table.

DEFLECTIONS: bend or broadening of a peak

ESTIMATED DETECTION LIMIT (EDL): the concentration of a analyte required to produce a signal with peak height of at least 2.5 times the background signal level. The EDL is calculated for each 2,3,7,8 substituted isomer for which the response of the quantitation and confirmation ions is less than 2.5 times the background level.

ESTIMATED MAXIMUM POSSIBLE CONCENTRATION (EMPC): the concentration of a given analyte that would produce a signal with a given area peak. The EMPC is calculated for each 2,3,7,8 substituted isomer for which the response of the quantitation and/or confirmation ions has signal to noise in excess of 2.5 times the background level but does not meet identification criteria.

Field Blank: An aliquot of reagent water or other reference matrix that is placed in a sample container in the laboratory or the field, and treated as a sample in all respects, including exposure to sampling site conditions, storage, preservation, and all analytical procedures. The purpose of the field blank is to determine if the field or sample transporting procedures and environments have contaminated the sample.

FIELD CHAIN OF CUSTODY: see Traffic Report

GC: Gas chromatograph or gas chromatography.

GEL PERMEATION CHROMATOGRAPHY (GPC): removes many high molecular weight interferences that cause GC column performance to degrade. It may be used for all soil and sediment extracts and may be used for water extracts that are expected to contain high molecular weight organic compounds.

HOMOLOGUE: a member or members of a particular homologous series that has the same molecular weight but not necessarily the same structural arrangement. For example, the 28 pentachlorinated dibenzofurans are homologues.

HPLC: high performance liquid chromatography

HRGC/HRMS: high resolution gas chromatography/ high resolution mass spectrometry.

INITIAL CALIBRATION STANDARD SOLUTION (CS1-CS5): analysis of analytical standards for a series of different specified concentrations. The initial calibration is used to define the linearity and dynamic range of the response of the mass

spectrometer to the target compounds.

INITIAL PRECISION AND RECOVERY (IPR): must be performed by the laboratory to establish the ability to generate acceptable precision and accuracy by analyzing four aliquots of the diluted PAR standard. The standard deviation (s) of the concentration and the average concentration (x) for each unlabeled analyte must be within range established by the Method (Table 6). An IPR is performed prior to the first time this method is used and any time the method or instrumentation is modified.

INTEGRATED ION CURRENT: electronic output to computer from instrument to provide a hard copy of area and height of a peak that may or may not be an analyte of interest.

INTERNAL STANDARDS (IS): labeled analytes are added to every sample and are present at the same concentration in every blank, quality control sample, and calibration solution. The IS are added to the sample before extraction and are used to measure the concentration of the analytes. In Method 1613B, the ISs are ¹³C₁₂-1,2,3,4-TCDD and ¹³C₁₂-1,2,3,7,8,9-HxCDD.

ION ABUNDANCE RATIO: mathematical comparison of selected pair of ions stipulated by the method for each target analyte. The ratio between each pair of ions must fall within established limits. These ions are needed for the identification and quantitation of target analytes.

ISOMER: chemical compounds that contain the same number of atoms of the same elements, but differ in structural arrangement and properties. For example 1,2,3,4-TCDD and 2,3,7,8-TCDD are structural isomers.

LABELED ANALYTE (or analog): an analyte that has isotopically carbon added to its chemical structure. These compounds are used to establish identification (retention time) and used for quantitation of unlabeled analytes.

MASS/CHARGE: usually expressed as m/z.

METHOD BLANK (MB): an analytical control consisting of all reagents, internal standards and surrogate standards that is carried through the entire analytical procedure. The MB is used to define the level of laboratory background contamination.

Minimum Level (ML): The level at which the entire analytical system must give a recognizable signal and acceptable calibration point to the analyte. It is equivalent to the concentration of the lowest calibration standard, assuming that all method-specified sample weights, volumes, and clean up procedures have been employed.

MAXIMUM CONCENTRATION LEVEL (MCL): Highest level of concentration for each analyte depending upon upper concentration of analyte. Usually used to determine upper level of the concentration range.

NON-CONGENER: elements not from the same group in the periodic table.

NON-2,3,7,8 SUBSTITUTED ANALYTES: analytes whose structure have positions other than 2,3,7,8.

ONGOING PRECISION AND RECOVERY (OPR): must be performed by the laboratory to establish the ability to maintain on a continuous basis, acceptable precision and accuracy. The standard deviation (s) of the concentration and the average concentration (x) for each unlabeled analyte must be within range established by the Method (Table 6).

PAR: Precision and Recovery standard. Secondary standard that is diluted and spiked to form IPR and OPR. The standard deviation (s) of the concentration and the average concentration (x) for each unlabeled analyte must be within range established by the Method (Table 6).

PERCENT MOISTURE: an approximation of the amount of water in a soil/sediment sample made by drying an aliquot of the sample at 105°C. The percent moisture determined in this manner also includes contributions from all compounds that may volatilize at this degree including water. %M is determined from decanted samples and from samples that are not decanted.

PERCENT VALLEY: see Resolution

PERFLUOROKEROSENE (PFK): compound used to establish mass spectral instrument performance for dioxin/furan analysis.

PERFORMANCE EVALUATION MIXTURE (PEM): See Performance Evaluation (PE) Sample,

PERFORMANCE EVALUATION (PE) SAMPLE: a chemical waste, soil or water sample containing known amounts of unlabeled CDDs/PCDFs used for Quality Assurance programs. There are 3 types of PE's available. PEM Blank which consists of uncontaminated soil and used to monitor possible crossover contamination of samples in the field and laboratory. PEM Interference Fortified Blank which is a soil containing matrix interference and spiked by the laboratory with target compounds. A PEM sample(s) is a soil sample containing known amounts of unlabeled TCDD or a mixture of TCDD and other PCDD/PCDF isomers. These PEMs are used to monitor the laboratory's performance.

PCDPE: Polychlorinated Diphenylether: isomers having the same SICP and ion ratios identical to furan isomers and are monitored for interference in furan qualitative and quantitative analysis.

Quality Control Check Sample (QCS): A sample containing all or a subset of the analytes at known concentrations. The QCS is obtained from a source external to the laboratory or is prepared from a source of standards different from the source of calibration standards. It is used to check laboratory performance with test materials prepared external to the normal preparation process.

RECOVERY: a determination of the accuracy of the analytical procedure made by comparing measured values from a fortified (spiked) sample against the known spiked values. Recovery is determined by the following equation:

$$\% \text{ Recovery} = \frac{\text{measured value}}{\text{known value}} \times 100\%$$

RELATIVE RETENTION TIME (RRT): ratio of the retention time of the analyte versus the retention time of the corresponding internal standard. RRT for each analyte must be within range established by the method.

RELATIVE RESPONSE (RR): the ratio of the area response of the mass spectrometer to a known amount of an analyte (unlabeled to labeled) versus a known concentration in standard solution, plotted using linear regression. The RR is used to determine instrument performance and is used in the quantitation calculations. RR are calculated using the following equation:

$$RR = \frac{(A_n^1 + A_n^2) C_l}{(A_l^1 + A_l^2) C_n}$$

$A_n^1 + A_n^2$ are the areas of the primary and secondary m/z's for the unlabeled compound.

$A_l^1 + A_l^2$ are the areas of the primary and secondary m/z's for the labeled compound.

C_l is the concentration of the labeled compound in the calibration standard.

C_n is the concentration of the unlabeled compound in the calibration standard.

Relative Standard Deviation (RSD): The standard deviation times 100 divided by the mean. Also termed "coefficient of variation".

RESPONSE FACTOR (RF): the ratio of the response of the mass spectrometer to a known amount of an analyte relative to that of a known amount of internal standard as measured in the initial and continuing calibrations. The RF is used to determine instrument performance using correlation coefficient and is used in the quantitation calculations. RF are calculated using the following equation:

$$RF = \frac{(A_s^1 + A_s^2) C_{is}}{(A_{is}^1 + A_{is}^2) C_s}$$

$A_s^1 + A_s^2$ are the areas of the primary and secondary m/z's for the compound to be calibrated.

$A_{is}^1 + A_{is}^2$ are the areas of the primary and secondary m/z's for the internal standard.

C_s is the concentration of the compound in the calibration standard.

C_{is} is the concentration of the internal standard.

RESOLUTION: the separation between peaks on a chromatogram. Resolution is calculated by dividing the height of the valley between the peaks by the peak height of the smaller peak being resolved, multiplied by 100.

RINSATE: a portion of the solvent that is used to rinse sampling equipment. The rinsate is later analyzed to demonstrate that samples were not contaminated during collection.

SAMPLE DELIVERY GROUP (SDG): a unit within a single case that is used to identify a group of samples for delivery. A SDG is a group of 20 or fewer samples within a case, received over a period of time up to 14 calendar days. Data from all samples in a SDG are due concurrently. A SDG is defined by one of the following, whichever occurs first:

- Case; or
- each 20 samples within a case; or
- each 14 day calendar period during which samples in a case are received, beginning with receipt of the first sample in the case or SDG.

SELECTED ION MONITORING (SIM): a mass spectrometric technique whereby ions with predetermined mass/charge ratios (m/z) are monitored, as opposed to scanning MS procedures in which all m/z's between two limits are monitored.

SICP: A plot of ion abundance versus time for each ion which provides the retention time, peak area and height. This information is used for identification and quantitation of target analyte.

SIGNAL TO NOISE (S/N) RATIO: the ratio of analyte signal to random background signal. To determine the ratio, display each characteristic ion using a window 100 scans wide, and draw a base line from the lowest point in the 100 scan window. The noise is defined as the height of the largest signal (excluding signal due to CDDs/PCDFs or other chemicals) within the 100 scan window. The signal is defined as the height of the PCDD/ PCDF peak. If the data system determines the ratio, the Contractor shall demonstrate comparability between the above criteria and the automated S/N determination. Chemical noise is left to the judgement of the analyst.

2,3,7,8 SUBSTITUTED ANALYTES: analytes whose structure has other positions as well as the 2,3,7,8 positions.

TOXICITY EQUIVALENCY FACTOR (TEF): a method of converting concentrations of CDDs/PCDFs to an equivalent concentration of 2,3,7,8-TCDD to obtain an estimation of the toxicity of the entire sample. The concentrations can be found on Form I PCDD-2 in the DFLM01.1 Statement of Work for Dioxin Analysis.

TRAFFIC REPORT (TR): (may also be called Field Chain of Custody), a sample identification form filled out by the sampler, which accompanies the sample during shipment to the laboratory and documents sample condition and receipt by the laboratory.

TWELVE HOUR TIME PERIOD: the 12 hour time period begins with the injection of the CS3 solution on the DB-5 (or equivalent) column or the injection of the column performance solution on the SP-2331 (or equivalent) column. The 12 hour period continues until 12:00 hours have elapsed according to the system clock. To be included in a given 12-hour time period,

a sample or standard must be injected with 12:00 hours of the CS3 solution or the column performance solution.

UNLABEL ANALYTE: target compound that has not been isotopically altered.

VALIDATED TIME OF SAMPLE RECEIPT (VTSR): the date on which a sample is received at the Contractor's facility, as recorded on the shipper's delivery receipt and sample traffic report.

WINDOW DEFINING MIXTURE (WDM): a mixture containing the first and last eluting isomer for each congener. The retention time for each first and last eluting isomer establishes the retention time window for each congener. All analytes in the standards (calibrations, internal standards, recovery standards, Clean-up standard) and identified analytes in samples must have a reported retention time within the established window. It is analyzed before any calibration standard, at the beginning of each 12 hour time period or when there is a shift greater than 10 seconds between retention time of recovery standards in standards or any analysis from retention time in recent calibration verification.

YES NO N/A

PACKAGE COMPLETENESS AND DELIVERABLES

CASE NUMBER: _____ LAB: _____
SITE: _____

I.0 Data Completeness and Deliverables

- | | | | | |
|-----|---|-----|-----|----|
| 1.1 | Does the Traffic Report or Field Chain of Custody list all samples? | [] | __ | __ |
| 1.2 | Is the Case Narrative present? | [] | __ | __ |
| 1.3 | Are the Case Number and SDG numbers contained in the case narrative? | [] | __ | __ |
| 1.4 | Do the Traffic Reports, Field Chain of Custody or Lab Case Narrative indicate problems with sample receipt, sample condition, analytical problems, or other comments affecting the quality of the data? | __ | [] | __ |

ACTION: Use professional judgement to evaluate the effect of the noted problems on the quality of the data.

ACTION: As per region II requirements, if any sample analyzed as a soil, contains 50% to 90% water, all data shall be flagged as estimated "J". If a soil sample Contains more than 90% water, then qualify positive hits "J", and non detects "UJ".

ACTION: If sample cooler temperature was greater than 10 C, then flag all positive hits "J" And non detects "UJ".

2.0 Reporting Requirements and Deliverables

2.1 All deliverables must be clearly labeled with the Case number and the associated sample/traffic number. Missing or illegible or incorrectly labeled items must be identified. The Project Officer must immediately be contacted and requested to ask laboratory to submit the missing or incorrect items.

2.2 The following forms were taken from the CLP SOW, DFLM01.1 and should be specified in the Project Plan. Laboratories will not always use the exact CLP format for the forms. A comparison of CLP forms must be made against the Laboratory's version. Some information may not be found on the exact form as the CLP version but may be located on another form. As long as the information is present and accessible, it is not a problem. Are these forms (CLP or lab's version) present?

ACTION:	If deliverables are missing, contact the Project Officer to request explanation/resubmittals or obtain written permission to contact the lab for explanation/resubmittal. If the lab cannot provide missing deliverables, assess the			

YES NO N/A

effect on the validity of the data. Note in the Data Assessment.

2.5 Was the sample data package paginated and one sided?

ACTION: If no, document difficulties of reviewing data caused by lack of pagination in Data Assessment.

3.0 Holding Times

3.1 Have samples been analyzed within proper holding times?

a. For aqueous samples, 30 days from VTSR to extraction?

b. For soil/sediment samples, 30 days from VTSR to extraction?

c. For fish and tissue samples, one (1) year from VTSR to extraction?

d. For all samples 45 days from time of extraction to time of analysis?

ACTION: If holding times are exceeded, flag all positive hits as estimated ("J"), and non-detects as estimated "UJ". Holding time criteria do not apply to PE samples. If holding times are grossly exceeded (e.g. by greater than two times the specified Technical holding times), either on the first analysis or upon reanalysis, flag positive hits as estimated "J", and flag non-detects as unusable "R".

Note: The data reviewer must note whether or not technical and contractual holding times were met.

4.0 Instrument Performance

4.1 Mass Calibration - Mass calibration of the MS must be performed prior to analyzing calibration solutions, blanks, samples, and QC samples. A static resolving power of at least 10,000 (10% valley definition) must be demonstrated at appropriate masses before any analysis is performed. Static resolving power checks must be performed at the beginning and at the end of each 12 hour period of operation. Include in the narrative, minimum required resolving power of 10000 was obtained for perfluorokerosene (PFK) ion 380.9760. This is done by first measuring peak width at 5% of the maximum. This should not exceed 100 ppm, i.e., it should not exceed 0.038, for ion 380.9760. Resolving power, then is calculated using the formula,

$$\text{Resolving Power} = m/\Delta m = 380.9760/0.038 = 10025.$$

NOTE: The mass calibration is generally not reported. Improper mass calibration may be detected by examining ion abundance ratios for initial and continuing calibration standards. If the mass calibration is not properly performed, the standards will not have ion abundance ratios within criteria.

4.2 Window Defining Solution/ Isomer Specificity Test Standards

The Window Defining Solution must contain the first and the last isomers of each homologue CDD/CDF, (the labeled and internal standards are optional). The solution also should contain a series of other TCDD analytes for the purpose of documenting the chromatographic resolution.

4.2.1 For analyses on a DB-5 (or equivalent) GC column, the chromatographic resolution is evaluated by the analysis of Isomer Specificity Test Standards at the beginning of every 12 hour period. Was this performed accordingly?

YES NO N/A

ACTION: If the Isomer Specificity Test Standard was not analyzed at the required frequency, use professional judgement to determine the effect on the quality of the data. Document in Data Assessment under contract non-compliance.

4.2.2 Were all peaks labeled and identified on the Selected Ion Current Profiles (SICPs)?

4.2.3 Did the absolute retention time of the internal standards ¹³C₁₂-1,2,3,4-TCDD exceed 25.0 minutes on the DB-5 column and 15.0 minutes on the DB-225 column? (Method 1613B, Section 10.2.4)

4.2.4 Are the relative retention times of native and labeled CDD's and CDF's within the limits given in Table 2 of the method. (Method 1613B, Section 15.4.1.2)

ACTION: If no for sections 4.2.2, 4.2.3 and 4.2.4, assess the effect on the validity of the data. Note in the Data Assessment.

4.2.5 For DB-5 or equivalent, (Method 1613B, Section 15.4.2.2) the peak separation between the unlabeled 2,3,7,8-TCDD and the peaks representing any other TCDD analyte shall be resolved with a valley of ≤ 25 percent. Was this criteria met?

$$\% \text{ Valley} = (x/y) \times (100)$$

Y = The peak height of 2,3,7,8-TCDD analyte

X = The distance from the baseline to the bottom of the valley between the adjacent peaks.

ACTION: If the percent valley criteria are not met, qualify all positive data "J". Do not qualify non-detects.

4.2.6 Is the last eluting tetra chlorinated congener (1,2,8,9-TCDD) and the first eluting penta chlorinated congener (1,3,4,6,8-PeCDF) separated properly, since they elute within 15 seconds of each other?

ACTION: If one of the congener is missing, report that in the Data Assessment.

5.0 Initial 5-Point Calibration

The initial calibration standard solutions (CS1-CS5) must be analyzed prior to any sample analysis. However, initial calibration should be analyzed when the CS3 Calibration Verification (VER) or Isomer Specificity Test Standard do not meet performance criteria. The initial calibration standards must be analyzed on the same instrument using the same GC/MS conditions that were used to analyze the Window Defining **Solution** and the Isomer Specificity Test Standards.

Was the initial calibration performed at the frequency specified above?

5.1 The method allows the Laboratory to perform quantitative analysis by isotope dilution and internal standard, or to combine calibration solutions.

1. Isotope Dilution: performed for the fifteen 2,3,7,8-substituted CDDs and CDFs unlabeled analytes with labeled analytes added to the samples prior to extraction and for 1,2,3,7,8,9-HXCDD and OCDF (see sections 5.2.8 and 5.2.9). The relative response (RR) is calculated and the percent coefficient of variation must be ≤ 20% over the 5 point range (1613B sec. 10.5.4) to use the average relative response for quantitation, otherwise a calibration curve

YES NO N/A

must be used..

2. Calibration by Internal Standard: performed for non-2,3,7,8 substituted compounds having no labeled analytes in this method and for measurement of labeled compounds for intra laboratory statistics.. The response factor (RF) is calculated and the percent coefficient of variation must be $\leq 35\%$ over the 5 point range (1613B sec. 10.6.3) to use the average response factor for quantitation, otherwise a calibration curve must be used.
 3. Combined Calibration: performed by using solutions containing unlabeled, labeled compounds and internal standards. The requirements of each of the above methods are used. This method allows the laboratory to produce a single set of curves for isotope dilution and internal standard method.
- 5.1.1 The following MS/DS conditions must be used:
- 5.1.1.1 Mass calibration as per Section 4.1?
- 5.1.1.2 Were SIM data acquired for each of the ions listed in Table 8, including interfering ions? (see analytical method)
- 5.2 Were the following GC criteria met?
- 5.2.1 The chromatographic resolution between the 2,3,7,8-TCDD and the peaks representing any other unlabeled TCDD isomers must be resolved with a valley of ≤ 25 percent on the primary analysis (DB-5) column (1613B sec. 15.4.2.2).
- 5.2.2 The chromatographic resolution between the 2,3,7,8-TCDF and the peaks representing any other unlabeled TCDF isomers must be resolved with a valley of ≤ 25 percent on the confirmation (DB-225 or SP2330) analysis column.
- 5.2.3 For all calibration solutions, the relative retention time of peaks representing an unlabeled 2,3,7,8- substituted CDD or CDF must be within the limits given in table 2 of the Method. The retention times of the peaks representing non-2,3,7,8- substituted CDD or CDF's must fall within the retention time windows established by the Window Defining Solution. In addition, the absolute retention times of internal standards, $^{13}\text{C}_{12}$ 1,2,3,4-TCDD and $^{13}\text{C}_{12}$ 1,2,3,7,8,9-HxCDD shall not change by more than 15 seconds between the CS3 analysis and the analysis of any other standard.
- 5.2.4 Are the two SIM ions for each homolog must maximize simultaneously and within 2 seconds of the corresponding labeled analyte ions?(1613B sec. 16.1)
- 5.2.5 The relative ion abundance criteria for CDDs/CDFs listed in Table 9 (see analytical method) must be met.
- 5.2.6 For all calibration solutions the signal to noise ratio (S/N) for the GC signal present in every SICP, including the ones for the labeled standards must be ≥ 10 .
- 5.2.7 The percent relative standard deviations (% RSD) for the mean response factors (RRF) from the 17 unlabeled standards must be $\leq 20\%$, and those for the 15 labeled reference compounds must be $\leq 35\%$.
- 5.2.8 Labeled analyte 1,2,3,7,8,9-HxCDD is used as an internal standard in this method, and can not be used to quantitate corresponding unlabeled analyte. The unlabeled 1,2,3,7,8,9-HxCDD must be

YES NO N/A

quantitated using the average of the responses of the labeled analytes of 1,2,3,4,7,8-HxCDD and 1,2,3,6,7,8-HxCDD. The concentration of the unlabeled 1,2,3,7,8,9-HxCDD is corrected for the average recovery of the other HxCDD's. Was the unlabeled 1,2,3,7,8,9-HxCDD quantitated correctly? _____

5.2.9 The labeled analog of OCDF is not added to the sample because of a potential interference. Unlabeled OCDF is quantitated against the labeled OCDD. The concentration of the unlabeled OCDF is corrected for the recovery of the labeled OCDD. Was the unlabeled OCDF correctly quantitated against the labeled OCDD. _____

ACTION:

1. If mass calibration criteria as specified in Section 4.1 was not met, note in Data Assessment.
 2. If the selected monitoring ions specified in Table 8 were not used for data acquisition, the lab must be contacted by the Project Officer for an explanation. If an incorrect ion was used, reject "R" all the associated data.
 3. If the 25% percent valley for TCDD requirement was not met, quality positive data "J". Do not qualify non-detects. The tetra and penta (dioxins and furans) are affected. Heptas, Hexas and Octas are not affected.
 4. If the ion abundance ratio for an analyte is outside the limits, flag the results for that analyte "R" (reject).
 5. If the ion abundance ratio for an internal or labeled standard falls outside the QC limits flag the associated positive hits with "J". No effect on the non-detects.
 6. If the signal to noise ratio (S/N) is below control limits, use professional judgement to determine quality of the data.
 7. If the %RSD for each unlabeled analyte exceeds 20%, or the %RSD for each labeled analyte exceeds 35%, flag the associated sample positive results for that specific analyte as estimated ("J"). No effect on the non-detect data.
 8. If 1,2,3,7,8,9-HxCDD was not calculated using the correct HxCDD response (average) factor either manually recalculate the values for all standards and samples or contact Project Officer to request resubmittals from the laboratory.
 9. If OCDF was not calculated using the correct response factor (OCDD), either manually recalculate the values for all standards and data or contact Project Officer to request resubmittals from the laboratory.
 10. Non compliance of any other criteria specified above should be evaluated using professional judgement.
- 5.2.10 Spot check response factor calculations and ion ratios. Ensure that the correct quantitation ions for the unlabeled CDDs/CDFs and labeled standards were used. In addition, verify that the appropriate labeled standard was used for each analyte.

To recalculate the response factor, use the equation:
For target compounds (unlabeled analytes with corresponding labeled analytes):

$$RR = \frac{(A_{n1} + A_{n2}) \times Q_i}{A_i}$$

YES NO N/A

$$(A_{I1} + A_{I2}) \times Q_n$$

For labeled analytes, Internal standards and cleanup standard listed in Table 6 of method 1613:

$$RF = \frac{(A_{I1} + A_{I2}) \times Q_{is}}{(A_{is1} + A_{is2}) \times Q_I}$$

Note: There is only one m/z for ³⁷Cl₄2,3,7,8-TCDD.

A_{n1} + A_{n2} = integrated areas of the two quantitation ions of analytes of interest. (Target analyte, unlabeled compounds)

A_{I1} + A_{I2} = integrated areas of the two quantitation ions of the appropriate labeled analytes compound.

A_{is1} + A_{is2} = integrated areas of the two quantitation ions of the appropriate internal standard.

Q_n = quantity of the unlabeled PCDD/PCDF analyte injected [pg]

Q_I = quantity of the appropriate labeled analytes compound [pg]

Q_{is} = quantity of the appropriate internal standard injected [pg]

ACTION: If calculations were not performed correctly, notify the Project Officer to initiate resubmittals from the laboratory.

6.0 System and Laboratory Performance (Calibration Verification and Isomer Specificity Test Standard)

At the beginning of a 12 hour shift during which analyses are performed, GC/MS system performance and calibration are verified for all unlabeled and labeled compounds. For these tests the calibration verification (VER) standard and the isomer specificity test standards shall be used to verify all performance criteria.

Only if the laboratory meets all performance criteria may samples, blanks, and precision and recovery standards be analyzed.

6.1 Calibration Verification

6.1.1 Was the relative ion abundance for CDDs/CDFs listed in Table 9 of the analytical method met? (Method 1613B, Section 15.3.2)

6.1.2 Were the peaks representing each unlabeled and labeled compound in the verification standard present with signal to noise ratio (S/N) of ≥ 10? (Method 1613B, Section 15.3.3)

6.1.3 For each compound, was the concentration within the limit in Table 6 of the method? (Method 1613B, Section 15.3.5)

6.1.4 Were the absolute retention time of the internal standards ¹³C₁₂-1,2,3,4- TCDD and ¹³C₁₂1,2,3,7,8,9- HxCDD within ± 15 seconds of the retention times obtained during calibration? (Method 1613B, Section 15.4.1.1)

6.1.5 Were the relative retention times of the unlabeled and labeled CDDs and CDFs within the limits given by Table 2 of the method? (Method 1613B, Section 15.4.2.2)

YES NO N/A

6.2 Isomer Specificity Test Standard

- 6.2.1 Was the chromatographic resolution between 2,3,7,8-TCDD and the peaks representing any other unlabeled TCDD isomers resolved with a valley of ≤ 25 percent on the primary analysis (DB-5) column? (Method 1613B, Section 15.4.2.2)
- 6.2 Was the chromatographic resolution between 2,3,7,8-TCDF and the peaks representing any other unlabeled TCDF isomers resolved with a valley of ≤ 25 percent on the confirmation (DB-225 or SP2330) analysis.

ACTION:

1. If the ion abundance ratio for an analyte is outside the limits, flag the results for that analyte "R" (reject).
 2. If the signal noise ratio (S/N) is below control limits, use professional judgement to determine the quality of the data.
 3. If an analyte concentration fell outside the acceptance criteria listed in Table 6 of the method.
 - A. If the acceptance criteria for each unlabeled analyte and/or for each labeled analyte exceeds the range, flag the associated sample positive results for that specific analyte as estimated ("J"). No effect on the non-detect data.
 - B. If the acceptance criteria for each unlabeled analyte and/or for each labeled analyte is below the range, flag the associated sample positive results as well as non-detects for that specific analyte as estimated ("J").
 - C. If the acceptance criteria for each unlabeled analyte and/or for each labeled analyte is excessively below, $\leq 10\%$ of the range, at the minimum, flag the associated sample positive results as well as non-detects for that specific analyte as estimated ("J"). However the validator may use professional judgement to accept or reject positive data and non-detects.
 4. If the 25 percent valley for TCDD and TCDF requirement was not met, qualify positive data "J". Do not qualify non-detects. The tetras and pentas (dioxin and furans) are affected. Heptas, Hexas and Octas are not affected.
 5. Non compliance of any other criteria specified above, in the method should be evaluated using professional judgement.
- 6.3 Spot check response factor calculations and ion ratios. Ensure that the correct quantitation ions for the unlabeled CDDs/CDFs and labeled standards were used. In addition, verify the appropriate labeled standard was used for each analyte.

7.0 Sample Data

NOTE: Any qualifications such as "J" applied to target compounds should be also applied to their associated total congeners concentration column.

- 7.1 Were the following MS/DS conditions used?
- 7.1.1 SIM data were acquired for each of the ions listed in Table 8 (see analytical method)

	YES	NO	N/A
including diphenylether interfering ions.	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2 Were the following identification criteria met?			
7.2.1 For the 2,3,7,8 substituted analytes found present and the corresponding labeled compound or internal standard in the sample extract, must show relative retention times at the peak height within the limits given in Table 2. (Method 1613B, Section 16.4)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2.2 For non-2,3,7,8 substituted compounds (tetra through octa) found present, the retention time must be within the window established by the Window Defining Solution, for the corresponding homologue (Method 1613B, Section 16.4)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2.3 All specified ions listed in Table 8 for each isomer found present and the associated labeled compounds must be present in the SICP. The two SIM ions for the analyte, the labeled compound, and the internal standard must maximize simultaneously.(± 2 sec.) (Method 1613B, Section 16.1)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2.4 The integrated ion current for each characteristic ion of the analyte identified as positive, must be at least 2.5 times background noise and must not have saturated the detector. (Method 1613B, Section 16.2)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2.5 The integrated ion current for the labeled compounds, internal standards, and cleanup standard characteristic ions must be at least 10 times background noise. (Method 1613B, Section 16.2)	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2.6 The relative ion abundance criteria for all CDDs/CDFs found present must be within the limits of Table 9, or 10% of the ratio in the midpoint CS3 calibration or calibration verification (VER) whichever is most recent.	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2.7 The relative retention time of the unlabeled 2,3,7,8-substituted PCDD or PCDF must be within the limits given in Table 2 (Method 1613B, Section 16.4).	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2.8 The relative ion abundance criteria for the labeled compounds, cleanup, and internal standard must be met (Table 9 - Method 1613B).	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
7.2.9 The analyte concentration must be within the calibration range. If not, dilution should have been made to bring the concentration within the calibration range. Was this criterion met?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
NOTE: The analytical method clearly states that samples containing analytes having concentrations higher than 10 times the upper MCLs should be analyzed using a less sensitive, high resolution GC/low resolution MS method.			
7.2.10 The identification of a GC peak as a PCDF can only be made if no signal having a S/N ≥ 2.5 is detected at the same time in the corresponding polychlorinated diphenylether (PCDPE) channel. Was the above condition met?	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

- ACTION:
1. If the selected monitoring ions specified in Table 3 were not used for data acquisition, the lab must be contacted by the Project Officer for an explanation. If an incorrect ion was used, reject "R" all the associated data.
 2. If the retention time of an analyte falls outside the retention time windows established by the associated Window Defining Mixture take the following action:

YES NO N/A

- A. If the analyte has a corresponding labeled analyte and is within 2 seconds of the labeled analyte, no action taken on positive data or non-detects.
 - B. If the analyte has a corresponding labeled analyte and is outside 2 seconds of the labeled analyte, use professional judgement to determine qualifications for positive data or non-detects. At a minimum, "J" or "JN" positive data.
 - C. If the analyte does not have a corresponding labeled analyte and is outside 2 seconds of the matching unlabeled analyte from the associated calibration, use professional judgement to determine qualifications for positive data or non-detects. At a minimum, "J" or "JN" positive data.
 - D. If analyte meets identification criteria (7.2.2, 7.2.4, 7.2.5, 7.2.7) but does not meet ion abundance ratio criteria (7.2.8) and is not a labeled analog, the sample must be reanalyzed on a confirmation column. If confirmation analysis was not performed, reject "R" the failing analyte.
3. If the criteria listed in section 7.2.4 and 7.2.5 are not met but all other criteria are met, qualify all positive data of the specific analyte with "J".
 4. If the analytes reported positive do not meet criteria for section 7.2.6, reject "R" all positive data for these analytes. Change the positive values to EMPC (Estimated Maximum Possible Concentration). Flag "J"
 5. If the labeled compounds, internal standards and cleanup standards do not meet ion abundance criteria section 7.2.6. and 7.2.7. (Table 8 - analytical method) but they meet all other criteria, flag all corresponding data with "J".
 6. If the lab reported values exceeding the calibration range flag those values with "J".
 7. If peak deflections >50% are visible qualify particular compound with "J".
 8. If PCDF was detected but an interfering PCDFE was also detected (see Section 7.2.9) and concentration not corrected for the interference, cross out the PCDF data. The reported value of PCDF is changed to EMPC.
 9. If the lab did not monitor for PCDFEs, qualify all positive furan data "JN".
- 7.2.10 Spot check calculations for positive data and verify that the same labeled compounds used to calculate RFs were used to calculate concentration and EMPC. Ensure that the proper CDDs/CDFs and labeled compounds were used.

To recalculate the concentration of individual CDD/CDF analytes in the sample use the following equation:

All Matrices other than water

$$C_n \text{ (pg/g)} = \frac{(A_{n1} + A_{n2}) \times Q_i}{W \times (A_{i1} + A_{i2}) \times RR}$$

Water

$$C_n \text{ (pg/L)} = \frac{(A_{n1} + A_{n2}) \times Q_i}{V \times (A_{i1} + A_{i2}) \times RR}$$

YES NO N/A

Where:

$A_{n1} + A_{n2}$ = integrated areas of the two quantitation ions of analyte of interest. (Target analyte)

$A_{i1} + A_{i2}$ = integrated areas of the two quantitation ions of the appropriate labeled analyte compound.

W = Weight (g) of sample extracted

V = Volume (L) of sample extracted

Q_i = Quantity (pg) of the appropriate labeled compound added to the sample prior to extraction.

RR = Calculated relative response from initial calibration. (see section 5.2.10)

ACTION: If the spot check calculations yielded positive hit concentrations with < 15% Difference from those reported in Form I, correct manually. If the difference between the validator's value and the form 1's values are > 15% contact the Project Officer to request from the laboratory for an explanation and a copy of the laboratory's calculations.

7.3 Clean-up procedures

Clean-up may not be necessary for relatively clean samples (drinking waters, ground waters etc). If the matrix required clean-up, the laboratory has 4 different procedures to choose from. Before using any clean-up procedure, the laboratory must demonstrate that the Initial Precision and Recovery requirements of the method can be met using the clean-up procedure.

A labeled clean-up standard $^{37}\text{Cl}_4$ 2,3,7,8-TCDD is added to the sample just before the back extraction with base and acid procedure. This occurs before any recommended clean-up procedures are initiated.

7.3.1 Was the percent recovery of the clean-up standard within the recommended range listed on Table 6 of the Analytical method?

ACTION: If no, and the recovery is less than 25%, qualify all data as estimated "J". If recovery is 0 %, qualify all positive data as estimated "J" and reject "R" all non-detects for that sample.

7.3.2 Check the chromatograms that clean-up procedure was needed for each sample. Were any clean-up procedures needed for either water or soil samples?

ACTION: If yes, check extraction log to verify which clean-up procedures if any were performed. The laboratory is not limited to only one procedure.

1. If no clean-up was performed and the chromatograms indicated that some should have been performed. Use professional judgement to assess the effect on the interference on the validity of the data. Document lack of required clean-up for complex samples in Data Assessment.
2. If one type of clean-up was performed, but the chromatograms indicate that additional clean-up should have been utilized. Use professional judgement to assess the effect on the interference on the validity of the data. Document lack of additional clean-up for complex samples in Data Assessment.

YES NO N/A

7.3.3 If clean-up procedures were used, did the Laboratory perform clean-up procedures on the Initial Precision and Recovery samples as required by the method?

ACTION: If no, Use professional judgement to assess the effect of the interference on the validity of the data. Document lack of IPR documentation for clean-up procedures in Data Assessment.

8.0 Estimated Detection Limits (EDL) If required for the project

8.1 Was an EDL calculated for each 2,3,7,8-substituted analyte that was not identified regardless of whether other non-2,3,7,8 substituted analytes were present?

ACTION: 1. If EDL or EMPC of an analyte which was not reported as a positive hit is missing, correct manually or contact the Project Officer to request from the laboratory corrections.

8.2 Use the equation below to check EDL calculations:

ALL MATRICES OTHER THAN WATER

$$\text{EDL (pg/g)} = \frac{2.5 \times Q_{is} \times (Hx^1 + Hx^2) \times D}{W \times (His^1 + His^2) \times RR}$$

WATER

$$\text{EDL (pg/L)} = \frac{2.5 \times Q_{is} \times (Hx^1 + Hx^2) \times D}{V \times (His^1 + His^2) \times RR}$$

Where:

Hx^1 and Hx^2 = peak heights of the noise for both quantitation ions of the 2,3,7,8-substituted isomer of interest.

His^1 and His^2 = peak heights of both the quantitation ions of the appropriate internal standards.

D = dilution factor

Q_{is} , RR, W and V are previously defined.

NOTE: The validator should check the EDL data to verify that peak heights and not areas were used for this calculation. If the area algorithm was used, the validator should contact the Project Officer to request recalculations from the laboratory.

ACTION: If the spot check calculations yielded EDLs or EMPCs with $\leq 15\%$ Difference from those reported in Form I, correct manually. If the difference between the validator's value and the Form I's values are $> 15\%$ contact the Project Officer to request from the laboratory for an explanation and a copy of the laboratory's calculations.

9.0 Estimated Maximum Possible Concentration (EMPC) If required for the project

9.1 Was an EMPC calculated for 2,3,7,8-substituted analytes that had S/N ratio for the quantitation and confirmation ions greater than 2.5, but did not meet all the identification criteria?

9.2 Use the equation below to check EMPC calculations:

YES NO N/A

All Matrices other than water

$$\text{EMPC (pg/g)} = \frac{(A_{n1} + A_{n2}) \times Q_i \times D}{W \times (A_{i1} + A_{i2}) \times RR}$$

Water:

$$\text{EMPC (pg/L)} = \frac{(A_{n1} + A_{n2}) \times Q_i \times D}{V \times (A_{i1} + A_{i2}) \times RR}$$

- Action: 1. If EDL or EMPC of an analyte which was not reported as a positive hit is missing, correct manually or contact the Project Officer to request from the laboratory corrections.
2. If the spot check calculations yielded EDLs or EMPCs with < 15% Difference from those reported in Form I, correct manually. If the difference between the validator's value and the Form I's values are > 15% contact the Project Officer to request from the laboratory for an explanation and a copy of the laboratory's calculations.
3. If EDLs or EMPCs for the most toxic analytes (TEF \geq 0.05) are above reporting limits, contact the project office to recommend sample reanalysis.

10.0 Method Blanks

- 10.1 Has a method blank per matrix been extracted and analyzed with each batch of 20 samples?
- 10.2 If samples of some matrix were analyzed in different events (i.e. different shifts or days) has one blank for each matrix been extracted and analyzed for each event?
- 10.3 Acceptable method blanks must not contain any signal of 2,3,7,8-TCDD, or 2,3,7,8-TCDF, equivalent to a minimum levels listed in Table 2 or above one third the regulatory compliance level.. Was this criteria met? (Method 1613B, Section 9.5.2)
- 10.4 For other 2,3,7,8- substituted CDD/CDF isomers of each homologue, the allowable concentration in the method blank is less than minimum level listed in Table 2 (< 5 ng/Kg for soils and 50 pg/L for waters). Was this criteria met?

- ACTION: 1. If the proper number of method blanks were not analyzed, document in Data Assessment. If the validator feels that the validity of the data is seriously compromised and validation of data without the method blanks would be flawed then notify the Project Officer. If decision is made to proceed with the validation process, consider the following actions: no action taken on non-detected analytes. If an analyte has a reported concentration that is > 5 times the EDL, qualify "J" and all concentrations \leq 5 times the EDL are qualified "R" due to possibility of contamination.
2. If the method blank is contaminated with 2,3,7,8-TCDD, 2,3,7,8-TCDF, 1,2,3,7,8-PeCDD, 1,2,3,7,8-PeCDF or 2,3,4,7,8-PeCDF at a concentration higher than the minimum levels in Table 2, reject all contaminant compound positive data for the associated samples "R" and notify the Project Officer to initiate reanalysis.
3. A. If the method blank is contaminated with any of the analytes mentioned in Action # 2 at a concentration of less than the minimum levels in Table 2 specified in the method or of any other 2,3,7,8-substituted analytes at any concentration and the concentration in the sample is less than five times the

YES NO N/A

concentration in the blank, transfer the sample results to the EMPC/EDL column and cross-out the value in the concentration column in order to present the data as a non-detect.

- B. If the concentration in the sample is higher than five times the contamination concentration in the blank, no action is needed.

11.0 Labeled Compound Recoveries

- 11.1 Were the samples spiked with all the labeled compounds as specified in the method? ___ ___
- 11.2 Have labeled compounds' recoveries been within the required limits? ___ ___
- 11.3 If not, were samples reanalyzed? ___ ___

- ACTION: 1. If the labeled compound recovery was below 25 percent, reject "R" all associated non-detect data (EMPC/EDL) and flag with "J" the positive data for the associated compound.
2. If the labeled compound recovery is above the upper limit (150 percent) flag associated positive data with "J". No effect on non-detects.
3. If the labeled compound recovery is less than 10%, qualify positive hits and non-detects associated with the failed labeled compound "R" (Reject). When highly toxic analytes (TEF_> 0.05) are affected, notify Project Officer to initiate reanalysis.

Recalculate the percent recovery for each labeled standard in the sample extract, Rec_i, using the formula:

$$\% \text{ Rec}_i = \frac{(A_{i1} + A_{i2}) \times Q_{is} \times 100}{(A_{is1} + A_{is2}) \times \text{RF} \times Q_i}$$

A_{i1} + A_{i2} = integrated areas of the two quantitation ions of the appropriate labeled compound.

A_{is1} + A_{is2} = integrated areas of the two quantitation ions of the appropriate internal standard.

Q_i = quantity of the appropriate labeled compound

Q_{is} = quantity of the appropriate internal standard injected

RF was defined, previously.

12.0 Internal Standard Area Response

There is no method criterion for the Internal Standard area response. However, because it is very critical in determining instrument sensitivity, the Internal Standard area response should be checked for every sample. The two standards ¹³C₁₂1,2,3,4-TCDD and ¹³C₁₂1,2,3,7,8,9-HxCDD are referred to as Internal Standards in this method. In other Dioxin methods, the two standards are called Recovery Standards.

- 12.1 Are the internal standard areas for every sample and blank within the upper and lower limits of each associated initial calibration CS3?

Area upper limit = +100% of internal standard area.

Area lower limit = -50% of internal standard area.

___ ___

YES NO N/A

12.2 Is the retention time of each internal standard within 15 seconds of the associated initial calibration CS3 standard?

- ACTION: 1. If the internal standard area is outside the upper or lower limits, flag all related positive and non-detect data (EMPC/EDL) with "J" regardless whether the lab's labeled compound recoveries met specifications or not.
2. If extremely low area counts (<25%) are reported, flag all associated non-detect data as unusable "R" and the positive data "J".
3. If the retention time of the internal standards differs by more than 15 seconds from the initial calibration CS3, use professional judgement to determine the effect on the results. A time shift of more than 15 seconds may cause certain analytes to elute outside the retention time window established by the GC window defining/column performance check solution. A constant shift could be also the result of a leak.

NOTE: Action 1 and 2 are recommendations only since this criterion is not a method requirement. These guidelines are based on other methods, previously validated data packages and Region II recommendations. If method blanks have low area responses as well as the samples, the validator should seriously consider qualifying the data for this criterion. Action 3 is a method requirement.

13.0 Second Column Confirmation

13.1 Any sample in which 2,3,7,8-TCDF is identified on a DB-5 column, must have a confirmation analysis (Method 1613B, section 16.5). Was a second column confirmation performed?

13.2 Was the sample extract reanalyzed on a 30 m DB-225, fused silica capillary column, for 2,3,7,8-TCDF using the GC/MS conditions given in Section 10.1.1 of the analytical method?

NOTE: The concentration of 2,3,7,8-TCDF obtained from the primary column (DB-5) should only be used for qualification, due to better QC data associated with the primary column. Also note that the confirmation and quantitation of 2,3,7,8-TCDF may be accomplished on a SP-2330 GC column.

ACTION: If confirmation is missing, use professional judgement, or contact the Project Officer for assistance.

13.3 Did the second column meet the calibration and linearity specification in Sections 5.0 and 6.0 above?

ACTION: If no, refer to section 5.0 and 6.0 for appropriate action.

13.4 Was the % D of the quantitation results of the two columns less than 50?

ACTION: Note in data assessment the differences, use professional judgement to decide which column data to report for TCDF. No other action is needed since this is not a method requirement but a technical recommendation.

14.0 Sample Reanalysis

14.1 The Project Officer will evaluate the need for reanalyzing the samples with qualified data based on site-specific Data Quality Objectives.

YES NO N/A

14.2 Due to a variety of situations (see below) that may occur during sample analysis, the laboratory is required to reanalyze or re-extract and reanalyze certain samples. If a reanalysis was required but was not performed, contact the Project Officer to initiate reanalysis. List in data assessment all re-extractions and reanalyses and identify the CDD/CDF sample data summaries which must be used by the data user (when more than one analysis is submitted for a sample).

Lab must re-extract and/or re-analyzed samples when the following criteria are not met:

1. Contaminated method blank at concentrations above the minimum levels (Table 2)
2. Labeled compound recoveries outside acceptable ranges listed on Table 6 of Analytical method.
3. Exceedance of calibration range by an analyte (dilution or re-extract using a smaller aliquot).
4. Recovery of labeled compounds outside acceptable limits listed on Table 6 of the Analytical method in a diluted sample (re-extracted using a smaller aliquot).

ACTION: For criteria 1, 2, or 3, notify the Project Officer to discuss possible re-analysis of sample by the laboratory.

For criteria 4, If the calibration was verified and the re-extracted sample still does not meet labeled recovery requirements, then the method does not apply to the sample. The results are not reportable for regulatory purposes (Method 1613B, section 18.4.4). Notify the Project Officer of problem to initiate re-analysis of sample using a different method. Document in Data Assessment.

15.0 Precision and Recovery (PAR)

The laboratory is required to show initial demonstration of capability, to evaluate and document data quality. Laboratory performance is compared to established performance criteria to determine if results of analyses meet the performance characteristics of the method.

The laboratory must perform and submit data to establish the ability to generate acceptable precision and accuracy.

15.1 Did the laboratory analyzed an Initial Precision and Recovery (IPR) standard as outlined in section 9.2 required by the analytical method?

ACTION: If no, contact the Project Officer to request resubmittals from the laboratory.

If data is not available, discuss with the Project Officer the feasibility of continuing with validation. If a decision is made to proceed with validation, use professional judgement. All data at a minimum should be qualified as estimated "J". Technically according to the method, data and system performance unacceptable for all compounds. Analyses should not have continued as per the method. Document under contract non-compliance in Data Assessment.

15.2 Did the IPR standard deviation (s) and average concentration (x) passed criteria as outlined in Table 6 of the method?

ACTION: If no, refer to action from section 15.1.

The laboratory must analyzed an Ongoing Precision and Recovery standard (OPR) periodically, at the beginning of 12

YES NO N/A

hour shift after the analysis of the CS3 calibration verification (VER), and before the analysis of any sample in each set

15.3 Was the Ongoing Precision and Recovery (OPR) standard analyzed at the required frequency?

15.4 Did the OPR standard passed the concentration criteria limits in Table 6 of the method?

ACTION: If no, refer to action from section 15.1. All samples that do not have a passing OPR standard are potentially affected for that analyte.

The following sections may be incorporated in the validation process on a case by case basis depending upon the requirements of the Project Plan. Sometimes a laboratory will provide data for some of the following sections on a routine basis. If not a requirement of the Project Plan, then professional judgement is needed to qualify data based on additional information.

16.0 Isomer Specificity and Toxicity Equivalency Factor (TEF)

NOTE: The TEF value concentrations can be found in the DFLM011 Statement of Work for Dioxin Analysis Form I PCDD-2.

When calculating the 2,3,7,8-TCDD Toxicity Equivalency of a sample only those 2,3,7,8 substituted isomers that were positively identified in the sample must be included in the calculations. The sum of the TEF adjusted concentration is used to determine when a second column confirmation is required to achieve analyte specificity.

16.1 Did the lab include EMPC or EDL values in the toxicity equivalency calculations?

16.2 Were all samples, whose toxicity equivalency exceeded the required values were reanalyzed on a confirmation column to establish analyte specificity?

ACTION: 1. If yes, the toxicity equivalency calculations were not calculated properly, notify the Project Officer to arrange for laboratory resubmittals.

2. If the toxicity equivalency exceeded the required limits (0.7 $\mu\text{g}/\text{Kg}$ for soil/ sediment, 7 ng/L for aqueous and 7 $\mu\text{g}/\text{Kg}$ for chemical waste samples), and the lab failed to reanalyze the samples on a specific secondary column, notify Project Officer. Reanalysis may be initiated.

NOTE: Any qualifications such as "J" applied to target compounds should be also applied to their associated total congeners concentration.

17.0 Rinsate Blank (Region 2 QA guidelines recommend rinse blanks for all projects)

17.1 One rinsate blank should be collected for each batch of 20 soil samples or one per day whichever is more frequent. Were rinsate blanks collected at the above frequency?

17.2 Do any rinsate blanks show the presence of 2,3,7,8-TCDD, 2,3,7,8-TCDF, and 1,2,3,7,8-PeCDD at amounts > .5 $\mu\text{g}/\text{L}$ or any other analyte at levels > 1 $\mu\text{g}/\text{L}$?

ACTION: If any rinsate blank was found to be contaminated with any of the CDDs/CDFs notify the Project Officer to discuss what proper action must be taken.

If any qualification is needed due to rinsate blank contamination, follow the guidelines

YES NO N/A

outlined under Method Blanks, section 10, Actions 2 and 3.

18.0 Field Blanks

18.1 The field blanks are PEM samples (blind blanks) supplied to Laboratory at the frequency of one field blank per 20 samples or one per samples collected over a period of one week, whichever comes first. A typical "field blank" will consist of uncontaminated soil. The field blanks are used to monitor possible cross contamination of samples in the field and in the laboratory.

Were the following conditions met?

18.2 Acceptable field blanks must not contain any signal of 2,3,7,8-TCDD, 2,3,7,8-TCDF, 1,2,3,7,8-PeCDD and 1,2,3,7,8-PeCDF equivalent to a concentration of > 20 ng/Kg.

18.3 For other 2,3,7,8 substituted CDD/CDF analytes of each homologue the allowable concentration in the field blank is less than the upper MCLs listed in the method.

ACTION: When the field blank is found to be contaminated with target compounds, apply the same action as described for the Method Blank, section 10, Actions 2 and 3.

NOTE: Ask Project Officer to verify that the PEM blank (field blank) did not contain any CDD/CDF analytes and ask their assistance in the evaluation of the PEM field blank.

19.0 PEM Interference Fortified Blanks

NOTE: This type of blank may not be available at this time. In many cases, laboratories will substitute matrix spike/matrix spike duplicate (MS/MSD). If a PEM Interference Fortified blank(s) were not analyzed but MS/MSD data were submitted, skip this section and go onto to section 21.

19.1 One known blank usually an interference fortified soil/sediment sample is supplied to the Laboratory. The frequency of this QC sample is one per group of 20 environmental samples or one per samples collected over one week period, whichever occurs first. The sample is spiked by the laboratory with the appropriate volume of the matrix spiking solution and then extracted and analyzed with other samples.

19.2 Was a fortified PEM blank analyzed at the frequency described above?

19.3 Was the percent recovery of 2,3,7,8-TCDD and other 2,3,7,8-substituted compounds within the 50 to 150 percent control limits?

ACTION: 1. If the recovery of a 2,3,7,8-substituted analytes falls outside the 50-150 percent control limit, flag all positive and non-detect data of the same and related analytes in the same homolog series with "J". However, if the recovery is below 20%, qualify all associated non-detects "R" and positive hits as "J". Notify the Project Officer. Reanalysis may be initiated.

2. If no fortified PEM blank was analyzed, use professional judgement to assess data validity.

20.0 Matrix Spike (MS) Field Sample

Note: Matrix spike is not required by this method although Labs may routinely perform this analysis as part of internal QA/QC and submit this data as part of the package. Verify requirements with Project Officer.

- | | | YES | NO | N/A |
|------|--|--------------------------|--------------------------|--------------------------|
| 20.1 | Was a matrix spike analyzed at the frequency of one per SDG samples per matrix? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| 20.2 | Was the percent recovery of 2,3,7,8-TCDD and other 2,3,7,8-substituted CDDs/CDFs within 60 to 140 percent? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

ACTION: If problems such as interferences are observed, use professional judgement to assess the quality of the data. The 60-140% limits of the matrix spike data may be used to flag data of the spiked sample only. The matrix spike data of the PE blank sample are more important and must be used primarily in data validation.

- | | | | | |
|------|---|--------------------------|--------------------------|--------------------------|
| 20.3 | Was a matrix spike duplicate analyzed as per section 11.1 and 11.2? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
|------|---|--------------------------|--------------------------|--------------------------|

ACTION: No action required. A matrix spike duplicate is not required. Use professional judgement if there is a large difference in concentrations reported between MS and MSD. Qualifications if any, can only be performed on the sample that was used for this criteria.

21.0 Environmental Duplicate Samples (recommended in Region 2 for all Projects)

NOTE: Do not confuse an environmental duplicate with a matrix spike duplicate. An environmental duplicate is a sample that has been divided into 2 parts (extracted and analyzed as two different samples) or as 2 separate samples from the same location sent by the sampling crew. This sample is not spike with any additional compounds other than those compounds required by the method for analysis of all routine samples.

- | | | | | |
|------|---|--------------------------|--------------------------|--------------------------|
| 21.1 | For every batch of 20 samples or samples collected over a period of one week, whichever is less, there must be a sample designated as duplicate. Were duplicate samples collected at the above frequency? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| 21.2 | Did results of the duplicate samples agree within 25% relative difference for 2,3,7,8-substituted analytes and 50% for the rest of the analytes? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

ACTION: The duplicate results can be used in conjunction of other QC data. Use professional judgement.

LABORATORY:
SITE:

DATA ASSESSMENT

The current Functional Guidelines for evaluating dioxin/furans organic data have been applied.

All data are valid and acceptable except those analytes which have been qualified with a "J" (estimated), "N" (presumptive evidence for the presence of the material), "U"(non-detects), "R" (unusable), or "JN"(presumptive evidence for the presence of the material at an estimated value). All action is detailed on the attached sheets.

Two facts should be noted by all data users. First, the "R" flag means that the associated value is unusable. In other words, due to significant QC problems, the analysis is invalid and provides no information as to whether the compound is present or not. "R" values should not appear on data tables because they can not be relied upon, even as a last resort. The second fact to keep in mind is that no compound concentration, even if it has passed all QC tests, is guaranteed to be accurate. Strict QC serves to increase confidence in data but any value potentially contains error.

Data Completeness and Deliverables

Are the Field Chain of Custody Forms present for all samples?

Are the Narrative, extraction logs, % solid worksheet, analysis logs and Cover Letter present?

Do the Field Chain of Custody Reports or Lab Case Narrative indicate problems with sample receipt, sample condition, analytical procedures, or other comments regarding the quality of the data?

ACTION: Use professional judgment to evaluate the effect of the noted problems on the quality of the data.

ACTION: If any solid sample analyzed contains 50% to 90% water, all data shall be flagged as estimated "J". If a solid sample contains more than 90% water, then qualify positive hits "J" and non-detects "R".

Preservation Requirements

Is the cooler temperature $\leq 10^{\circ}\text{C}$ for aqueous and soil samples from the time of collection until receipt at the laboratory?

ACTION: If cooler temperature $>10^{\circ}\text{C}$, flag non-detects as "UJ" and detects as "J".

Reporting Requirements and Deliverables

Are the following forms present?

Toxic CB Congener Sample Data Summary (Form I CB-1)? _____

Toxic CB Congener Toxicity Equivalency (Form I CB-2)? _____

CB Congener Sample Data Summary (Form I CB-3)? _____

NOTE: Form I is used for tabulating and reporting sample analyses, including dilutions, reanalyses, blanks, LCS/Ongoing Precision and Recovery (OPR) and requested matrix spike and matrix spike duplicates for target compounds.

CB Congener Total Homologue Concentration Summary (Form II CB)? _____

NOTE: Form II is used to report the concentration of the mono- through nano-chloro biphenyl homologue for each sample.

CB Congener Method Blank Summary (Form IV CB-1)? _____

NOTE: Form IV summarizes the sample associated with each method blank analysis.

CB Congener Descriptor Switching Resolution Summary (Form V CB-1)? _____

NOTE: Form V CB-1 is used to report the descriptor switching windows for each level of chlorination for each 12-hour time period and to summarize the date and time of analysis, including dilutions, reanalysis, standards, blanks, and requested MS/MSD associated with each analysis of the instrument performance check solution.

CB Congener Ion Abundance Ratio Summary (Form V CB-2)? _____

CB Congener (Labeled) Ion Abundance Ion Ratio Summary (Form V CB-3)? _____

NOTE: Form V CB-2 & CB-3 are used to report the ion abundance ratios and signal-to-noise (S/N) ratios for the congeners contained in the LOC/WDM for each 12-hour time period.

Toxic CB Congener Initial Calibration Response Factor Summary (Form VI CB-1 & CB-2)? _____

Individual Congener Initial Calibration Response Factor Summary (Form VI CB-3)? _____

Y N N/A

NOTE: Form VI is used to report the relative response factors (RRF), average RRF, % RSD and RRT for the five or six-point initial calibration at the specific concentration levels.

Toxic CB Congener Continuing Calibration Summary (Form VII CB-1)? _____

Toxic CB Congener (Labeled) Continuing Calibration Summary (Form VII CB-2)? _____

Individual Congener Continuing Calibration Summary (Form VII CB-3)? _____

Toxic CB Congener Continuing Calibration Time Summary (Form VII CB-4)? _____

Toxic CB Congener (Labeled) Continuing Calibration Summary (Form VII CB-5)? _____

Individual Congener Continuing Calibration Summary (Form VII CB-6)? _____

NOTE: Form VII is used to report the calibration verification of the HRGC/HRMS system by the analysis of specific calibration verification standard(s). This form is required for each continuing calibration (one every 12 hours of sample analysis).

CB Congener Analytical Sequence (Form VIII CB)? _____

NOTE: Form VIII is used to report the analytical sequence for CB congener analyses.

ACTION: If deliverables are missing, contact the laboratory to request explanation/resubmittal. Note in the Data Assessment.

Holding Times

Were the following holding times met:

Aqueous samples were extracted within 30 days of sample collection _____

Solid samples were extracted within 30 days of sample collection _____

All samples were analyzed within 40 days of extraction _____

ACTION: If holding times are exceeded, flag all data as estimated "J". Holding time criteria do not apply to PE samples.

If holding times from collection to extraction, or from extraction to analysis have been grossly exceeded, use professional judgment to determine whether non-detects shall be rejected.

Column Performance

Y N N/A

Column performance is assessed based on the evaluation of data obtained from the daily (12-hr. shift) diluted combined 209 congener solution.

The retention time for decachlorobiphenyl (PCB 209) must be greater than 55 minutes.

The column, SPB-Octyl, must uniquely resolve congeners 34 from 23 and 187 from 182, and congeners 156 and 157 must co-elute within 2 seconds at peak maximum.

An alternative Column Performance criteria when using DB-1 is as follows:

- a. The retention time for decachlorobiphenyl must be greater than 55 minutes
- b. The column must resolve the following congeners:
 - i. 28,31 with a valley height less than 50 percent
 - ii. 66,70,74,80 with a valley height less than 40 percent
 - iii. 123,118 with a valley height less than 40 percent
 - iv. 156,157 with a valley height less than 40 percent

NOTE: Unique resolution means a valley height of less than 40% of the shorter of the two peaks.

ACTION: If column performance criteria were not met, a detailed discussion of the problems observed and potential effects on analytical data obtained should be included in the data assessment narrative.

Initial 5-Point Calibration

The initial calibration standard solutions (CS1-CS5) must be analyzed prior to any sample analysis. These calibration standards should include all CBs listed at the concentrations specified in Table 5 of Method 1668A. They do not have to be analyzed daily provided the continuing calibration standard met all criteria. The calibration standards must be analyzed on the same instrument using the same GC/MS conditions that were used to analyze samples.

SIM data were acquired for each of the ions listed in Table 7, Method 1668A

The following criteria must be met:

For all target analyte PCBs with associated labeled analogs, the two ions for each CB must maximize simultaneously and within 3 seconds of the corresponding labeled isomer ions.

Y N N/A

For the other CBs, the 2 ions for each of the CBs being quantified must maximize simultaneously.

The relative ion abundance criteria listed in Table 8, Method 1668A must be met.

The relative ion abundance criteria for the labeled internal and recovery standards listed in Table 8, Method 1668A must be met.

For all calibration solutions, the signal to noise ratio (S/N) for all ions of the native compounds must be greater than 10.

For the internal and recovery standards, the signal to noise ratio for all ions must be greater than 10.

The percent relative standard deviation (%RSD) of the five RRFs (CS1-CS5) for the CBs must not be greater than 20 percent.

Spot- check response factor calculations and ion ratios. Ensure that the correct quantitation ions for the unlabeled CBs and internal standards were used. In addition verify that the appropriate internal standard was used for each isomer.

ACTION: If required information was not supplied, notify the lab. If unavailable, reject all associated sample data. If any calibration curve standards fail to meet any acceptance criteria, check for re-calibration and re-analysis.

Calibration by Isotopic Dilution Procedure

(Native CBs included in the Toxics/LOC CBs list)

To recalculate the response factor for targets quantitated based on isotopic dilution, use the equation:

$$RRFn = \frac{(An^1 + An^2) \times C_{is}}{(A_{is}^1 + A_{is}^2) \times C_n}$$

Where:

A_n^1 and A_n^2 = integrated areas of the two quantitation ions of isomer of interest

A_{is}^1 and A_{is}^2 = integrated areas of the two quantitation ions of the appropriate labeled compound.

C_{is} = The concentration of the labeled compound in the calibration standard.

C_n = The concentration of the native compound in the calibration standard.

Calibration by Internal Standard

Y N N/A

(Native CBs not included in the Toxics/LOC CBs list)

Internal standard calibration is performed at a single point using the diluted combined 209-congener solution (Table 3, Method 1668A).

To calculate the response factor for targets based on the internal standard method, use the equation:

$$RF = \frac{(A1_s + A2_s) C_{is}}{(A1_{is} + A2_{is}) C_s}$$

Where:

$A1_s$ and $A2_s$ = The areas of the primary and secondary m/z's for the PCB.

$A1_{is}$ and $A2_{is}$ = The areas of the primary and secondary m/z's for the internal standard.

C_{is} = The concentration of the internal standard.

C_s = The concentration of the compound in the calibration standard.

Continuing Calibration

At the beginning of each 12-hour shift during which analyses are performed, GC/MS system performance and calibration are verified for all native CBs and labeled compounds. For these tests, analysis of the Cs-3 calibration verification (VER) standard (Section 7.10.1 and Table 5, Method 1668A) and the diluted compound 209-congener solution (Section 7.10.2.2 and Table 5, Method 1668A) must be used to verify all performance criteria. Adjustment and/or recalibration (Section 10, Method 1668A) must be performed until all performance criteria are met. Only after all performance criteria are met, may samples, blanks, IPRs and OPRs be analyzed.

Was the continuing calibration run at the required frequency? _____

ACTION: If the continuing calibration standard was not analyzed at the required frequency, reject all the data.

For native Toxics and LOC CBs, the two SIM ions for each PCB must maximize simultaneously and within 3 seconds of the corresponding ions of the labeled isomers. _____

The two ions for each of the CBs being quantified must maximize simultaneously _____

Y N N/A

For the continuing calibration standard solution, the signal to noise ratio (S/N) for the CB ions shall be greater than 10.

The absolute retention times of the labeled Toxics/LOC/window defining standard congeners in the verification test must be within ± 15 seconds of the respective retention times in the calibration. Has this criteria been met?

The relative retention times of native CBs and labeled compounds in the verification test must be within their respective RRT limits in Table 2, Method 1668A. Has the criteria been met?

For the internal standards and the recovery standards, the signal to noise ratio (S/N) shall be greater than 10.

The relative ion abundance criteria, Table 8, Method 1668A for all PCBs native shall be met.

Evaluate the concentrations of the Toxics/LOC CBs in the CS-3 VER standard.

For each compound, compare the concentration with the calibration verification limit in Table 6, Method 1668A. If all compounds meet the acceptance criteria, calibration has been verified and analysis of standards and sample extracts may proceed. Was this criteria met?

Spot-check continuing calibration concentrations and ion ratios. Verify that the appropriate quantitation ions were used for the unlabeled PCBs and internal standards.

ACTION: If the required continuing calibration fail to meet any of the acceptance criteria, check for recalibration and reanalysis. If not performed, reject ("R" flag) all data associated with the analyte out of specification in the continuing calibration.

Sample Data

SIM data were acquired for each of the ions listed in Table 7, Method 1668A

Identification Criteria

- A. For native Toxics and LOC CBs, the two ions for each of the PCB's being quantified must maximize simultaneously and within 3 seconds of the corresponding labeled standard.

Y N N/A

- For the remaining CBs, the two ions for each of the CBs being quantified must maximize simultaneously. _____
- B. The integrated ion current for each characteristic ion of the analyte identified as positive must be at least 2.5 times background noise and must have not saturated the detector. _____
- C. The integrated ion current for the internal and recovery standard characteristic ions must be at least 10 times background noise. _____
- D. The relative ion abundance criteria (Table 8, Method 1668A) for all PCB's found present must be met or ion ratios must be within $\pm 15\%$ of the most recent CS-3 determination. _____
- E. The relative retention time of the peak for a positively identified CB must be within the RRT QC limits specified in Table 2, Method 1668A, or, if an alternate column or column system is employed, within its respective RRT QC limits for the alternate column or column system. _____

ACTION: Reject ("R" flag) all positive data for the analytes which do not meet criteria listed in section A.

If the criteria listed in section B are not met but all other criteria are met, qualify all positive data of the specific analyte with "J".

If the requirements listed in section C are not met but all other requirements are met qualify the positive data of the corresponding analytes with "J".

If the analytes reported positive do not meet ion abundance criteria, section D, or do not meet RRT criteria, Section E, reject "R" all positive data for these analytes. Change the positive values to EMPC (estimated maximum possible concentration).

Spot check calculations for positive data and verify that the same internal standards used to calculate RRFs were used to calculate concentration. _____

Compute the concentrations in the extract of the Native Toxics/LOC CBs, using the RRs from the calibration data and following equation:

$$C_{ex} \text{ (ng/mL)} = \frac{(A1_n + A2_n) C_i}{(A1_l + A2_l) RR}$$

Where:

C_{ex} = The concentration of the PCB in the extract, and the other terms as defined in Section 10.5.1, Method 1668A.

Internal Standard Quantitation and Labeled Compound Recovery

Compute the concentrations in the extract of the native compounds other than those in the Native Toxics/LOC standard, in the Labeled cleanup standard, and in the Labeled injection internal standard (except for Labeled CB178), using the response factors determined from the calibration data and the following equation:

$$C_{ex} \text{ (ng/mL)} = \frac{(A1_s + A2_s) C_{is}}{(A1_{is} + A2_{is}) RF}$$

Where:

C_{ex} = The concentration of the labeled compound in the extract. The other terms are defined on page 7 under calibration by Internal Standard.

Using the concentration in the extract determined above, compute the percent recovery of the Labeled Toxics/LOC/window-defining CBs and the Labeled cleanup standard CBs using the following equation:

$$\text{Recovery (\%)} = \frac{\text{Concentration found (ug/mL)} \times 100}{\text{Concentration spiked (ug/mL)}}$$

The concentration of a native CB in the solid phase of the sample is computed using the concentration of the compound in the extract and the weight of the solids as follows:

$$\text{Concentration in solid (ng/kg)} = \frac{(C_{ex} \times V_{ex})}{W_s}$$

Where:

C_{ex} = The concentration of the compound in the extract.

V_{ex} = The extract volume in mL.

W_s = The sample weight (dry weight) in kg.

The concentration of a native CB in the solid phase of the sample is computed using the concentration of the compound in the extract and the weight of the solids as follows:

$$\text{Concentration in solid (ng/kg)} = \frac{(C_{ex} \times V_{ex})}{W_s}$$

Where:

C_{ex} = The concentration of the compound in the extract.

V_{ex} = The extract volume in mL.

W_s = The sample weight (dry weight) in kg.

Y N N/A

The concentration of a native CB in the aqueous phase of the sample is computed using the concentration of the compound in the extract and the volume of water extracted as follows:

$$\text{Concentration in aqueous phase (pg/L)} = \frac{(C_{ex} \times V_{ex})}{V_s}$$

Where:

C_{ex} = The concentration of the compound in the extract.

V_{ex} = The extract volume in mL.

V_s = The sample volume in liters.

Method Blanks

Has a method blank been extracted and analyzed with each batch of 20 samples or less, per matrix?

Was the method blank analyzed immediately after the OPR?

ACTION: If the proper number of method blanks were not analyzed, notify the contractor. If the reviewer is unavailable, reject all positive sample data. However, the reviewer may also use professional judgment to accept or reject positive sample data if no blank was run.

Were any PCBs found at a concentration greater than the PQL in the associated method blank?

ACTION: If an analyte has a reported concentration that is > 5 times the PQL, qualify "J" and all concentrations ≤ 5 times the PQL are qualified "U" due to possibility of contamination.

If the congener concentration in the sample is less than 5x the concentration in the blank, flag the congener reported value with a "U" qualifier.

If the concentration of the congener in the sample is greater than 5x the concentration in the blank, no action is needed.

Rinsate Blank

Was a rinsate blank submitted for analysis for each analytical batch not to exceed 20 samples?

Do any rinsate blanks contain concentrations of PCBs above the PQL?

Y N N/A

ACTION: If an analyte has a reported concentration that is > 5x the PQL, qualify "J" and all concentrations ≤ 5x the PQL are qualified "U" due to possibility of contamination.

If the congener concentration in the sample is less than 5x the concentration in the blank, flag the congener reported value with a "U" qualifier.

If the concentration of the congener in the sample is greater than 5x the concentration in the blank, no action is needed.

Labeled Compound Recoveries

Were the samples spiked with all the internal standards as specified in the method?

Were internal standard recoveries within the method required limits (Table 6, Method 1688A)?

If not, were samples reanalyzed?

ACTION: If the internal standard recovery was outside the acceptance limits (Table 6, Method 1668A) "J" flag all associated positive results.

Labeled Injection Internal Standards

Internal standard areas for every sample and blank within the upper and lower limits of each associated continuing calibration?

Area upper limit = +100% of internal standard area.

Area lower limit = -50% of internal standard area.

Is the retention time of each internal standard within 10 seconds of the associated daily calibration standard?

ACTION: If the internal standard area is outside the upper or lower limits flag all related positive and non-detect data with "J" regardless of whether or not the labeled standard recoveries met specifications.

If extremely low area counts (<25%) are reported, qualify all associated non-detect data as unusable "R" and the positive data "J."

If the retention time of the internal standard differs by more than 10

Y N N/A

seconds from the daily calibration, use professional judgment to determine the effect on the results. A time shift of more than 10 seconds may cause certain analytes to elute outside the retention time window established by the window defining mix.

Matrix Spike/Matrix Spike Duplicate (MS/MSD)

Sample ID of the sample chosen for MS/MSD analysis: _____

For every sample delivery group of 20 or fewer environmental samples was one MS/MSD pair analyzed? _____

NOTE: In order for the MS/MSD to be appropriate for use in qualifying or rejecting associated sample data, the spike level must be within the range of 25% to 400% of the reported sample concentration for either the aqueous or soil sample..

Is the MS recovery within the 60 to 140% acceptance range for either an aqueous or solid sample? _____

ACTION: qualify the value for the analyte in the sample used for the MS/MSD as estimated "J". Use professional judgment in association with signal to noise ratios and internal standard recoveries for the associated sample data to determine the effect on the quality of the associated sample data.

Does the precision of the MS/MSD analyses meet the $\leq 50\%$ RPD criteria? _____

ACTION: Qualify the value for that analyte in the sample used for the MS/MSD as estimated "J"; use professional judgment in association with signal to noise ratios and internal standard recoveries for the associated sample data to determine the effect on the quality of the associated sample data.

Field Duplicate Samples

Sample IDs of the field duplicate pair: _____

For every batch of 20 samples or less collected there must be a sample designated as duplicate. _____

NOTE: For Aqueous: RPD $\leq 20\%$ when target is detected in both field duplicate samples at $\geq 5XPQL$ or concentrations differ by less than 2X the PQL when detects are $< 5X$ PQL for both field duplicate samples.

For Soil: RPD $\leq 50\%$ when target is detected in both field duplicate samples at $\geq 5x$ PQL, or concentration differs by less than 2x the PQL when detects are $< 5x$ PQL for both field duplicate samples.

Y N N/A

ACTION: The duplicate results must be used in conjunction with other QC data. If no hits are reported, precision may be assessed from the internal standard recoveries.

Ongoing Precision and Recovery (OPR)

For every batch of 20 samples or less processed by the laboratory, was an OPR processed?

Do the calculated percent recoveries for all CBs in the associated OPR meet the acceptance limits provided in Table 6, Method 1668A?

ACTION: If the laboratory failed to process an OPR sample with the associated field samples, qualify all target analyte results as estimated "J".

ACTION: If any CB OPR percent recoveries failed to meet the acceptance criteria listed in Table 6, Method 1668A, qualify detects sample results as estimated "J".

Initial Precision and Recovery (IPR)

Was an initial precision and accuracy demonstration performed for the appropriate matrix as per section 9.2 of Method 1668B?

Were the results of the IPR evaluation acceptance when compared to the acceptance limits for each analyte listed in Table 6, Method 1668A?

ACTION: If IPR date was not provided by the laboratory, contact the lab to obtain the results of the IPR study.

ACTION: If the results of the laboratories IPR study do not meet the acceptance criteria for performance tests listed in Table 6, Method 1668A, contact the lab to initiate remediation of technical difficulties.

Data Validation Qualifiers

Qualifier	Description
J	Estimated value (bias undetermined) – The analyte was positively identified; but the associated numerical value is the approximate concentration of the analyte in the sample.
JH	Estimated value (potential high bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential high bias, of the analyte in the sample.
JL	Estimated value (potential low bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential low bias, of the analyte in the sample.
UJ	Estimated non-detect - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
UJL	Estimated non-detect (potential low bias) – The analyte was not detected and the report sample quantitation limit is biased low.
UJH	Estimated non-detect (potential high bias) – The analyte was not detected and the reported sample quantitation limit is biased high.
M	The analytical result reported was obtained from a sediment sample found to contain between 50 and 90 percent moisture and had no other data qualifiers added during the data validating process.
NJ	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.
NJH	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration with a potential high bias, of the analyte concentration.
EMPC	Estimated Maximum Possible Concentration (EMPC).
R	The sample results are rejected. Due to a significant QA/QC problem, the analysis is invalid and provides no information as to whether the analyte is present or not.

V	Vanadium
Zn	Zinc

INTRODUCTION

This document is designed to offer the data reviewer guidance in determining the validity of analytical data generated through the USEPA Contract Laboratory Program (CLP) Statement of Work (SOW) ISM01.X Inorganic Superfund Methods (Multi-Media, Multi-Concentration), hereinafter referred to as the ISM01.2 SOW, and any future editorial revisions of ISM01.2. This guidance is somewhat limited in scope and is intended to be used as an aid in the formal technical review process.

The guidelines presented in the document will aid the data reviewer in establishing (a) if data meets the specific technical and QC criteria established in the SOW, and (b) the validity and extent of bias of any data not meeting the specific technical and QC criteria established in the SOW. It must be understood by the reviewer that acceptance of data not meeting technical requirements is based upon many factors, including, but not limited to site-specific technical requirements, the need to facilitate the progress of specific projects, and availability for re-sampling.

The reviewer should note that while this document is to be used as an aid in the formal data review process, other sources of guidance and information, as well as professional judgment, should also be used to determine the ultimate validity of data, especially in those cases where all data does not meet specific technical criteria.

DATA QUALIFIER DEFINITIONS

The following definitions provide brief explanations of the national qualifiers assigned to results in the data review process.

U	The analyte was analyzed for, but was not detected above the level of the reported sample quantitation limit.
J	The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.
J+	The result is an estimated quantity, but the result may be biased high.
J-	The result is an estimated quantity, but the result may be biased low.
R	The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.
UJ	The analyte was analyzed for, but was not detected. The reported quantitation limit is approximate and may be inaccurate or imprecise.

DATA PACKAGE INSPECTION

For data obtained through the Contract Laboratory Program (CLP), the EXES Data Manager (EDM) is a useful tool in the data review process. For more information about EDM, please refer to the following Sample Management Office (SMO) website:

<https://epasmoweb.fedcsc.com/help/guides/Submit%20and%20Inspect%20Data%20Quick%20Guide%20%28EXES%29.pdf>

EDM will identify any missing and/or incorrect information in the data package. The CLP laboratory may submit a reconciliation package for any missing items or to correct data. If there are any concerns regarding the data package, contact the CLP Project Officer (CLP PO) from the Region where the samples were taken. For personnel contact information, please refer to the following CLP website:

<http://www.epa.gov/superfund/programs/clp/contacts.htm>

HWSS DATA VALIDATION PROCESS

After downloading the data package from EDM, the data validator will use the recommendations in this SOP as well as their own professional judgment to validate the data.

The data will be saved in the following location, under the appropriate case number folder:

G:\DESADIV\HWSS\DATA VALIDATION

The file naming conventions will consist of

- A. case number i.e., 12345
- B. SDG name i.e., MBXY12
- C. level of validation performed i.e., S2BVE

Examples: **12345_MBXY12_S2BVE.xls**

12345_MBXY12_S2BVEM.xls

When data validation is completed, the data package is uploaded for the client to download from the HWSS data delivery website:

<https://epaqpx.rtp.epa.gov/hwssclpdeliverables>

The completed data package includes the Executive Narrative (see Appendix B for template), the Sample Summary Report (see Appendix C for example), and the Electronic Data Deliverable (EDD) (see Appendix D for a list of the column headers included in this document).

PRELIMINARY REVIEW

This document is for the review of analytical data generated through the ISM01.2 SOW and any future editorial revisions of ISM01.2. To use this document effectively, the reviewer should have an understanding of the analytical method and a general overview of the Sample Delivery Group (SDG) or sample Case at hand. The exact number of samples, their assigned numbers, their matrix, and the number of laboratories involved in the analysis are essential information.

It is suggested that an initial review of the data package be performed, taking into consideration all information specific to the sample data package [e.g., Modified Analysis requests, Traffic Report/Chain of Custody (TR/COC) documentation, SDG Narratives, etc.].

The reviewer should also have a copy of the Quality Assurance Project Plan (QAPP) or similar document for the project for which the samples were analyzed. The reviewer should contact the appropriate Regional Contract Laboratory Program Project Officer (CLP PO) to obtain copies of the QAPP and relevant site information. This information is necessary in determining the final usability of the analytical data.

The SDGs or Cases routinely have unique samples that require special attention from the reviewer. These include field blanks and trip blanks, field duplicates, and Performance Evaluation (PE) samples which must be identified in the sampling records. The sampling records (e.g., TR/COC records, field logs, and/or contractor tables) should identify:

1. The Region where the samples were taken, and
2. The complete list of samples with information on:
 - a. Sample matrix;
 - b. Field blanks*;
 - c. Field duplicates*;
 - d. Field spikes*;
 - e. PE samples*;
 - f. Shipping dates;
 - g. Preservatives;
 - h. Types of analysis; and
 - i. Laboratories involved.

* If applicable.

The TR/COC documentation includes sample descriptions and date(s) of sampling. The reviewer must consider lag times between sampling and start of analysis when assessing technical sample holding times.

The laboratory's SDG Narrative is another source of general information. Notable problems with matrices, insufficient sample volume for analysis or reanalysis, samples received in broken containers, preservation, and unusual events should be documented in the SDG Narrative. The reviewer should also inspect any email or telephone/communication logs detailing any discussion of sample or analysis issues between the laboratory, the CLP Sample Management Office (SMO), and the USEPA Region.

Preservation and Holding Times

Action:

NOTE: Apply the action to each sample for which the preservation or holding time criteria was not met.

1. If the pH of aqueous/water metal samples is > 2 at the time of sample receipt, determine if the laboratory adjusted the pH of the sample to ≤ 2 at the time of sample receipt. If not, use professional judgment to qualify the samples based on the pH of the sample and the chemistry of the metal(s) of interest. Qualify results that are \geq Method Detection Limit (MDL) as estimated low (J-), and qualify non-detects as unusable (R).
2. If technical holding times are exceeded, use professional judgment to determine the reliability of the data, based on the magnitude of the additional time compared to the technical requirement and whether the samples were properly preserved. The expected bias would be low. Qualify results that are \geq MDL as estimated low (J-), and qualify non-detects as unusable (R).
3. Due to limited information concerning holding times for soil/sediment samples, it is left to the discretion of the data reviewer whether to apply 180 day holding time criteria to soil/sediment samples. If they are applied, it must be clearly documented in the Data Review Narrative.
4. When the holding times are exceeded, the reviewer should comment in the Data Review Narrative on any possible consequences for the analytical results.
5. When holding times are grossly exceeded, note it for Contract Laboratory Program Project Officer (CLP PO) action.

Table 1. Technical Holding Time Actions for ICP-MS Analysis

Preservation & Holding Time Results	Action for Samples
Aqueous/water metals samples received with pH > 2 and pH not adjusted	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Aqueous/water Metals > 180 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Soil/sediment Metals > 180 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

ICP-MS Tune Analysis

Action:

NOTES: For ICP-MS tunes that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

1. If the ICP-MS instrument was not tuned prior to calibration, the sample data should be qualified as unusable (R).
2. If the tuning solution was not analyzed or scanned at least 5x consecutively or the tuning solution does not contain the required analytes spanning the analytical range, the reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should be recorded in the Data Review Narrative and noted for Contract Laboratory Program Project Officer (CLP PO) action.
3. If the resolution of the mass calibration is not within 0.1 u for any isotope in the tuning solution, qualify all analyte results that are \geq Method Detection Limit (MDL) associated with that isotope as estimated (J), and all non-detects associated with that isotope as estimated (UJ). The situation should be recorded in the Data Review Narrative and noted for CLP PO action.
4. If the %RSD exceeds 5% for any isotope in the tuning solution, qualify all sample results that are \geq MDL associated with that tune as estimated (J), and all non-detects associated with that tune as estimated (UJ). The situation should be recorded in the Data Review Narrative and noted for CLP PO action.

Table 2. ICP-MS Tune Actions for ICP-MS Analysis

ICP-MS Tune Results	Action for Samples
Tune not performed	Qualify all results as unusable (R)
Tune not performed properly	Use professional judgment
Resolution of mass calibration not within 0.1u	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
% RSD > 5%	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)

Calibration

Table 3. Acceptance Criteria for ICV and CCV Standards

Analytical Method	Inorganic Analytes	ICV/CCV Low Limit (% of True Value)	ICV/CCV High Limit (% of True Value)
ICP-MS	Metals	90	110

Action:

NOTES: For initial calibrations or ICVs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.
For CCVs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the QC sample and a subsequent technically acceptable analysis of the QC sample in the analytical run.

NOTE: The data validator shall verify the correlation coefficient by calculating it using the standard concentrations and the corresponding instrument response.

1. If the instrument was not calibrated each time the instrument was set up and an ICV standard was not analyzed before field and QC samples, qualify the data as unusable (R). If the instrument was not calibrated with a blank and at least 5 calibration standards, use professional judgment to qualify results that are \geq Method Detection Limit (MDL) as estimated (J), and non-detects as estimated (UJ). If the calibration curve does not include standards at required concentrations (e.g., a blank and at least one at or below CRQL), use professional judgment to qualify results that are \geq MDL as estimated (J), and non-detects as estimated (UJ). If there was not at least one calibration standard at or below the CRQL for each analyte, qualify results that are \geq MDL but $< 2x$ the CRQL as estimated (J), and non-detects as estimated (UJ) and write it in the Contract Problem/Non-Compliance Section of the Data Review Narrative.
2. If the correlation coefficient is < 0.995 , percent differences are outside the $\pm 30\%$ limit, or the y-intercept \geq CRQL, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ). If the correlation coefficient is < 0.990 , qualify results that are \geq MDL as estimated (J) and non-detects as unusable (R).
3. If the ICV or CCV %R falls outside the acceptance windows, use professional judgment to qualify all associated data. If possible, indicate the bias in the review. The following guidelines are recommended:
 - a. If the ICV or CCV %R is $< 75\%$, qualify non-detects as unusable (R). Use professional judgment to qualify all results that are \geq MDL as unusable (R).
 - b. If the ICV or CCV %R falls within the range of 75-89%, qualify sample results that are \geq MDL as estimated low (J-), and qualify non-detects as estimated (UJ).
 - c. If the ICV or CCV %R falls within the range of 111-125%, qualify sample results that are \geq MDL as estimated high (J+).
 - d. If the ICV or CCV %R is within the range of 111-125%, non-detects should not be qualified.

- e. If the ICV or CCV %R is > 125%, use professional judgment to qualify results that are \geq MDL as estimated high (J+). Non-detects should not be qualified.
- f. If the %R is > 160%, qualify all results that are \geq MDL as unusable (R).
- 4. If the laboratory failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
- 5. Note the potential effects on the reported data due to exceeding the calibration criteria in the Data Review Narrative.
- 6. If calibration criteria are grossly exceeded, note this for CLP Project Officer (CLP PO) action.

NOTE: For critical samples, a further in-depth evaluation of the calibration curve may be warranted to determine if additional qualification is necessary.

Table 4. Calibration Actions for ICP-MS Analysis

Calibration Result	Action for Samples
Calibration not performed	Qualify all results as unusable (R)
Calibration incomplete	Use professional judgment Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Not at least one calibration standard at or below the CRQL for each analyte	Qualify results that are \geq MDL but < 2x the CRQL as estimated (J) Qualify non-detects as estimated (UJ)
Correlation coefficient < 0.995; %D outside $\pm 30\%$; y-intercept \geq CRQL	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Correlation coefficient < 0.990	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as unusable (R)
ICV/CCV %R < 75%	Qualify results that are \geq MDL as unusable (R) Qualify all non-detects as unusable (R)
ICV/CCV %R 75-89%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICV/CCV %R 111-125%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R > 125%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R > 160%	Qualify results that are \geq MDL as unusable (R)

Calibration/Preparation Blanks

Action:

NOTES: For ICBs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCBs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the CCB and a subsequent technically acceptable analysis of the CCB in the analytical run.

For Preparation Blanks that do not meet the technical criteria, apply the action to all samples prepared in the same preparation batch.

NOTES: Convert soil sample result to mg/kg on wet weight basis to compare with the soil preparation result on Form III.

Associated samples are all samples digested with the preparation blank.

1. If the appropriate blanks were not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank (including Preparation Blanks) reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank (including Preparation Blanks) reported with a negative result, whose value is $<$ (-CRQL) qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. Specific “method” actions include:
 - a. If the absolute value of an ICB or a CCB result is $>$ CRQL, the analysis should be terminated. If the analysis was not terminated and the affected samples were not reanalyzed, report non-detects and results that are \geq MDL, but \leq CRQL as CRQL-U. For results that are $>$ CRQL but $<$ Blank Result, report the results at the level of the blank with a “U” qualifier. Use professional judgment to qualify results that are $>$ Blank Result. Note this situation for CLP PO action and record it in the Data Review Narrative.

- b. If the absolute value of the concentration of the Preparation Blank is \leq CRQL, report non-detects and results that are \geq MDL but \leq CRQL as CRQL-U. Use professional judgment to quality results that are $>$ CRQL.
- c. If any analyte concentration in the Preparation Blank is $>$ CRQL, the lowest concentration of that analyte in the associated samples must be 10x the Preparation Blank concentration. Otherwise, all samples associated with that blank with concentrations $<$ 10x the Preparation Blank concentration and $>$ CRQL should be redigested and reanalyzed. Raise the CRQL to the concentration found in the Preparation Blank and report those samples that do not require redigestion (that are \geq MDL but \leq CRQL) as CRQL-U. Note for CLP PO action and record in the Data Review Narrative if the laboratory failed to redigest and reanalyze the affected samples. The reviewer shall then use professional judgment to assess the data.

Table 5. Calibration/Preparation Blank Actions for ICP-MS Analysis

Blank Type	Blank Result	Sample Result	Action for Samples
ICB/CCB	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
ICB/CCB	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ Blank Result	Report at level of Blank Result with a "U"
		$>$ Blank Result	Use professional judgment
ICB/CCB	\leq (-MDL) but \geq (-CRQL)	\geq MDL, or non-detect	Use professional judgment
ICB/CCB	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)
Preparation Blank	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ 10x the Blank Result	Qualify results as estimated high (J+)
		\geq 10x the Blank Result	No action
Preparation Blank	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
Preparation Blank	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)

Inductively Coupled Plasma - Interference Check Sample (ICP-ICS)

Action:

NOTE: For an ICS for ICP-MS that does not meet the technical criteria, apply the action to all samples reported from the analytical run.

NOTE: The laboratory should have analyzed and reported ICS results for all elements being reported from the analytical run and for all interferences (target and non-target) for these reported elements.

1. The raw data may not contain results for interferences. In this case, the reviewer shall use professional judgment to qualify the data. If the data does contain results for interferences, the reviewer should apply the following actions to samples with concentrations of interferences that are comparable to, or greater than, their respective levels in the ICS:
 - a. If the ICS %R for an analyte or interference is $> 120\%$ (or greater than the true value $+ 2x$ the CRQL, as applicable) and the sample results are non-detects, the data should not be qualified.
 - b. If the ICS %R for an analyte or interference is $> 120\%$ (or greater than the true value $+ 2x$ the CRQL, as applicable) qualify sample results that are \geq MDL as estimated high (J+). If the ICS %R (or true value) grossly exceeds the limits, use professional judgment to qualify the data.
 - c. If the ICS %R for an analyte or interference falls within the range of 50-79% (or less than the true value $- 2x$ the CRQL, as applicable) qualify sample results that are \geq MDL as estimated low (J-).
 - d. If the ICS recovery for an analyte falls within the range of 50-79% (or less than the true value $- 2x$ the CRQL, as applicable), the possibility of false negatives exists. Qualify sample non-detects as estimated (UJ).
 - e. If the ICSAB %R for an analyte or interference is $< 50\%$, qualify all sample results that are \geq MDL and all sample non-detects as unusable (R).
2. If results that are \geq MDL are observed for analytes that are not present in the ICS solution, the possibility of false positives exists. An evaluation of the associated sample data for the affected elements should be made. For samples with comparable or higher levels of interferences and with analyte concentrations that approximate those levels found in the ICS, qualify sample results that are \geq MDL as estimated high (J+). Non-detects should not be qualified.
3. If negative results are observed for analytes that are not present in the ICS solution, and their absolute value is \geq MDL, the possibility of false negatives in the samples exists. An evaluation of the associated sample data for the affected analytes should be made. For samples with comparable or higher levels of interferences, qualify non-detects for the affected analytes as estimated (UJ), and results that are \geq MDL but $< 10x$ the absolute value of the negative result as estimated low (J-).
4. If the raw data does not contain results for the interferences, note it in the Data Review Narrative.

5. Actions regarding the interpretation and/or the subsequent qualification of ICP data due to the ICS analytical results can be extremely complex. Use professional judgment to determine the need for the associated sample data to be qualified. The reviewer may need to obtain additional information from the laboratory. All interpretive situations should then be recorded in the Data Review Narrative.
6. If the ICS acceptance criteria are grossly exceeded, note the specifics for CLP PO action.

Table 6. Interference Check Actions for ICP-MS Analysis

Interference Check Sample Results	Action for Samples
ICS %R > 120% (or greater than true value + 2x the CRQL)	Qualify results that are \geq MDL as estimated high (J+)
ICS %R 50-79% (or less than true value - 2x the CRQL)	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICSAB %R < 50%	Qualify all sample data as unusable (R)
Potential false positives in field samples with interferents	Qualify results that are \geq MDL as estimated high (J+)
Potential false negatives in field samples with interferents	Qualify results that are \geq MDL but < 10x the (negative value) as estimated low (J-) Qualify non-detects as estimated (UJ)

Laboratory Control Sample (LCS)

Action:

If the LCS criteria are not met, the laboratory performance and method accuracy are in question. Professional judgment should be used to determine if the data should be qualified or rejected. The following guidance is suggested for qualifying sample data associated with an LCS that does not meet the required criteria.

For an LCS that does not meet the technical criteria, apply the action to all samples in the same preparation batch.

1. **LCS:**
 - a. If the LCS %R falls within the range of 40-69%, qualify sample results that are \geq Method Detection Limit (MDL) as estimated low (J-). If the LCS %R is $> 130\%$, qualify sample results that are \geq MDL as estimated high (J+).
 - b. If the LCS recovery is $> 130\%$ and the sample results are non-detects, the data should not be qualified.
 - c. If the LCS recovery falls within the range of 40-69%, qualify non-detects as estimated (UJ).
 - d. If LCS %R is $< 40\%$, qualify all results that are \geq MDL as estimated low (J-) and all non-detects as unusable (R).
 - e. If the LCS %R is $> 150\%$, qualify all affected data (both detects and non-detects) as unusable (R).
2. If a laboratory fails to analyze an LCS with each SDG, or if a laboratory consistently fails to generate acceptable LCS recoveries, note this for CLP Project Officer (CLP PO) action.
3. Whenever possible, the potential effects on the data due to out-of-control LCS results should be noted in the Data Review Narrative.

Table 7. LCS Actions for ICP-MS Analysis

LCS Result	Action for Samples
%R 40-69%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
%R $> 130\%$	Qualify results that are \geq MDL as estimated high (J+)
%R $< 40\%$	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
%R $> 150\%$	Qualify all results as unusable (R)

Laboratory Duplicate Sample Analysis

Action:

NOTE: For a duplicate sample analysis that does not meet the technical criteria, apply the action to only the field sample used to prepare the duplicate sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

NOTE: Delete "*" from Form IAs.

If one value is $> \text{CRQL}$ and the other value is non-detect, calculate the absolute difference between the value $> \text{CRQL}$ and the MDL and use this difference to qualify sample results.

If more than one lab duplicate sample was analyzed for an SDG, then qualify the associated samples based on the worst lab duplicate analysis.

1. If the appropriate number of duplicate samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for CLP Project Officer (CLP PO) action.
2. If the results from a duplicate analysis for a particular analyte fall outside the control limits for $> 5x$ the CRQL, qualify aqueous sample results that are $\geq \text{CRQL}$ as estimated (J) if the RPD is between 20% - 100% and as unusable (R) if the RPD is $> 100\%$. Qualify soil/sediment sample results that are $\geq \text{CRQL}$ as estimated (J) if the RPD is between 35% - 120% and as unusable (R) if the RPD is $> 120\%$.
3. If the results from a duplicate analysis for a particular analyte fall outside the control limits for $\leq 5x$ the CRQL, qualify those results that are $\geq \text{MDL}$ as estimated (J) and non-detects as estimated (UJ).
4. If a field blank or PE sample was used for the duplicate sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
5. Note the potential effects on the data due to out-of-control duplicate sample results in the Data Review Narrative.

Table 8. Duplicate Sample Actions for ICP-MS Analysis

Duplicate Sample Results	Action for Samples
<i>Aqueous:</i> Both original sample and duplicate sample > 5x the CRQL and 20% < RPD < 100%	Qualify those results that are \geq CRQL as estimated (J)
<i>Aqueous:</i> Both original sample and duplicate sample > 5x the CRQL and RPD \geq 100%	Qualify those results that are \geq CRQL as unusable (R)
<i>Soil/Sediment:</i> Both original sample and duplicate sample > 5x the CRQL and 35% < RPD < 120%	Qualify those results that are \geq CRQL as estimated (J)
<i>Soil/Sediment:</i> Both original sample and duplicate sample > 5x the CRQL and RPD \geq 120%	Qualify those results that are \geq CRQL as unusable (R)
Original sample or duplicate sample \leq 5x the CRQL (including non-detects) and absolute difference between sample and duplicate > CRQL	Qualify those results that are \geq MDL as estimated (J) and non-detects as estimated (UJ)

Spike Sample Analysis

Action:

- NOTE:** For a Matrix Spike that does not meet the technical criteria, apply the action to only the field sample used to prepare the Matrix Spike sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.
- NOTE:** The final spike concentrations required for the various target analytes are presented in the methods described in the Statement of Work (SOW).
- NOTE:** When the sample concentration is < Method Detection Limit (MDL), use SR = 0 only for the purpose of calculating the %R. The actual spiked sample results, sample results, and %R (positive or negative) shall still be reported on Forms VA-IN and VB-IN.
- NOTES:** Not required for Ca, Mg, K, and Na (both matrices); Al and Fe (soil only).
If more than one spiked sample was analyzed for one SDG, then qualify the associated data based on the worst spiked sample analysis.
Disregard the out of control spike recoveries for analytes whose unspiked concentrations are $\geq 4x$ the spike added.
Delete "N" from Form IAs.
1. If the appropriate number of Matrix Spike samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for Contract Laboratory Program Project Officer (CLP PO) action.
 2. If a field blank or PE sample was used for the spiked sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
 3. If the Matrix Spike recovery does not meet the evaluation criteria and a required post-digestion spike was not performed, note this for CLP PO action.
 4. If the Matrix Spike %R is < 30%, verify that a post-digestion spike was analyzed if required. If the post-digestion spike %R is < 75% or is not performed, qualify sample results that are \geq MDL as estimated low (J-) and non-detects as unusable (R). If the post-digestion spike %R is \geq 75%, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
 5. If the Matrix Spike %R is 30-74% and the sample results are \geq MDL, verify that a post-digestion spike was analyzed if required. If the %R for the post-digestion is also < 75% or is not performed, qualify the affected data as estimated low (J-). If the %R for the post-digestion spike is \geq 75%, qualify the affected data as estimated (J).
 6. If the Matrix Spike %R falls within the range of 30-74% and the sample results are non-detects, qualify the affected data as estimated (UJ).

7. If the Matrix Spike %R is > 125% and the reported sample results are non-detects, the sample data should not be qualified.
8. If the Matrix Spike %R is > 125% and the sample results are \geq MDL, verify that a post-digestion spike was analyzed if required. If the %R for the post-digestion spike is also > 125% or is not performed, qualify the affected data as estimated high (J+). If the %R for the post-digestion spike is \leq 125%, qualify the affected data as estimated (J).
9. Note the potential effects on the data due to out-of-control spiked sample results in the Data Review Narrative.

Table 9. Spike Sample Actions for ICP-MS Analysis

Spike Sample Results	Action for Samples
Matrix Spike %R < 30% Post-digestion spike %R < 75%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R < 30% Post-digestion spike %R \geq 75%	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-digestion Spike %R < 75%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-digestion spike %R \geq 75%	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R > 125% Post-digestion spike %R > 125%	Qualify affected results that are \geq MDL as estimated high (J+)
Matrix Spike %R > 125% Post-digestion spike %R \leq 125%	Qualify affected results that are \geq MDL as estimated (J)
Matrix Spike %R < 30% No post-digestion spike performed	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R 30-74% No post-digestion spike performed	Qualify affected results that are \geq MDL as estimated low (J-) and non-detects as estimated (UJ)
Matrix Spike %R > 125% No post-digestion spike performed	Qualify affected results that are \geq MDL as estimated high (J+) Non-detects are not qualified

ICP Serial Dilution

Action:

NOTE: For a serial dilution that does not meet the technical criteria, apply the action to only the field sample used to prepare the serial dilution sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

NOTE: Serial dilution analysis is required only when the initial concentration is greater than 50x the MDL.
Delete “E” from Form IAs.

1. If the required %D criteria are not met, qualify affected aqueous results whose raw data are > MDL as estimated (J) if %D is between 10%-100% and qualify as unusable (R) if %D is $\geq 100\%$. Qualify affected soil/sediment results whose raw data are > MDL as estimated (J) if %D is between 15%-120% and qualify as unusable (R) if %D is $\geq 120\%$.
2. If evidence of positive or negative interference is found, use professional judgment to qualify the associated sample data. Note the potential effects on the reported data in the Data Review Narrative.
3. It should be noted for Contract Laboratory Program Project Officer (CLP PO) action and in the Data Review Narrative if a field blank or PE sample was used for the serial dilution analysis.

Table 10. Serial Dilution Actions for ICP-MS Analysis

Serial Dilution Result	Action for Samples
<i>Aqueous:</i> Sample concentration > 50x MDL and $10\% < \%D < 100\%$	Qualify affected results whose raw data are > MDL as estimated (J)
<i>Aqueous:</i> Sample concentration > 50x MDL and $\%D \geq 100\%$	Qualify affected results whose raw data are > MDL as unusable (R)
<i>Soil/Sediment:</i> Sample concentration > 50x MDL and $15\% < \%D < 120\%$	Qualify affected results whose raw data are > MDL as estimated (J)
<i>Soil/Sediment:</i> Sample concentration > 50x MDL and $\%D \geq 120\%$	Qualify affected results whose raw data are > MDL as unusable (R)
Interferences present	Use professional judgment

ICP-MS Internal Standards

Action:

NOTE: Apply the action to the affected analytes for each sample that does not meet the internal standard criteria.

1. If no internal standards were analyzed with the run, the sample data should be qualified as unusable (R). Record this in the Data Review Narrative and note for CLP Project Officer (CLP PO) action.
2. If less than five of the required internal standards were analyzed with the run, or a target analyte(s) is (are) not associated to an internal standard, the sample data, or analyte data not associated to an internal standard should be qualified as unusable (R). Record this in the Data Review Narrative and note for CLP PO action.
3. If the % Relative Intensities for all internal standards in a sample is within 60-125% of the response in the calibration blank, the sample data should not be qualified.
4. If the %RI for an internal standard in a sample is not within the 60-125% limit, qualify the data for those analytes associated with the internal standard(s) outside the limit as follows:
 - a. If the sample was reanalyzed at a two-fold dilution with internal standard %RI within the limits, report the result of the diluted analysis without qualification. If the %RI of the diluted analysis was not within the 60-125% limit, report the results of the original undiluted analyses and qualify the data for all analytes that are \geq Method Detection Limit (MDL) in the sample associated with the internal standard as estimated (J), and non-detected analytes associated with the internal standard as estimated (UJ).
 - b. If the sample was not reanalyzed at a two-fold dilution, the reviewer should use professional judgment to determine the reliability of the data. The reviewer may determine that the results are estimated (J) or unusable (R).

Table 11. Internal Standard Actions for ICP-MS Analysis

Internal Standard Results	Action for Samples
No internal standards	Qualify all results as unusable (R)
< 5 of the required internal standards	Qualify all results as unusable (R)
Target analyte not associated with internal standard	Qualify all analyte results not associated with an internal standard as unusable (R)
% RI < 60% or > 125%, original sample reanalyzed at 2-fold dilution, and % RI of diluted sample analysis is between 60% and 125%	Do not qualify the data
% RI < 60% or > 125%, original sample reanalyzed at 2-fold dilution, and % RI of diluted sample analysis is outside the 60% to 125% limit	Qualify analytes associated with the failed internal standard that are \geq MDL as estimated (J) and qualify associated non-detects as estimated (UJ)
Original sample not reanalyzed at 2-fold dilution	Use professional judgment Qualify sample results as estimated (J) or unusable (R)

Field Duplicates

Action:

NOTES: For field duplicates that do not meet the technical criteria, apply the action to only the field sample and its duplicate. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

Check the Sampling Trip Report for the field duplicate pair.

Substitute MDL for CRQL when MDL > CRQL.

Do not calculate RPD when both values are non-detects.

If one value is > the CRQL and the other value is non-detect, calculate the absolute difference between the value > the CRQL and the MDL, and use this criteria to qualify the results.

1. If a field duplicate pair was collected and analyzed, calculate and report the RPD when the sample and its field duplicate values are both $\geq 5x$ the CRQL. Calculate and report the absolute difference when at least one value (sample or duplicate) is $< 5x$ the CRQL.
2. When aqueous sample and duplicate values are both $\geq 5x$ the CRQL, and the RPD is $> 20\%$, qualify the sample and its duplicate as estimated (J).
3. When aqueous sample and/or the duplicate value is $< 5x$ the CRQL, and the absolute difference is $>$ the CRQL, qualify results $>$ the MDL as estimated (J) and non-detects as estimated (UJ).
4. When soil/sediment sample and duplicate values are both $\geq 5x$ the CRQL, and the RPD is $> 50\%$, qualify the sample and its duplicate as estimated (J).
5. When soil/sediment sample and/or the duplicate value is $< 5x$ the CRQL, and the absolute difference is $> 2x$ the CRQL, qualify results $>$ the MDL as estimated (J) and non-detects as estimated (UJ).

Table 12. Field Duplicate Actions for ICP-MS Analysis

Sample Type	Field Duplicate Result	Action for Samples
Aqueous	Sample and its field duplicate $\geq 5x$ the CRQL and RPD $> 20\%$	Qualify sample and its duplicate as estimated (J)
	Sample and/or its field duplicate $< 5x$ the CRQL and absolute difference $>$ the CRQL	Qualify results $>$ the MDL as estimated (J) Qualify non-detects as estimated (UJ)
Soil/Sediment	Sample and its field duplicate $\geq 5x$ the CRQL and RPD $> 50\%$	Qualify sample and its duplicate as estimated (J)
	Sample and/or its field duplicate $< 5x$ the CRQL and absolute difference $> 2x$ the CRQL	Qualify results $>$ the MDL as estimated (J) Qualify non-detects as estimated (UJ)

Field/Rinsate/Trip Blanks

Action:

NOTE: Designate “Field Blank” as such on Form IA.
Field Blank results previously rejected due to other criteria cannot be used to qualify field samples.
Do not use Rinsate Blank associated with soils to qualify water samples and vice versa.
If the MDL is > the CRQL, substitute CRQL with 2x the MDL.

1. If the appropriate blanks were not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank reported with a negative result, whose value is $<$ (-CRQL) qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. If the absolute value of any analyte in a Field/Rinsate/Trip Blank is > the CRQL, then the CRQL shall be raised to the level in the Field/Rinsate/Trip Blank and the associated sample data below this level shall be reported as CRQL-U.
5. Sample results > the Field/Rinsate/Trip Blank value but < 10x the Field/Rinsate/Trip Blank value shall be qualified as estimated (J).
6. Sample results \geq the MDL but \leq the CRQL shall be reported at the CRQL value with a “U”.

Table 13. Field/Rinsate/Trip Blank Actions for ICP-MS Analysis

Blank Result	Sample Result	Action for Samples
> CRQL	\geq MDL but \leq CRQL	Report CRQL value with a “U”
	> CRQL but < Blank Result	Report at level of Blank Result with a “U”
	> Blank Result but < 10x the Blank Result	Use professional judgment to qualify results as estimated (J)

Linear Ranges

Action:

1. If any sample result was higher than the high linear range for ICP-MS and the sample was not diluted to obtain the result reported on Form I, qualify the affected results \geq MDL as estimated (J).

Percent Solids of Sediments

Action:

1. If the percent solids in sediment for a sample are $< 50\%$, qualify the affected results \geq MDL as estimated (J) and the non-detects as estimated (UJ).

Regional Quality Assurance (QA) and Quality Control (QC)

Action:

Any action must be in accordance with Regional specifications and criteria for acceptable PE sample results. Note any unacceptable PE sample results for Contract Laboratory Program Project Officer (CLP PO) action.

Overall Assessment

Action:

1. Use professional judgment to determine if there is any need to qualify data which were not qualified based on the QC criteria previously discussed.
2. Write a brief Data Review Narrative to give the user an indication of the analytical limitations of the data. Note any discrepancies between the data and the Sample Delivery Group (SDG) Narrative for Contract Laboratory Program Project Officer (CLP PO) action. If sufficient information on the intended use and required quality of the data is available, the reviewer should include an assessment of the data usability within the given context.
3. If any discrepancies are found, the laboratory may be contacted by the Region's designated representative to obtain additional information for resolution. If a discrepancy remains unresolved, the reviewer may determine that qualification of the data is warranted.

Calculations for ICP-MS

Aqueous/Water Sample Concentration by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS):

The concentrations determined in the digestate are to be reported in units of µg/L:

$$\text{Concentration } \left(\frac{\mu\text{g}}{\text{L}} \right) = C \times \frac{V_f}{V} \times DF$$

Where,

- C = Instrument value in µg/L (The average of all replicate integrations).
- V_f = Final digestion volume (mL)
- V = Initial aliquot amount (mL)
- DF = Dilution Factor

Soil/Sediment Sample Concentration by ICP-MS:

The concentrations determined in the digestate are to be reported on the basis of the dry weight of the sample, in units of mg/kg:

$$\text{Concentration (drywt.) } \left(\frac{\text{mg}}{\text{kg}} \right) = C \times \frac{V_f}{W \times S} \times \frac{DF}{1000}$$

Where,

- C = Instrument value in µg/L (The average of all replicate integrations).
- V_f = Final digestion volume (mL)
- W = Initial aliquot amount (g)
- S = % Solids/100 (see Exhibit D of ISM01.2 - Introduction to Analytical Methods, Section 1.6).
- DF = Dilution Factor

Adjusted Method Detection Limit (MDL)/Adjusted Contract Required Quantitation Limit (CRQL) Calculation:

To calculate the adjusted MDL or adjusted CRQL for aqueous/water samples, substitute the value of the MDL (µg/L) or CRQL (µg/L) into the “C” term in the equation above. Calculate the adjusted MDL or adjusted CRQL for soil/sediment samples as follows:

$$\text{Adjusted Concentration } \left(\frac{\text{mg}}{\text{kg}} \right) = C \times \frac{W_M}{W \times S} \times \frac{V_f}{V_M} \times DF$$

Where,

C	=	MDL or CRQL (mg/kg)
W_M	=	Minimum method required aliquot amount (g) (1.00 g or 0.50 g)
W	=	Initial aliquot amount (g)
V_M	=	Method required final sample digestion volume (mL) (100 mL)
V_f	=	Final digestion volume (mL)
S	=	% Solids/100 (see Exhibit D of ISM01.2 - Introduction to Analytical Methods, Section 1.6).
DF	=	Dilution Factor

APPENDIX A: GLOSSARY

Analyte -- The element of interest, ion, or parameter an analysis seeks to determine.

Analytical Services Branch (ASB) -- Directs the Contract Laboratory Program (CLP) from within the Office of Superfund Remediation and Technical Innovation (OSRTI) in the Office of Solid Waste and Emergency Response (OSWER).

Analytical Sample -- Any solution or media introduced into an instrument on which an analysis is performed excluding instrument calibration, Initial Calibration Verification (ICV), Initial Calibration Blank (ICB), Continuing Calibration Verification (CCV), and Continuing Calibration Blank (CCB). Note that the following are all defined as analytical samples: undiluted and diluted samples (USEPA and non-USEPA); Matrix Spike samples; duplicate samples; serial dilution samples, analytical (post-digestion/post-distillation) spike samples; Interference Check Samples (ICSs); Laboratory Control Samples (LCSs); and Preparation Blanks.

Associated Samples -- Any sample related to a particular Quality Control (QC) analysis. For example, for Initial Calibration Verification (ICV), all samples run under the same calibration curve. For duplicates, all Sample Delivery Group (SDG) samples digested/distilled of the same matrix.

Blank -- A sample designed to assess specific sources of contamination. See individual definitions for types of blanks.

Calibration -- The establishment of an analytical curve based on the absorbance, emission intensity, or other measured characteristic of known standards. The calibration standards are to be prepared using the same type of reagents or concentration of acids as used in the sample preparation.

Calibration Blank -- A blank solution containing all of the reagents in the same concentration as those used in the analytical sample preparation. This blank is not subject to the preparation method.

Calibration Curve -- A plot of instrument response versus concentration of standards.

Calibration Standards -- A series of known standard solutions used by the analyst for calibration of the instrument (i.e., preparation of the analytical curve). The solutions may or may not be subjected to the preparation method, but contain the same matrix (i.e., the same amount of reagents and/or preservatives) as the sample preparations to be analyzed.

Case -- A finite, usually predetermined number of samples collected over a given time period from a particular site. Case numbers are assigned by the Sample Management Office (SMO). A Case consists of one or more Sample Delivery Groups (SDGs).

Continuing Calibration Blank (CCB) -- A reagent water sample that is run 2 hours (ICP-AES, ICP-MS) or every hour (Hg, CN) and designed to detect any carryover contamination.

Contract Compliance Screening (CCS) -- A screening of electronic and hardcopy data deliverables for completeness and compliance with the contract. This screening is performed under USEPA direction by the Contract Laboratory Program (CLP) Sample Management Office (SMO) contractor.

Continuing Calibration Verification (CCV) -- A single parameter or multi-parameter standard solution prepared by the analyst and used to verify the stability of the instrument calibration with time, and the instrument performance during the analysis of samples. The CCV can be one of the calibration standards. However, all parameters being measured by the particular system must be

represented in this standard and the standard must have the same matrix (i.e., the same amount of reagents and/or preservatives) as the samples. The CCV should have a concentration in the middle of the calibration range and shall be run every 2 hours (ICP-AES, ICP-MS) or every hour (Hg, CN).

Contract Laboratory Program (CLP) -- Supports the USEPA's Superfund effort by providing a range of state-of-the-art chemical analytical services of known quality. This program is directed by the Analytical Services Branch (ASB) of the Office of Superfund Remediation and Technical Innovation (OSRTI) of USEPA.

Contract Laboratory Program Project Officer (CLP PO) -- The Regional USEPA official responsible for monitoring laboratory performance and/or requesting analytical data or services from a CLP laboratory.

Contract Required Quantitation Limit (CRQL) -- Minimum level of quantitation acceptable under the contract Statement of Work (SOW).

Duplicate -- A second aliquot of a sample that is treated the same as the original sample in order to determine the precision of the method.

Field Blank -- Any sample that is submitted from the field and identified as a blank. A field blank is used to check for cross-contamination during sample collection, sample shipment, and in the laboratory. A field blank includes trip blanks, rinsate blanks, bottle blanks, equipment blanks, preservative blanks, decontamination blanks, etc.

Field Duplicate -- A duplicate sample generated in the field, not in the laboratory.

Holding Time -- The maximum amount of time samples may be held before they are processed.

Contractual -- The maximum amount of time that the Contract Laboratory Program (CLP) laboratory may hold the samples from the sample receipt date until analysis and still be in compliance with the terms of the contract, as specified in the CLP Analytical Services Statement of Work (SOW). These times are the same or less than technical holding times to allow for sample packaging and shipping.

Technical -- The maximum amount of time that samples may be held from the collection date until analysis.

Initial Calibration -- Analysis of analytical standards for a series of different specified concentrations to define the quantitative response, linearity, and dynamic range of the instrument to target analytes.

Initial Calibration Blank (ICB) -- The first blank standard run to confirm the calibration curve.

Initial Calibration Verification (ICV) -- Solution(s) prepared from stock standard solutions, metals, or salts obtained from a source separate from that utilized to prepare the calibration standards. The ICV is used to verify the concentration of the calibration standards and the adequacy of the instrument calibration. The ICV should be traceable to National Institute of Standards and Technology (NIST) or other certified standard sources when USEPA ICV solutions are not available.

Internal Standard -- A non-target element added to a sample at a known concentration after preparation but prior to analysis. Instrument responses to internal standards are monitored as a means of assessing overall instrument performance.

Interference Check Sample (ICS) -- Verifies the contract laboratory's ability to overcome interferences typical of those found in samples.

Laboratory Control Sample (LCS) -- A control sample spiked at known level(s). LCSs are processed using the same sample preparation, reagents, and analytical methods employed for the USEPA samples received.

Matrix -- The predominant material of which the sample to be analyzed is composed. For the purposes of this document, the matrices are aqueous/water, soil/sediment, wipe, and filter.

Matrix Spike -- Introduction of a known concentration of analyte into a sample to provide information about the effect of the sample matrix on the digestion and measurement methodology (also identified as a pre-distillation/digestion spike).

Method Detection Limit (MDL) -- The concentration of a target parameter that, when a sample is processed through the complete method, produces a signal with 99 percent probability that it is different from the blank. For 7 replicates of the sample, the mean value must be 3.14s above the blank, where "s" is the standard deviation of the 7 replicates.

Narrative (SDG Narrative) -- Portion of the data package which includes laboratory, contract, Case, Sample Number identification, and descriptive documentation of any problems encountered in processing the samples, along with corrective action taken and problem resolution.

Office of Solid Waste and Emergency Response (OSWER) -- The USEPA office that provides policy, guidance, and direction for the USEPA's solid waste and emergency response programs, including Superfund.

Percent Difference (%D) -- As used in this document and the Statement of Work (SOW), is used to compare two values. The difference between the two values divided by one of the values.

Performance Evaluation (PE) Sample -- A sample of known composition provided by USEPA for contractor analysis. Used by USEPA to evaluate Contractor performance.

Post Digestion Spike -- The addition of a known amount of standard after digestion or distillation (also identified as an analytical spike).

Preparation Blank -- An analytical control that contains reagent water and reagents, which is carried through the entire preparation and analytical procedure.

Relative Percent Difference (RPD) -- As used in this document and the Statement of Work (SOW) to compare two values, the RPD is based on the mean of the two values, and is reported as an absolute value (i.e., always expressed as a positive number or zero).

Regional Sample Control Center Coordinator (RSCC) -- In USEPA Regions, coordinates sampling efforts and serves as the central point-of-contact for sampling questions and problems. Also assists in coordinating the level of Regional sampling activities to correspond with the monthly projected demand for analytical services.

Relative Standard Deviation (RSD) -- As used in this document and the Statement of Work (SOW), the mean divided by the standard deviation, expressed as a percentage.

Sample -- A single, discrete portion of material to be analyzed, which is contained in single or multiple containers and identified by a unique Sample Number.

Sample Delivery Group (SDG) -- A unit within a sample Case that is used to identify a group of samples for delivery. An SDG is defined by the following, whichever is most frequent:

- a. Each 20 field samples [excluding Performance Evaluation (PE) samples] within a Case; or
- b. Each 7 calendar day period (3 calendar day period for 7-day turnaround) during which field samples in a Case are received (said period beginning with the receipt of the first sample in the SDG).

c. Scheduled at the same level of deliverable.

In addition, all samples and/or sample fractions assigned to an SDG must be scheduled under the same contractual turnaround time. Preliminary Results have **no impact** on defining the SDG. Samples may be assigned to SDGs by matrix (i.e., all soil/sediment samples in one SDG, all aqueous/water samples in another) at the discretion of the laboratory.

Sample Management Office (SMO) -- A contractor-operated facility operated under the SMO contract, awarded and administered by the USEPA. Provides necessary management, operations, and administrative support to the Contract Laboratory Program (CLP).

Serial Dilution -- The dilution of a sample by a factor of five. When corrected by the Dilution Factor (DF), the diluted sample must agree with the original undiluted sample within specified limits. Serial dilution may reflect the influence of interferents [Inductively Coupled Plasma (ICP) only].

Statement of Work (SOW) -- A document which specifies how laboratories analyze samples under a particular Contract Laboratory Program (CLP) analytical program.

Tune -- Analysis of a solution containing a range of isotope masses to establish Inductively Coupled Plasma - Mass Spectrometry (ICP-MS) mass-scale accuracy, mass resolution, and precision prior to calibration.

APPENDIX B: INORGANIC DATA EXECUTIVE NARRATIVE TEMPLATE

	<p>UNITED STATES ENVIRONMENTAL PROTECTION AGENCY REGION 2 DESA/HWSS/HWSS 3899, Woodbridge Avenue, Edison, NJ 08837</p>	
<u>EXECUTIVE NARRATIVE</u>		
Case No.:	SDG No.:	
Site:	Laboratory:	
QAPP HWSS #: Contractor #:		Number of Samples: Sampling date:
SUMMARY:		
Critical:	Results have an unacceptable level of uncertainty and should not be used for making decisions. Data have been qualified "R" rejected.	
Major:	A level of uncertainty exists that may not meet the data quality objectives for the project. A bias is likely to be present in the results. Data have been qualified "J" estimated.	
Minor:	The level of uncertainty is acceptable. No significant bias in the data was observed.	
<u>Critical Findings:</u>	None	
<u>Major Findings:</u>	None	
<u>Minor Findings:</u>	None

**EDS SOP: Mercury by CVAFS
USEPA 1631, Rev. 1, 5/14**

MERCURY VIA METHOD 1631 VALIDATION SOP REVISION 1

SITE:

DATE/INITIALS:

SDG:

LABORATORY:

Data Completeness and Deliverables

Y N N/A

Have any missing deliverables been received and added to the data package? _____

ACTION: Call lab for explanation/resubmittal of any missing deliverables. If the lab cannot provide them, note the effect on the data review process in the non-compliance section of the data assessment narrative.

Custody Documents and Narratives

Are chains of custody present and complete for all samples? _____

ACTION: Contact lab for replacement of missing documents.

Do chains of custody or lab narratives indicate any problems with sample receipt? _____

Cooler Temperatures:

i.e., condition of samples, analytical problems or special notations affecting the quality of the data.

ACTION: If samples were not iced or melted ice is present in the cooler and cooler temperature was outside the range of 4°C (±2) upon receipt for aqueous and soil, -15°C (±2) for crab and clam samples note in data assessment narrative. If cooler temperature is found to be in excess of 10°C for aqueous/soil, flag all associated Hg results as estimated "J."

Holding Times

Y N N/A

Have any mercury technical holding times, determined from date of collection to date of preparation and analyses been exceeded?

NOTE:

Aqueous: Samples to be analyzed for total or dissolved Hg only are shipped to the laboratory unpreserved in fluoropolymer bottles capped tightly and stored at 4°. Samples must be either preserved or analyzed within 48 hours of collection. Holding time for analysis is 28 days from collection. Soil: No preservatives necessary. Holding time for analysis is 28 days from collection. Clam/Crab Collection: Ziploc® bags and shipped frozen at -15°. Holding time for sample preparation is 60 days. Holding time for analysis is 28 days from the date and time of sample homogenization.

Table of Holding Crab/Crab Collection Time Violations

Sample	Date Collected	Date lab Received	Date of Tissue Preparation
_____	_____	_____	_____
_____	_____	_____	_____

Table of Holding Time Violations

Sample	Sample Matrix	Date Sampled	Date lab Received	Date Preserved	Date Digested	Date/Time Analyzed
_____	_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____	_____

ACTION: If holding times are exceeded, flag all data as estimated "J" for detects and "UJ" for non-detects. If holding times were grossly exceeded (i.e., more than 2x the holding time), flag all positive data as estimated and reject all non-detects as unusable "R".

Sample Preservation

Were the pH values present for aqueous samples?

Were samples properly preserved per Section 8.5.1, Method 1631 (48 hours to preservation)?

NOTE: The pH of all aqueous samples must be tested immediately before aliquotting for processing or direct analysis pH should be < 2.

Y N N/A

Preservation samples may be done by adding 5 mL/L of concentrated HCl (to allow both total and Hg determination) or 5 mL/L BrCl solution, if total mercury only is to be determined.

Laboratory Sample Preparation Log

Are all sample preparation bench sheets and logs present? _____

Matrix Spike/Matrix Spike Duplicate (MS/MSD)

The following sample was selected for MS/MSD analysis: _____

Is a matrix spike/matrix spike duplicate summary present? _____

Were matrix spikes analyzed at the required frequency for each of the analytical sample groups (i.e., 10% minimum per analytical batch)? _____

ACTION: If any matrix spike data are missing, call the lab for explanation/re-submittal. If information is not available document the effect in narrative notes.

MS/MSD limits for aqueous and soils are as follows:

% Recovery = 71-125%
 RPD = ±24%

MS/MSD limits for tissue are as follows:

% Recovery = 71-125%
 RPD = ±35%

Have any matrix spike recoveries failed to meet the criteria listed above in either the MS or MSD? _____

Are any spike recoveries:

Less than 10%? _____

Between 10-70%? _____

Between 126-200%? _____

Greater than 200%? _____

ACTION: If less than 10%, reject all associated aqueous data; if between 10-70%, flag all associated aqueous data as estimated potential low bias "J" or "UJL"; if between 126-200%, flag as estimated "JH" all associated aqueous data not flagged with a "U"; if > 200%, reject (red-line) all associated aqueous data not flagged with a "U."

Y N N/A

Have any MS/MSD relative percent difference (RPD) values failed to meet The acceptance criteria listed above?

ACTION: If any RPD value fails to meet the method acceptance criteria, qualify all associated sample results as estimated "J" or "UJ".

Blanks

Either bubbler blanks or system blanks will be run depending on the type of system used by the laboratory.

Bubbler Blanks (bubbler systems only- if applicable)

Have at least three bubbler blanks been analyzed to demonstrate the bubbler system is free from contamination at levels that could affect data quality?

NOTE: Multiple bubblers may be used, at least one blank per bubbler (maximum 4 bubblers).

Upon examination of the bubbler blank data, do the blanks contain positive results?

NOTE: If the bubbler blank is found to contain more than 50 pg Hg, the system is out of control. The problem must be investigated and remedied, and the samples run on that bubbler must be reanalyzed. If the blanks from other bubblers contain < 50 pg Hg, the data associated with those bubblers remain valid.

The mean result for all bubbler blanks must be < 25 pg, the average peak area or height is subtracted from all raw data before results are calculated.

ACTION: If yes, qualify associated results as follows: "J" flag all positive mercury sample values related to highest concentration of blank contamination.

Prepare a list of samples affected.

System Blanks (flow injection systems only- if applicable)

Have at least three system blanks been analyzed to demonstrate that flow injection systems are free from contamination at levels that could affect data quality?

NOTE: If a system blank is found to contain ≥ 0.50 ng/L Hg, the system is out of control. If the blanks contain < 0.50 ng/L Hg, the data associated with the blanks remain valid.

The mean result for the three system blanks must be < 0.5 ng/L Hg with a standard deviation (n-1) < 0.1 ng/L. If the mean is < 0.5 ng/L, the average peak height or area is subtracted from all raw data before results are calculated.

Y N N/A

Upon examination of the system blank data, do the blanks contain positive results > the MDL?

ACTION: "J" flag all positive mercury sample values related to the highest concentration of blank contamination.

Method Blank

Has a method blank analysis been reported for each sample delivery group not to exceed 20 samples?

NOTE: Three method blanks should accompany each sample delivery group. The mean blank value should be used to evaluate associated sample results.

Is the method blank summary present?

Upon evaluation of associated method blank results, do any method blank results exceed the MDL?

ACTION: If the samples associated with the non-compliant method blank contain positive results for mercury which are < 5x that of the mean method blank value, these sample results should be qualified as "U". Non-detect results are not affected nor are sample results that are > 5x that of the contaminated method blank mean.

Trip Blank

Has a trip blank analysis been reported for each sample delivery shipment?

Upon examination of the trip blank, does it contain any positive results ≥ MDL?

ACTION: If the samples associated with the non-compliant trip blank contain positive results for mercury which are < 5x that of the mean trip blank value, these sample results should be qualified as "U". Non-detect results are not affected nor are sample results that are greater than 5x that of the contaminated trip blank mean.

Field Blank (Only for soil samples. Not applicable for tissue)

Has a field blank analysis been reported for each sample delivery group not to exceed 20 samples?

Has the field blank been analyzed in the proper sequence?

NOTE: The field blank should be analyzed immediately before analyzing samples in the batch.

Y N N/A

Upon examination of the field blank, does it contain any positive results \geq MDL?

ACTION: If the samples associated with the non-compliant field blank contain positive results for mercury which are $< 5x$ that of the mean field blank value, these sample results should be qualified as "U". Non-detect results are not affected nor are sample results that are greater than $5x$ that of the contaminated field blank mean.

Rinse Blank (Only for tissue samples. Not applicable for soil samples)

Has a rinse blank analysis been reported for each sampling event of the decontaminated homogenization equipment in the lab, not to exceed more than one per day?

Upon examination of the rinse blank, does it contain positive target analytes \geq the MDL?

ACTION: If the samples associated with the non-compliant rinse blank contain positive results for mercury which are $< 5x$ that of the rinse blank, these sample results should be qualified as "U". Non-detect results are not affected nor are sample results that are $> 5x$ that of the contaminated rinse blank.

Calibration

Are raw data and summary sheets present for both initial and continuing calibrations?

Are the % relative standard deviation (RSD) values for the initial calibration $\leq 15\%$?

ACTION: Associated sample data for those analytes with % RSD > 15 will be qualified as estimated "J". However, if severe discrepancies exist (i.e., %RSD $> 50\%$) validator may elect to reject associated sample results.

Check calibration factors and % RSD values back to raw data for 10% of data received.

Are mis-calculations or transcription errors found?

NOTE: If yes, contact the laboratory.

If RSD $\leq 15\%$, calculate the recovery for the lowest standard using mean calibration factor (CF_m). If the RSD $\leq 15\%$ and the recovery of the lowest standard is in the range of 75-125%, the calibration is acceptable and CF_m may be used to calculate the concentration of Hg in samples.

Y **N** **N/A**

Is the recovery of the lowest standard in the range of 75-25%?

ACTION: If the recovery is < 75%, flag associated data as estimated "J" for detects and "R" for non-detects. If the recovery is > 125%, flag associated positive data "J".

Quality Control Sample (QCS)

Was a QCS analyzed as an independent check of instrument calibration after the OPR and before the method blank?

NOTE: The laboratory must obtain QCS source from a different source used to produce the standards, Hg.

ACTION: If < 50% recovery flag all associated data as "J". If above 150% recovery flag all associated positive data as "J".

Initial Precision and Recovery (IPR)

Was an initial precision and accuracy demonstration performed for the appropriate matrix per Section 9.5 of Method 1631 (4 replicates of the IPR solution is used to compute an average percent recovery X and the standard deviation of the percent recoveries for Hg)?

Was the results of the IPR evaluation acceptable when compared to the acceptance limit listed in Table 1 (79-121%)?

ACTION: If IPR data was not provided by the laboratory, contact the lab to obtain the results of the IPR study.

If the result of the laboratories IPR study does not meet the acceptance criteria for performance test listed in Table 1 , contact the laboratory to initiate remediation of technical difficulties. Further sample analyses should not be performed until the laboratory satisfactorily demonstrates the IPR performance test.

Ongoing Precision and Recovery (OPR)

Was an OPR standard prepared and analyzed for each sample batch (to a maximum of 20 samples)?

Circle on each OPR summary report percent recoveries outside control limits Listed in Table 1 (77-123%).

Was an OPR analyzed at the beginning and end of an analytical batch run or at the end of each 12-hour shift?

Y N N/A

Is any OPR recovery:

Less than 10%?	_____	_____	_____
Between 10% and 76%?	_____	_____	_____
Between 124% and 150%?	_____	_____	_____
Greater than 150%?	_____	_____	_____

ACTION: Less than 10%, reject (red-line) all data; between 10% and 76%, flag all associated data as estimated (J); between 124% and 150%, flag all positive (not flagged with a "U") results as estimated; greater than 150%, reject all positive results.

Compound Quantitation and Reported Detection Limits

Verify at least one detected mercury results in each sample delivery group. Recalculate from the raw data to check for calculation and transcription errors.

Were miscalculation/transcription errors found? _____

ACTION: If errors are found, contact the lab for explanation/resubmittals.

Are all positive mercury results above the MDL reported with:

three significant figures?	_____	_____	_____
correct units (ng/L, ng/kg), ?	_____	_____	_____

Field Duplicates (Not applicable for tissue samples)

NOTE: To access the precision and accuracy of the sampling, sample transportation and storage techniques.

The following samples comprise the field duplicate pair: _____

Were field duplicates submitted for mercury analysis at a frequency of one per 20 sample delivery group not to exceed field samples per matrix? _____

ACTION: Where both the sample and duplicate values are > 5x the PQL, acceptable sampling and analytical precision is indicated by an RPD for the two field duplicate results of ≤ 20%. Where one or both analytes of the field duplicate pair are < 5x the PQL, satisfactory precision is indicated if the field duplicate results agree within 2x the PQL. If the above criteria are not met for an analyte, qualify all associated sample data for that analyte as estimated "J".

Table 1

Acceptance Criteria For Performance Test

Acceptance Criterion	Section of Method 1631	Limits	Project Quantitation Limit (PQL)
Method Detection Limit	9.2.1	<0.2 ng/L	0.5 ng/L
Initial Precision and Recovery	9.2.2		
Precision(s)	9.2.2.3	+/- 21%	
Recovery (x)	9.2.2.3	79-121%	
Interlaboratory Intercomparison	9.2.2.2	75-125%	
Matrix Spike/Matrix Spike Duplicate	9.3		
Recovery	9.3.4	71-125%	
Relative Percent Difference	9.3.6	+/-24%	
Bubbler Blanks	9.4		
Maximum	9.4.1.2	<50 pg	
Mean	9.4.1.3	<25 pg	
Ongoing Precision and Recovery	9.5	77-123%	

Data Validation Qualifiers

Qualifier	Description
EMPC	Estimated Maximum Possible Concentration (EMPC).
J	Estimated value (bias undetermined) – The analyte was positively identified; but the associated numerical value is the approximate concentration of the analyte in the sample.
JH	Estimated value (potential high bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential high bias, of the analyte in the sample.
JL	Estimated value (potential low bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential low bias, of the analyte in the sample.
M	The analytical result reported was obtained from a sediment sample found to contain between 50 and 90 percent moisture and had no other data qualifiers added during the data validating process.
NJ	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.
R	The sample results are rejected. Due to a significant QA/QC problem, the analysis is invalid and provides no information as to whether the analyte is present or not.
U	Non-detected value – The result initially reported as positive by the laboratory was qualified as not detected per USEPA Region II validation guidance, due to an associated quality control failure.
UJ	Estimated non-detect - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
UJL	Estimated non-detect (potential low bias) – The analyte was not detected and the report sample quantitation limit is biased low.

VALIDATION SOP

Methyl Mercury

**EDS SOP: Methyl Mercury by CVAFS
USEPA 1630, Rev. 1, 5/14**

METHYLMERCURY VIA METHOD 1630 VALIDATION SOP REVISION 1

SITE:

DATE/INITIALS:

LABORATORY:

Data Completeness and Deliverables

Y N N/A

Have any missing deliverables been received and added to the data package? _____

ACTION: Call lab for explanation/resubmittal of any missing deliverables. If the lab cannot provide them, note the effect on the data review process in the non-compliance section of the data assessment narrative.

Custody Documents and Narratives

Are chains of custody present and complete for all samples? _____

ACTION: Contact lab for replacement of missing documents.

Do chains of custody or lab narratives indicate any problems with sample receipt, condition of samples, analytical problems or special notations affecting the quality of the data? _____

Cooler Temperatures:

ACTION: If samples were not iced/or melted ice is present in the cooler and cooler temperature was outside the range of 4°C (±2) upon receipt, for aqueous and soil, and -15°C (±2) for crab and clam samples note in data assessment narrative. If cooler temperature is found to be in excess of 10°C for aqueous and soil, flag all associated CH₃Hg results as estimated "J."

Holding Times

Have any methyl mercury technical holding times, determined from date of collection to date of preparation and analyses been exceeded (48 hours to preservation, 28 days until analysis)? _____

NOTE: Properly preserved samples may be stable for 6 months, if kept cool and in the dark. However, data qualification will be performed based on the technical holding time for methyl mercury (preservation within 48 hours, analysis within 28 days).

Y N N/A

Aqueous: Samples to be analyzed for methylmercury are shipped to the Laboratory unpreserved in fluoropolymer bottles capped tightly and stored at 4°. Samples must be either preserved or analyzed within 48 hours of collection. Holding time for analysis is 28 days from collection. Soil: No preservatives necessary. Holding time for analysis is 28 days from collection. Clam/Crab Collection: Ziploc® bags and shipped frozen at -15°. Holding time for sample preparation is 60 days. Holding time for analysis is 28 days from the date and time of sample homogenization.

Table of Holding Crab/Crab Collection Time Violations

Sample	Date Collected	Date lab Received	Date of Tissue Preparation
_____	_____	_____	_____
_____	_____	_____	_____

Table of Holding Time Violations

Sample	Sample Matrix	Date Sampled	Date lab Received	Date/Time Preserved	Date/Time Digested	Date/Time Analyzed
_____	_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____	_____

ACTION: If holding times are exceeded, flag all data as estimated "J" for detects and "UJ" for non-detects. If holding times were grossly exceeded (i.e., more than 2x the holding time), flag all positive data as estimated and reject all non-detects as unusable "R".

Sample Preservation

Were the pH values present for aqueous samples? _____

Were samples properly preserved per Section 8.5, Method 1630? _____

Samples may be shipped to the laboratory unpreserved if (1) collected in fluoropolymer bottles (2) filled to the top with no head space (3) Capped tightly and (4) maintained at 0-4°C from the time of collection until preservation. The samples must be acid-preserved within 48 hours of sampling.

NOTE: The pH of all aqueous samples must be tested immediately before aliquotting for processing or direct analysis pH should be < 2.

Preservation samples may be done by adding 5 mL/L of concentrated HCl (to allow both total and methyl Hg determination).

Laboratory Sample Preparation Log

Y N N/A

Are all sample preparation bench sheets and logs present?

Calibration

Are raw data and summary sheets present for the initial calibration?

NOTE: The initial calibration must contain at least 5 points, lowest being at the minimum level (ML) (.06 ng/l) and the analysis of at least *one ethylation blank*. Are the % RSD values for the initial calibration $\leq 15\%$?

ACTION: Associated sample data for those analytes with % RSD > 15 will be qualified as estimated "J". However, if severe discrepancies exist (i.e., %RSD > 50%) validator may elect to reject associated sample results.

Do the ethylation blanks contain positive results > 2 pg?

The net concentration recovery (minus ethylation blank) for the lowest standard must be in the range of 65-135% of the expected value.

ACTION: If the recovery is < 65%, flag associated data as estimated "J" for detects and "R" for non-detects. If the recovery is > 135%, flag associated data "J" for detects.

Are mis-calculations or transcription errors found?

NOTE: If yes, contact the laboratory.

Quality Control Sample (QCS)

Was a QCS analyzed as an independent check of instrument calibration in the analytical batch?

NOTE: The laboratory must obtain QCS source from a different source used to produce the standards, CH₃Hg.

ACTION: If < 50% recovery flag all associated data as "J". If > 150% recovery flag all associated positive data as "J".

Y N N/A

Initial Precision and Recovery (IPR)

Was an initial precision and accuracy demonstration performed for the appropriate matrix per Section 9.2 of Method 1630 (4 replicates of the IPR solution is used to compute an average percent recovery X and the standard deviations of the percent recoveries for CH₃Hg)?

Were the results of the IPR evaluation acceptable when compared to the acceptance limit listed in Table 1 (69-131%)?

ACTION: If IPR data was not provided by the laboratory, contact the lab to obtain the results of the IPR study.

If the result of the laboratories IPR study does not meet the acceptance criteria for performance test listed in Table 1 of Method 1630, contact the laboratory to initiate remediation of technical difficulties. Further sample analyses should not be performed until the laboratory Satisfactorily demonstrates the IPR performance test.

Ongoing Precision and Recovery (OPR)

Was an OPR standard and an ethylation blank prepared and analyzed prior to each sample batch?

Was an OPR analyzed at the end of an analytical run or at the end of each 12- hour shift?

Circle on each OPR summary report percent recoveries outside control limits (67-133%).

Is any OPR recovery:

Less than 10%?

Between 11% and 66%?

Between 134% and 150%?

Greater than 150%?

ACTION: Less than 10%, reject (red-line) all data; between 11% and 66%, flag all associated data as estimated "J"; between 134% and 150%, flag all positive (not flagged with a "U" results as estimated; greater than 150%, reject all positive results.

Blanks

Y N N/A

Method Blank

Has a method blank analysis been reported for each analytical batch not to exceed 20 samples?

NOTE: Three method blanks should accompany each analytical batch. The mean blank value should be used to evaluate associated sample results.

Is the method blank summary present?

Upon evaluation of associated method blank results, do all method blanks meet the MDL criteria listed in Table 1?

ACTION: If the samples associated with the non-compliant method blank contain positive results for methyl mercury which are < 5x that of the mean method blank value, these sample results should be qualified as "U" non-detected. Non-detect results are not affected nor are sample results that are > 5x that of the contaminated method blank mean.

Trip Blank

Has a trip blank analysis been reported for each sample delivery shipment?

Upon examination of the trip blank, does it contain any positive results \geq MDL?

ACTION: If the samples associated with the non-compliant trip blank contain positive results for methyl mercury which are < 5x that of the mean trip blank value, these sample results should be qualified as "U" non-detected. Non-detect results are not affected nor are sample results that are > 5x that of the contaminated trip blank.

Field Blank (For soil samples only. Not applicable for tissue)

Has a field blank analysis been reported for each sampling event not to exceed 20 samples?

Has the field blank been analyzed in the proper sequence?

NOTE: The field blank should be analyzed immediately before analyzing samples in the batch.

Upon examination of the field blank does it contain positive results \geq MDL?

ACTION: If the samples associated with the non-complaint field blank contain positive results for methyl mercury which are < 5x that of the field blank, these sample results should be qualified as "U" non-detected. Non-detect results are not affected nor are sample results that are > 5x that of the contaminated field blank.

Rinse Blank (For tissue sample only. Not applicable for soil)

Y N N/A

Has a rinse blank analysis been reported for each set of decontaminated field equipment?

Upon examination of the rinse blank, does it contain positive its \geq MDL?

ACTION: If the samples associated with the non-complaint rinsate blank contain positive results for methyl mercury which are $< 5x$ that of the rinsate blank, these sample results should be qualified as "U" non-detected. Non-detect results are not affected nor are sample results that are $> 5x$ that of the contaminated rinse blank.

Compound Quantitation and Reported Detection Limits

Verify at least one detected methyl mercury result in each sample delivery group. Recalculate from the raw data to check for calculation and transcription errors.

Were miscalculation/transcription errors found?

ACTION: If errors are found, contact the lab for explanation/re-submittals.

Are all positive methyl mercury results above the MDL reported with:

three significant figures?

correct units (ng/l, ng/kg)?

Field Duplicates

NOTE: To assess the precision and accuracy of the sampling, sample transportation and storage techniques.

The following samples comprise the field duplicate pair: _____

Were field duplicates submitted for methyl mercury analysis at frequency of one per sample delivery group, not to exceed 20?

ACTION: Where both the sample and duplicate values are $> 5x$ the PQL, acceptable sampling and analytical precision is indicated by an RPD for the two field duplicate results of $\leq 20\%$. Where one or both analytes of the field duplicate pair are $< 5x$ the PQL, satisfactory precision is indicated if the field duplicate results agree within $2x$ the PQL. If the above criteria are not met for an analyte, qualify all associated sample data for that analyte as estimated "J".

Matrix Spike/Matrix Spike Duplicate (MS/MSD)

Y N N/A

The following sample was selected for MS/MSD analysis: _____

Is a matrix spike/matrix spike duplicate summary present? _____

Were matrix spikes analyzed at the required frequency for each of the analytical sample groups (i.e., 10% minimum per analytical batch)? _____

ACTION: If any matrix spike data are missing, call the lab for explanation/re-submittal. If information is not available document the effect in narrative notes.

MS/MSD limits for all matrices are as follows:

% Recovery = 65-135%
RPD = ±35%

Have any matrix spike recoveries failed to meet the criteria listed above? _____

Are any spike recoveries:

Less than 10%? _____

Between 10-64%? _____

Between 136-200%? _____

Greater than 200%? _____

ACTION: If < 10%, reject all associated aqueous data; if between 10-64%, flag all associated aqueous data as estimated "JL" or "UJL", potential low bias; if between 136-200%, flag as estimated "J" all associated aqueous data not flagged with a "U"; if > 200%, reject (red-line) all associated aqueous data not flagged with a "U."

Have any MS/MSD relative percent difference values failed to meet the acceptance criteria listed above? _____

ACTION: If any relative percent difference value fails to meet the method acceptance criteria, qualify all associated sample results as estimated "J" for detects or "UJ" for non-detects.

Table 1
Acceptance Criteria For Performance Test

Acceptance Criterion	Section of Method 1630	Limits	Project Quantitation Limit (PQL)
Method Detection Limit		<0.2 ng/L	0.06 ng/L
Initial Precision and Recovery	9.2.		
Precision(s)		+/- 31%	
Recovery (x)		69-131%	
Matrix Spike/Matrix Spike Duplicate	9.3		
Recovery		65-135%	
Relative Percent Difference		+/-35%	
Method Blank	9.4		
Maximum		<2 pg	
Mean		< 0.05 ng/L	
Ongoing Precision and Recovery	9.5	67-133%	

Data Validation Qualifiers

Qualifier	Description
EMPC	Estimated Maximum Possible Concentration (EMPC).
J	Estimated value (bias undetermined) – The analyte was positively identified; but the associated numerical value is the approximate concentration of the analyte in the sample.
JH	Estimated value (potential high bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential high bias, of the analyte in the sample.
JL	Estimated value (potential low bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential low bias, of the analyte in the sample.
M	The analytical result reported was obtained from a sediment sample found to contain between 50 and 90 percent moisture and had no other data qualifiers added during the data validating process.
NJ	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.
R	The sample results are rejected. Due to a significant QA/QC problem, the analysis is invalid and provides no information as to whether the analyte is present or not.
U	Non-detected value – The result initially reported as positive by the laboratory was qualified as not detected per USEPA Region II validation guidance, due to an associated quality control failure.
UJ	Estimated non-detect - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
UJL	Estimated non-detect (potential low bias) – The analyte was not detected and the report sample quantitation limit is biased low.

VALIDATION SOP

Butyltins

EDS SOP: Organotins Prep. 8/05

STANDARD OPERATING PROCEDURE DATA VALIDATION OF ORGANOTIN ANALYSIS

A. INTRODUCTION

This Standard Operating Procedure (SOP) provides guidance for the validation of organotin analytical data generated from the analysis of water, soils, sediments, or tissue samples. The validation procedure was based upon the EPA Region II data validation SOP for Pesticides/PCBs (EPA 1992)¹. A copy of the analytical protocol is provided as an appendix to the QAPP.

B. DATA VALIDATION PROCEDURES

1. Holding Times

Criteria: Holding times are established for both extraction and sample analysis. For aqueous, soil and tissue matrices, the extraction must begin within 7 days from sample collection, with analysis within 40 days of extraction.

Actions: The actions are summarized in Table 1. Actions may be taken for either time from sampling to extraction or time from extraction to analysis, but not both. If neither criteria are met, the exceedance which occurs first (i.e., time to extraction, or the criteria which results in additional qualifications or the "R" qualification takes precedence.

Table 1. Summary of Actions for Holding Times

Time from Sampling to Extraction			
Matrix	0-7 days	7-14 days	> 14 days
Sediment, water and tissues	Accept	"J" positives "UJ" non-detects	"J" positives "R" non-detects
Time from Extraction to Analysis			
Matrix	0-40 days	40-80 days	> 80 days
Sediment, water and tissues	Accept	"J" positives "UJ" non-detects	"J" positives "R" non-detects

2. Initial Calibration

The gas chromatograph undergoes a 5 point initial calibration with all of the targeted analytes. The laboratory may use either a linear regression, or calculate response factors, to ensure proper linear response of the instrument.

Criteria: If linear regression is performed, the laboratory must demonstrate that the regression coefficient ("r") is greater than or equal to 0.995.

If calibration factors are used, the laboratory must demonstrate that the relative standard deviation of the calibration factors is less than 30%.

Actions: The actions are summarized in Table 2.

Table 2. Summary of Actions for Initial Calibration

Initial Calibration using Regression			
Matrix	$R \geq 0.995$	$0.95 < r < 0.995$	$R < 0.95$
Sediment, water and tissues	Accept	"J" positives "UJ" non-detects	"J" positives "R" non-detects
Initial Calibration using Calibration Factors			
Matrix	$RSD < 30\%$	$30\% < RSD < 80\%$	$RSD > 80\%$
Sediment, water and tissues	Accept	"J" positives "UJ" non-detects	"J" positives "R" non-detects

3. Continuing Calibration

The gas chromatograph undergoes a 1 point daily calibration with all of the targeted analytes to ensure consistency with the initial calibration.

Criteria: If linear regression was used for the initial calibration, then the continuing calibration result calculated from the linear regression must agree within 25% of the nominal concentration.

If calibration factors were used for the initial calibration, the laboratory must demonstrate that the percent difference between the mean calibration factors from the continuing calibration and the average response factor from the initial calibration is less than 30%.

Actions: The actions are summarized in Table 3.

Table 3. Summary of Actions for Continuing Calibration

Calibration using Regression			
Matrix	75 – 125% of nominal value	20 – 74% or 126 – 180% of nominal value	< 20% or > 180% of nominal value
Sediment, water and tissues	Accept	"J" positives "UJ" non-detects	"J" positives "R" non-detects
Calibration using Calibration Factors			
Matrix	$\%D < 30\%$	$30\% < \%D < 80\%$	$\%D > 80\%$
Sediment, water and tissues	Accept	"J" positives "UJ" non-detects	"J" positives "R" non-detects

4. Surrogate Recoveries

For soil, water and tissue samples, surrogate is added to the sample extract prior to derivitization.

Criteria: The laboratory must demonstrate that the surrogate recovery falls between 30 and 160%. If the initial analysis fails this criterion, then the samples must be reprocessed once.

Actions: The actions are summarized in Table 4. Chromatograms should be reviewed prior to taking any action to ensure that there were not interferences or coeluting peaks which resulted in the surrogate recoveries falling outside of the control limit. If it is the Reviewer’s professional opinion that the non-compliant surrogate recoveries were due to interferences or co-eluting peaks, no action may be required.

No action is required if the surrogates were diluted out.

Table 4. Summary of Actions for Surrogate Recoveries

	%R < 10%	10 < %R < 30%	30 < %R < 160%	%R > 160%
Positives	“R”	“J”	Accept	“J”
Non-Detects	“R”	“UJ”	Accept	Accept
Note: No action is taken if the surrogates are diluted out.				

5. Method and Field QC Blanks

Method blanks are prepared by the laboratories to identify the potential for laboratory contamination. Field QC blanks are provided by the field team to identify potential contamination by the targeted analytes which may be introduced during field activities.

Criteria: There should be no detected targeted analytes in the method or field QC blanks.

Actions: If the targeted analytes are reported in the method or field QC blanks, and are present at a concentration less than 5 times the blank concentrations in the samples (adjusting for matrix variation and sample size), the reported sample results are potential false-positives and should be qualified with a “U”. No action is taken if the sample concentration is greater than 5 times the method or field QC blank results. Likewise, when associated samples are “not detected” for the analyte, no qualification of data is necessary.

6. Data Calculations and Reported Concentrations

The reported concentrations for the targeted analytes in at least one sample in the Sample Delivery Group should be recalculated and verified. If a discrepancy is noted, the laboratory should be contacted to provide a sample calculation. Corrective actions may be required, as appropriate.

If the laboratory employs a confirmation column to verify sample identifications, it is recommended that the Reviewer verify that the concentrations on both columns are comparable. If significant differences are noted which are attributable to interferences or coeluting peaks, the Reviewer should consider reporting the results from the confirmation column.

7. Sample Moisture Contents

If the sediment samples exhibit moisture contents in excess of 50%, the actions in Table 6 should be taken.

Table 6. Actions for Excessive Moisture Contents in Sediments

	%Moist < 50%	50 < %Moist < 90%	%Moist > 90%
Positives	Accept	"J"	"G"
Non-Detects	Accept	"UJ"	"G"

8. Project Specific Requirements

If the direction of the bias can be determined from the analytical results, then the data reviewer can apply the following data qualifiers:

- Potential high bias: JH or UJ
- Potential low bias: JL or UJL

If the direction of the bias can not be determined, or the assessment of bias is contradicted by the quality control results (e.g., holding time exceedance with high surrogate recoveries), then the overall bias is undetermined, and the "J" or "UJ" qualifiers are appropriate.

YES NO NA
1.0 Traffic Reports and Laboratory Narrative

1.1 Are Traffic Report Forms present for all samples? [] — —

ACTION: If no, contact lab for replacement of missing or illegible copies.

1.2 Do the Traffic Reports or SDG Narrative indicate any problems with sample receipt, condition of the samples, analytical problems or special circumstances affecting the quality of the data? — [] —

ACTION: If any sample analyzed as a soil, other than TCLP, contains 50%-90% water, all data should be qualified as estimated (J). If a soil sample, other than TCLP, contains more than 90% water, all data should be qualified as unusable (R).

ACTION: If samples were not iced (4°C) upon receipt at the laboratory, flag all positive results "J" and all non-detects "UJ".

2.0 Holding Times

2.1 Has the technical holding times, determined from date of sample receipt to date of extraction, been exceeded? — [] —

Note: Samples may be analyzed for herbicide ester and acid. Check Laboratory SDG Narrative.

Note: Aqueous samples must be extracted within 7 days. Extracts must be analyzed within 40 days following extraction. Soil/Concentrated Waste samples must be extracted within 14 days and extracts analyzed within 40 days following extraction.

ACTION: If technical holding times are exceeded, flag all positive results and non-detects(U) as estimated (J) and document in the narrative that holding times were exceeded. Samples extracted more than 28 days from sample receipt, either on the first analysis or upon re-analysis, flag all positive results as estimate ("J") and non-detects as unusable (R).

YES NO NA

3.0 Surrogate Recovery (Form II/Equivalent)

3.1 Are the Herbicide Surrogate Recovery Summaries (Form II/Equivalent) present for each of the following matrices?

- a. Aqueous [] _ _
- b. Soil/Concentrated Waste [] _ _

3.2 Are all the samples listed on the appropriate Surrogate Recovery Summary for each of the following matrices?

- a. Aqueous [] _ _
- b. Soil/Concentrated Waste [] _ _

ACTION: Contact lab for explanation/resubmittals.
 If missing deliverables are unavailable, document effect in data assessments.

3.3 Were outliers marked correctly with an asterisk? [] _ _

ACTION: Circle all outliers with red pencil.

Note: Recommend surrogate is 2,4-Dichlorophenylacetic acid (DCAA)

3.4 Did the laboratory provide their developed in-house QC limits/recoveries? [] _ _

ACTION: If no, use 70 -130% recovery to qualify data

Surrogate Action for Herbicide Analyses

Criteria	Action Detected Target Compounds	Action Non-Detected Target Compounds
% R > 150%	J	No qualification required
70% ≤ % R ≤ 150%	No qualification required	No qualification required
10% ≤ % R < 70%	J	UJ
% R < 10%(Dilution not a factor)	J	R
% R < 10%(Dilution is a factor)	No qualification required	No qualification required

Note: In-house QC limits must be examined for reasonableness, e.g. 10-170% may be appropriate for soil samples but not aqueous samples.

YES NO NA

Note: Matrix effect is suspected if the LCS data are within QC limits but surrogate data exceeds QC limits.

3.5 Were surrogate retention times (RT) within the window established during the initial 5-point calibration analysis?

ACTION: If the RT limits are not met, the analysis may be qualified unusable (R) for that sample on the basis of professional judgment.

3.6 Are there any transcription/calculation errors between the raw data and Form II/Equivalent?

ACTION: If large errors exist, call lab for explanation Or resubmittal. Make any necessary corrections and document effect in the data assessment.

4.0 Laboratory Control Sample

4.1 Are raw data and percent recoveries present for all Laboratory Control samples as required by Method 8000B (section 8.5)

Verify that QC check samples were extracted and analyzed by the same procedures used for the actual samples.

ACTION: If any Laboratory Control Sample data are missing, call the lab for explanation /resubmittals. Make note in the data assessment.

NOTE: For aqueous samples, an additional QC check sample must be prepared and analyzed when any analyte in a matrix spike fails the required acceptance criteria (see section 5.3 below). The additional QC check sample must contain each analyte that failed in the MS analysis.

Note: When the results for matrix spike analysis indicates a problem due to sample matrix effects, the LCS results are used to verify the laboratory can perform the analysis in a clean sample.

4.2 Were Laboratory Control Samples analyzed at the required concentration for all analytes of interest as specified in Method 8000B (sec.8.5)?

ACTION: If Laboratory Control Samples were not analyzed at the required concentration or the required frequency, make note in the data assessment and use professional judgment to determined the affect on the data.

4.3 Were the LCS recoveries within the laboratory's in-house per cent recoveries (if not available, use 70 - 130%)

YES NO NA

4.4 If no, were Laboratory Control Samples re-analyzed?

Note: Corrective action must be taken when one or more of the analytes of interest fail the QC acceptance criteria (Method 8000B, section 8.7.4)

ACTION: If QC check samples were not re-analyzed, or a general system problem is indicated by repeated failure to meet the QC acceptance criteria specified in the method, make note in the data assessment and use professional judgment to determine the effect on the data.

5.0 Matrix Spikes (Form III/Equivalent)

5.1 Is the Matrix Spike/Matrix Spike Duplicate Recovery Form (Form III/Equivalent) present?

5.2 Were matrix spikes analyzed at the required frequency for each of the following matrices?

Note: At a minimum, analysis of at least one matrix spike duplicate unspiked sample or one matrix spike/matrix spike duplicate pair with each batch of up to 20 samples.

a. Aqueous

b. Soil/Concentrated Waste

ACTION: If any matrix spike data are missing, take the action specified in 3.2 above.

5.3 Did the laboratory provide their developed in-house QC limits/recoveries?

ACTION: If no, use 70 -130% recovery to qualify data

ACTION: No action is taken on MS/MSD data alone. However, using informed professional judgment the data reviewer may use the matrix spike results in conjunction with other QC criteria (e.g. LCS) to determine the need for qualification of the data.

6.0 Blanks (Form IV/Equivalent)

6.1 Is the Method Blank Summary (Form IV) present?

YES NO NA

6.2 Frequency of Analysis: has a reagent/method blank been analyzed for each SDG or every 20 samples of similar matrix or concentration or each extraction batch, whichever is more frequent?

ACTION: If any blank data are missing, take the action specified above in 3.2. If blank data is not available, reject "R" all associated positive data. However, using professional judgment, the data reviewer may substitute field blank data for missing method blank data.

6.3 Has a Herbicide instrument blank been analyzed at the beginning of every analytical sequence of 10 samples?

ACTION: If any blank data are missing, call lab for explanation/resubmittals. If missing deliverables are unavailable, document the effect in data assessments.

6.4 Chromatography: review the blank raw data - chromatograms, quant reports or data system printouts.

Is the chromatographic performance (baseline stability) for each instrument acceptable for Herbicides?

ACTION: Use professional judgment to determine the effect on the data.

7.0 Contamination

NOTE: "Water blanks", "distilled water blanks" and drilling water blanks" are validated like any other sample and are not used to qualify the data. Do not confuse them with the other QC

7.1 Do any method/instrument/reagent/cleanup blanks have positive results for Herbicides? When applied as described in the table below, the contaminant concentration in the method blank is multiplied by the sample dilution factor and corrected for % moisture when necessary.

7.2 Do any field/rinse blanks have positive results?

YES NO NA

ACTION: Prepare a list of the samples associated with each of the contaminated blanks. Attach a separate sheet.

NOTE: All field blank results associated to a particular group of samples (may exceed one per case or one per day) may be used to qualify data. Blanks may not be qualified because of contamination in another blank. Field blanks must be qualified for surrogate, calibration, or any QC problems.

ACTION: Follow the directions in the table below to qualify analytes due to contamination. Use the largest value in all the associated blanks.

Action Table for Blank Contamination

Blank Type	Blank Result	Sample Result	Action
Method, Field	Detects	Not detected	No qualification required
	< CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification required
	> CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL and < blank Contamination	Report CRQL value with a U
		≥ CRQL and ≥ blank contamination	No qualification required
	= CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification required
	Gross contamination	Detects	Qualify results as unusable R

NOTE: If gross blank contamination exists (e.g., saturated peaks, "hump-o-grams," "junk" peaks), all affected positive compounds in the associated samples should be qualified as unusable "R", due to interference. Non-detected pesticide target compounds do not require qualification unless the contamination is so high that it interferes with the analyses of non-detected compounds.

7.3 Are there field/rinse/equipment blanks associated with every sample?

ACTION: For low level samples, note in data assessment that there is no associated field/rinse/equipment blank. Exception: samples taken from a drinking water tap do not have associated field blanks.

YES NO NA

8.0 Calibration and GC Performance

8.1 Are the Gas Chromatograms and Data Systems printouts for both columns present for all samples, blanks, QC Check references, and matrix spikes?

ACTION: If no, take action specified in 3.2 above.

8.2 Are Form VI/Equivalent present and complete for each column and each analytical sequence?

ACTION: If no, take action specified in 3.2 above.

8.3 Are there any transcription/calculation errors between raw data and Forms VI?

ACTION: If large errors exist, call lab for explanation Or resubmittal, make necessary corrections and document effect in data assessments.

8.4 Were the retention time windows calculated using the average absolute retention time (at least three measurements + three times the standard deviation of the absolute retention time, for each standard? (Refer to Method 8000A, section 7.5).

8.5. Was a LCS check standard analyzed prior to environmental samples?

8.5.1 If yes, was the surrogate recovery >50%?

8.5.2 Was the LCS check standard re-extracted/re-analyzed, if surrogate recovery was <50%, or any one analyte was < 40%, or two analytes < 70% ?

Action: If No to any of the above, then qualify positive hits as estimated "J" and non-detects as rejected "R" in the original analysis of all samples in the associated analytical sequence.

8.6 Do all standard retention times, including each Hericide in each level of Initial Calibration fall within the windows established during the initial calibration analytical sequence? (For Initial Calibration Standards,

YES NO NA

Form VI/Equivalent - Herbicides - 1).

[] — —

ACTION: If no, all samples in the entire analytical sequence are potentially affected. Check to see if the chromatograms contain peaks within an expanded window surrounding the expected retention times. If no peaks are found and the surrogate is visible, non-detects are valid. If peaks are present and cannot be identified through pattern recognition or using a revised RT window, qualify all positive results and non-detects as unusable (R).

- 8.7 Are the linearity criteria for the Initial Calibration analyses within limits for both columns? (% RSD < 20%) for all analytes).

[] — —

ACTION: If no, qualify all associated positive results generated during the entire analytical sequence "J" and all non-detects "UJ". When RSD > 90%, flag all non-detect results for that analyte R unusable).

- 8.8 Are there any transcription/calculation errors between raw data and Form VII - Herbicides-2?

— [] —

ACTION: If large errors exists, call lab for explanation Or resubmittal, make any necessary corrections and document effect in data assessments.

- 8.9 Is the resolution between any two adjacent peaks in the QC Reference Check Mixture > 60.0% for both columns? (Form VI-Herbicides-4)

[] — —

Note: Formula to compute % Resolution - $\% R = \frac{V}{H} \times 100$

V = Depth of the valley between the peaks of interest and Next eluting peak. The depth of the valley is measured along a vertical line from the level of the apex of the shorter peak to the floor of the valley between the two peaks.

H = Height of the shorter of the adjacent peaks.

ACTION: If no, positive results for compounds that were not adequately resolved should be qualified

YES NO NA

"J". Use professional judgment to determine if non-detects which elute in areas affected by co-eluting peaks should be qualified "JN" as presumptive evidence of presence or unusable (R).

8.10 Is Form VII -Continuing Calibration present and complete for each analytical sequence for both columns?

ACTION: If no, take action as specified in 3.2 above.

8.11 Have all samples been injected within a 24 hr. period beginning with the injection of the first standard?

ACTION: If no, use professional judgment to determine the severity of the effect on the data and qualify accordingly.

8.12 o all analyte retention times for the Mid-concentration Check standard (Form VII Herb-2) fall within the windows established by the initial calibration sequence?

ACTION: If no, beginning with the samples which follows the last in-control standard, check to see if the chromatograms contain peaks within an expanded peaks within an expanded window surrounding retention times. If no peaks are found and surrogates are visible, non-detects are valid. If peaks are present and cannot be identified through pattern recognition or using a revised RT window, qualify all positive results and non-detects as unusable (R).

8.13 Are %Diff values for all verification calibration standard compounds < 25.0%

ACTION: The "associated samples" are those which followed the last in-control standard up to the next passing standard containing the analyte which failed the criteria.

If %Diff > 25, qualify detected compounds "J" and non-detects compounds "UJ"

9.0 Analytical Sequence Check (Form VIII)

- | | YES | NO | NA |
|--|--------------------------|--------------------------|--------------------------|
| 9.1 Is Form VIII present and complete for each column and each period of analyses? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| ACTION: If no, take action specified in 3.2 above. | | | |
| 9.2 Was the proper analytical sequence followed for each initial calibration and subsequent analyses? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| ACTION: If no, use professional judgment to determine the severity of the effect on the data and qualify it accordingly. Generally, the effect is negligible unless the sequence was grossly altered or the or calibration was also out of limits. | | | |
| <u>10.0 Herbicides Identification</u> | | | |
| 10.1 Is Form X complete for every sample in which an Herbicide was detected? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| ACTION: If no, take action specified in 3.2 above. | | | |
| 10.2 Are there any transcription/calculation errors between raw data and Form X. | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| ACTION: If large errors exist, call lab for explanation/resubmittal, make necessary corrections and note errors in data assessment. | | | |
| 10.3 Are retention times (RT) of sample compounds within the established RT windows for both columns? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Was GC/MS confirmation provided instead of confirmation by a second dissimilar column? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Action: Qualify as unusable (R) all positive results which were not confirmed by second GC column analysis or by GC/MS. Also qualify as unusable (R) all positive results not meeting RT window unless associated standard compounds show a similar RT shift. The reviewer should use professional judgment to assign an appropriate quantitation limit. | | | |
| 10.4 Is the percent difference (% D) calculated for the positive sample results on the two GC columns < 25.0%? | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

YES NO NA

ACTION: If the reviewer finds neither column shows interference for the positive hits, Qualify as follows:

<u>% Difference</u>	<u>Qualifier</u>
< 25%	No qualification required
25-50 %	J
50-90 %	JN
> 90 %	R

NOTE: The lower of the two values is reported on Form I. If using professional judgment, the reviewer determines that the higher results was more acceptable, the reviewer should replace the value and indicate the reason for the change in the data assessment.

10.5 Check chromatograms for false negatives. Were there any false negatives? []

ACTION: Use professional judgment to decide if the compound should be reported.

11.0 Compound Quantitation and Reported Detection Limits

11.1 Are there any transcription/calculation errors in Form I results? Check at least two positive values. Were any errors found? []

NOTE: The reviewer should use professional judgment to decide whether a much larger concentration obtained on one column versus the other indicates the presence of an interfering compound. If an interfering compound is indicated, the lower of the two values should be reported and qualified as presumptively present at an approximated quantity (NJ). This necessitates a determination of an estimated concentration on the confirmation column. The narrative should indicate the presence of interferences during the evaluation of the second column confirmation.

11.2 Are the CRQLs adjusted to reflect sample dilutions and, for soils, % moisture? []

ACTION: If errors are large, call lab for explanation resubmittal, make any necessary corrections and document the effect in data assessments.

YES NO NA

ACTION: When a sample is analyzed at more than one dilution, the lowest CRQLs are used (unless a QC exceedance dictates the use of the higher CRQL data from the diluted sample analysis). Replace concentrations that exceed the calibration range in the original analysis by crossing out the "E" value on the original Form I and substituting it with data from the analysis of diluted sample. Specify which Form I is to be used, the draw a red "X" across the entire page of all Form'Is that should not be used, including any in the summary package.

ACTION: Quantitation limits affected by large, off-scale peaks should be qualified as unusable (R). If the interference is on-scale, the reviewer can provide an approximated quantitation limit (UJ) for each affected compound.

11.3 Have all data (Forms and associated chromatograms and quantitation reports) been submitted for original, diluted or re-extraction/re-analysis samples?

12.0 Chromatogram Quality

12.1 Were baselines stable?

12.2 Were any electropositive displacement (negative peaks) or unusual peaks seen?

ACTION: Address comments under System Performance of data assessment. Explain use of professional judgment used to qualify data.

13.0 Field Duplicates

13.1 Were any field duplicates submitted for the Herbicides analysis?

Note: Check whether SAS Client Request required field duplicates.

ACTION: Compare the reported results for field duplicates and calculate the relative percent difference.

ACTION: Any gross variation between field duplicate results

YES NO NA
must be addressed in the reviewer narrative. However,
if large differences exist, identification of field
duplicates should be confirmed by contacting the sampler.

INTRODUCTION

Scope and Applicability

This SOP offers detailed guidance in evaluating laboratory data generated according to "SW846-Method 8270D" January 1998. Method 8270D is used to determine the concentration of semivolatile organic compounds in extracts prepared from many types of solid waste matrices, soils, air sampling media and water samples. The validation methods and actions discussed in this document are based on the requirements set forth in SW846 Method 8270D, Method 8000C and the "USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review," January 2005. This document covers technical problems specific to each fraction and sample matrix; however, situations may arise where data limitations must be assessed based on the reviewer's professional judgement.

Summary of Method

To ensure a thorough evaluation of each result in a data case, the reviewer must complete the checklist within this SOP, answering specific questions while performing the prescribed "ACTIONS" in each section. Qualifiers (or flags) are applied to questionable or unusable results as instructed. The data qualifiers discussed in this document are defined on page 5.

The reviewer must prepare a detailed data assessment to be submitted along with the completed SOP checklist. The Data Assessment must list all data qualifications, reasons for qualifications, instances of missing data and contract non-compliance.

Reviewer Qualifications

Data reviewers must possess a working knowledge of SW846 Analytical Methods and National Functional Guidelines mentioned above.

S))Q

YES NO N/A

DEFINITIONS

Acronyms

- BNA - base neutral acid(another name for Semi Volatiles)
- CLP - Contract Laboratory Program
- CRQL - Contract Required Quantitation Limit
- %D - percent difference
- DCB -decachlorobiphenyl
- DDD - dichlorodiphenyldichloroethane
- DDE - dichlorodiphenylethane
- DDT - dichlorodiphenyltrichloroethane
- DoC - Date of Collection
- GC - gas chromatography
- GC/ECD - gas chromatograph/electron capture detector
- GC/MS - gas chromatograph/mass spectrometer
- GPC - gel permeation chromatography
- IS - internal standard
- kg - kilogram
- µg - microgram
- MS - matrix spike
- MSD - matrix spike duplicate
- ℓ - liter
- mℓ - milliliter
- PCB - Polychlorinated biphenyl
- PE - performance evaluation
- PEM - Performance Evaluation Mixture
- QC - quality control
- RAS - Routine Analytical Services
- RIC - reconstructed ion chromatogram
- RPD - relative percent difference
- RRF - relative response factor
- RRF - average relative response factor (from initial calibration)
- RRT - relative retention time
- RSD - relative standard deviation
- RT - retention time
- RSCC - Regional Sample Control Center
- SDG - sample delivery group
- SMC - system monitoring compound
- SOP - standard operating procedure
- SOW - Statement of Work
- SVOA - semivolatile organic acid
- TCL - Target Compound List
- TCLP - Toxicity Characteristics Leachate Procedure

S))Q

YES NO N/A

- TCX -tetrachloro-m-xylene
- TIC - tentatively identified compound
- TOPO - Task Order Project Officer
- TPO - Technical Project Officer
- VOA - Volatile organic
- VTSR - Validated Time of Sample Receipt

Data Qualifiers

- U - The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
- J - The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
- N - The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."
- JN - The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.
- UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
- R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

LAB QUALIFIERS:

- D - The positive value is the result of an analysis at a secondary dilution factor.
- B - The analyte is present in the associated method blank as well as in the sample. This qualifier has a different meaning when validating inorganic data.

S))Q
YES NO N/A

- E - The concentration of this analyte exceeds the calibration range of the instrument.
- A - Indicates a Tentatively Identified Compound (TIC) is a suspected adol-condensation product.
- X,Y,Z- Laboratory defined flags. The data reviewer must change these qualifiers during validation so that the data user may understand their impact on the data.

I. PACKAGE COMPLETENESS AND DELIVERABLES

CASE NUMBER: _____ LAB: _____
SITE NAME: _____

1.0 Data Completeness and Deliverables

1.1 Has all data been submitted in CLP deliverable format? ___ ___

ACTION: If not, note the effect on review of the data in the data assessment narrative.

2.0 Cover Letter, SDG Narrative

2.1 Is a laboratory narrative or cover letter present? ___ ___

2.2 Are case number and SDG number(s) contained in the narrative or cover letter? ___ ___

II. SEMIVOLATILE ANALYSES

1.0 Traffic Reports and Laboratory Narrative

1.1 Are the Traffic Report Forms present for all samples?

ACTION: If no, contact lab for replacement of missing or illegible copies.

1.2 Do the Traffic Reports or Lab Narrative indicate any problems with sample receipt, condition of samples, analytical problems or special notations affecting the quality of the data?

ACTION: If any sample analyzed as a soil, other than TCLP, contains 50%-90% water, all data should be flagged as estimated ("J"). If a soil sample, other than TCLP, contains more than 90% water, all non-detects data are qualified as unusable (R), and detects are flagged "J".

ACTION: If samples were not iced, or if the ice was melted upon arrival at the laboratory and the cooler temperature was elevated (10°C), flag all positive results "J" and all non-detects "UJ".

2.0 Holding Times

2.1 Have any semivolatile technical holding times, determined from date of collection to date of extraction, been exceeded?

Continuous extraction of water samples for semivolatile analysis must be started within 7 days of the date of collection. Soil/sediment samples must be extracted within 14 days of collection. Extracts must be analyzed within

40 days of the date of extraction.

Table of Holding Time Violations

(See Traffic Report)

Sample ID	Sample Matrix	Date Sampled	Date Lab Received	Date Extracted	Date Analyzed
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____

ACTION: If technical holding times are exceeded, flag all positive results as estimated ("J") and sample quantitation limits as estimated ("UJ"), and document in the narrative that holding times were exceeded.

If analyses were done more than 14 days beyond holding time, either on the first analysis or upon re analysis, the reviewer must use professional judgement to determine the reliability of the data and the effects of additional storage on the sample results. At a minimum, all results should be qualified "J", but the reviewer may determine that non-detect data are unusable ("R"). If holding times are exceeded by more than 28 days, all non-detect data are unusable (R).

YES NO N/A

3.0 Surrogate Recovery (Form II/Equivalent)

3.1 Have the semi volatile surrogate recoveries been listed on CLP Surrogate Recovery forms (Form II) for each of the following matrices:

a. Low Water

b. Low/Med Soil

3.2 If so, are all the samples listed on the appropriate Surrogate Recovery Summary forms for each matrix:

a. Low Water

b. Low/Med Soil

ACTION: If CLP deliverables are unavailable, document the effect(s) in data assessments. In some cases the lab may have to be contacted to obtain the data necessary to complete the validation.

3.3 Were outliers marked correctly with an asterisk?

ACTION: Circle all outliers in red.

3.4 Were two or more base neutral OR acid surrogate recoveries out of specification for any sample or method blank (Reviewer should use lab in house recovery limits. Use surrogate recovery limits from USEPA National Functional Guidelines January 2005 page 130, if in house limits are not available. See Method 8000B-43 or 8000C-24).

Note: Examine lab in house limits for reasonableness.

If yes, were samples re-analyzed?

Were method blanks re-analyzed?

ACTION: If all surrogate recoveries are > 10% but two within the base-neutral or acid fraction do not meet method specifications, for the affected fraction only (i.e. either base-neutral or acid compounds):

1. Flag all positive results as estimated ("J").
2. Flag all non-detects as estimated detection limits ("UJ") when recoveries are less than the lower acceptance limit.
3. If recoveries are greater than the upper acceptance limit, do not qualify non-detects.

If any base-neutral or acid surrogate has a recovery of < 10%:

1. Positive results for the fraction with < 10% surrogate recovery are qualified with "J".
2. Non-detects for that fraction should be qualified as unusable (R) .

NOTE: Professional judgement should be used to qualify data that have method blank surrogate recoveries out of specification in both original and reanalyses. Check the internal standard areas.

3.5 Are there any transcription/calculation errors between raw data and Form II?

ACTION: If large errors exist, call lab for explanation/resubmittal, make any necessary corrections and document

effect in data assessments.

4.0 Matrix Spikes (Form III/Equivalent)

4.1 Have the semivolatle Matrix Spike and Matrix Spike Duplicate/or duplicate unspiked Sample recoveries been listed on the Recovery Form (Form III)?

NOTE: Method 3500B/page 4 states the spiking compounds:

<u>Base/neutrals</u>	<u>Acids</u>
1,2,4-Trichlorobenzene	Pentachlorophenol
Acenaphthene	Phenol
2,4-Dinitrotoluene	2-Chlorophenol
Pyrene	4-Chloro-3-methylphenol
N-Nitroso-di-n-propylamine	4-Nitrophenol
1,4-Dichlorobenzene	

Note: Some projects may require the spiking of specific compounds of interest.

Note: See Method 8270D-sec 8.4.2 for deciding on whether to prepare and analyze duplicate samples or a martix spike/matrix spike duplicate. If samples are expected to contain target analytes, then laboratory may use one matrix spike and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes, laboratory should use a matrix spike and matrix spike duplicate pair.

4.2 Were matrix spikes analyzed at the required frequency for each of the following matrices:

- a. Low Water
- b. Low Solid
- c. Med Solid

ACTION: If any matrix spike data are missing, take the action specified in 3.2 above. It may be necessary to contact the lab to obtain the required data.

NOTE: If the data has not been reported on CLP equivalent form, then the laboratory must provide the information necessary to evaluate the spike recoveries in the MS and MSD. The required data which should have been provided by the lab include the analytes and concentrations used for spiking, background concentrations of the spiked analytes (i.e., concentrations in unspiked sample), methods and equations used to calculate the QC acceptance criteria for the spiked analytes, percent recovery data for all spiked analytes.

The data reviewer must verify that all reported equations and percent recoveries are correct before proceeding to the next section.

4.3 Were matrix spikes performed at concentration equal to 100ug/L for acid compounds, and 200ug/l for base compounds (Method 3500B-4), or those specified in project plan.

4.4 How many semivolatile spike recoveries are outside Laboratory in house MS/MSD recovery limits (use recovery limits values in Method 8270D-43&44 Table 6 if in house values not available).

Water
____ out of ____

Solids
____ out of ____

S))Q

YES NO N/A

4.5 How many RPD's for matrix spike and matrix spike duplicate recoveries are outside QC limits?

Water

Solids

___ out of ___

___ out of ___

ACTION: Circle all outliers with red pencil.

ACTION: No action is taken on MS/MSD data alone. However, using informed professional judgement, the data reviewer may use the matrix spike and matrix spike duplicate results in conjunction with other QC criteria to determine the need for some qualification of the data.

4.6 Was a Laboratory Control Sample (LCS) analyzed with each analytical batch? ___ ___

NOTE: When the results of the matrix spike analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix.

5.0 Blanks (Form IV/Equivalent)

5.1 Is the Method Blank Summary (Form IV) present? ___ ___

5.2 Frequency of Analysis:

Has a reagent/method blank analysis been reported per 20 samples of similar matrix, or concentration level, and for each extraction batch? ___ ___

5.3 Has a method blank been analyzed either after

S))Q
YES NO N/A

the calibration standard or at any other time during the analytical shift for each GC/MS system used ? [] ___ ___

ACTION: If any method blank data are missing, call lab for explanation/resubmittal. If not available, use professional judgement to determine if the associated sample data should be qualified.

5.4 Chromatography: review the blank raw data - chromatograms (RICs), quant reports or data system printouts and spectra.

Is the chromatographic performance (baseline stability) for each instrument acceptable for the semivolatiles? [] ___ ___

ACTION: Use professional judgement to determine the effect on the data.

6.0 Contamination

NOTE: "Water blanks", "drill blanks" and "distilled water blanks" are validated like any other sample and are not used to qualify the data. Do not confuse them with the other QC blanks discussed below.

6.1 Do any method/instrument/reagent blanks have positive results for target analytes and/or TICs? When applied as described below, the contaminant concentration in these blanks are multiplied by the sample dilution factor and corrected for percent moisture where necessary. ___ [] ___

6.2 Do any field/rinse/ blanks have positive results for target analytes and/or TICs (if required, see section 10 below)? ___ [] ___

S))Q

YES NO N/A

ACTION: Prepare a list of the samples associated with each of the contaminated blanks.
(Attach a separate sheet.)

NOTE: All field blank results associated to a particular group of samples (may exceed one per case) must be used to qualify data. Blanks may not be qualified because of contamination in another blank. Field Blanks must be qualified for outlying surrogates, poor spectra, instrument performance or calibration QC problems.

ACTION: Follow the directions in the table below to qualify sample results due to contamination. Use the largest value from all the associated blanks. If gross contamination exists, all data in the associated samples should be qualified as unusable (R).

Blank Action for Semivolatile Analyses

Blank Type	Blank Result	Sample Result	Action for Samples
Method, Field	Detects	Not detected	No qualification required
	< CRQL *	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification required
	= CRQL *	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification required
	> CRQL *	< CRQL	Report CRQL value with a U
		≥ CRQL and < blank contamination	Report concentration of sample with a U
		≥ CRQL and ≥ blank contamination	No qualification required

NOTE: Analytes qualified "U" for blank contamination are still considered as "hits" when qualifying for calibration criteria.

NOTE: If the laboratory did not report TIC analyses, check the project plans to verify whether or not it was required.

6.3 Are there field/rinse/equipment blanks associated with every sample?

ACTION: For low level samples, note in data assessment that there is no associated field/rinse/equipment blank. Exception: samples taken from a drinking water tap do not have associated field blanks.

6.4 Was a instrument blank analyzed after each sample/dilution which contained a target compound

S))Q
YES NO N/A

that exceeded the initial calibration range.

6.5 Does the instrument blank have positive results for target analytes and/or TICs?

Note: Use professional judgement to determine if carryover occurred and qualify analytes accordingly.

7.0 GC/MS Apparatus and Materials

7.1 Did the lab use the proper gas chromatographic column for analysis of semivolatiles by Method 8270D? Check raw data, instrument logs or contact the lab to determine what type of column was used. The method requires the use of 30 m x 0.25 mm ID (or 0.32 mm ID), silicone-coated, fused silica, capillary column.

ACTION: If the specified column, or equivalent, was not used, document the effects in the data assessment. Use professional judgement to determine the acceptability of the data.

8.0 GC/MS Instrument Performance Check (Form V/Equivalent)

8.1 Are the GC/MS Instrument Performance Check Forms (Form V) present for decafluorotriphenylphosphine (DFTPP)?

NOTE: The performance solution should also contain 4,4-DDT, pentachlorophenol, and benzidine to verify injection port inertness and column performance. The degradation of DDT to DDE and DDD must be less than 20% total and the response of pentachlorophenol and benzidine should be within normal ranges for these compounds (based upon lab experience) and show no peak degradation or tailing before samples are analyzed. (see section 5.5

page 8270D-12).

8.2 Are the enhanced bar graph spectrum and mass/charge (m/z) listing for the DFTPP provided for each twelve hour shift? ___ ___

8.3 Has an instrument performance check solution been analyzed for every twelve hours of sample analysis per instrument? ___ ___

ACTION: List date, time, instrument ID, and sample analyses for which no associated GC/MS tuning data are available.

DATE	TIME	INSTRUMENT	SAMPLE NUMBERS
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____

ACTION: If lab cannot provide missing data, reject ("R") all data generated outside an acceptable twelve hour calibration interval.

ACTION: If mass assignment is in error, flag all associated sample data as unusable (R).

8.4 Have the ion abundances been normalized to m/z 198? ___ ___

8.5 Have the ion abundance criteria been met for each instrument used? ___ ___

ACTION: List all data which do not meet ion abundance criteria (attach a separate sheet).

ACTION: If ion abundance criteria are not met, take action specified in section 3.2

8.6 Are there any transcription/calculation errors between mass lists and Form Vs? (Check at least two values but if errors are found, check more.)

8.7 Have the appropriate number of significant figures (two) been reported?

ACTION: If large errors exist, call lab for explanation/resubmittal, make necessary corrections and document effect in data assessments.

8.8 Are the spectra of the mass calibration compound acceptable?

ACTION: Use professional judgement to determine whether associated data should be accepted, qualified, or rejected.

9.0 Target Analytes

9.1 Are the Organic Analysis Data Sheets (Form I) present with required header information on each page, for each of the following:

a. Samples and/or fractions as appropriate

b. Matrix spikes and matrix spike duplicates

c. Blanks

9.2 Has any special cleanup, such as GPC, been performed on all soil/sediment sample extracts (see section 7.2, page 8270D-14)?

S))Q

YES NO N/A

ACTION: If data suggests that extract cleanup was not performed, use professional judgement. Make note in the data assessment narrative.

9.3 Are the Reconstructed Ion Chromatograms, mass spectra for the identified compounds, and the data system printouts (Quant Reports) included in the sample package for each of the following?

- a. Samples and/or fractions as appropriate ___ ___
- b. Matrix spikes and matrix spike duplicates (Mass spectra not required) ___ ___
- c. Blanks ___ ___

ACTION: If any data are missing, take action specified in 3.2 above.

9.4 Are the response factors shown in the Quant Report? ___ ___

- 9.5 Is chromatographic performance acceptable with respect to:
- Baseline stability? ___ ___
 - Resolution? ___ ___
 - Peak shape? ___ ___
 - Full-scale graph (attenuation)? ___ ___
 - Other: _____ ___ ___

ACTION: Use professional judgement to determine the acceptability of the data.

9.6 Are the lab-generated standard mass spectra of identified semivolatiles present for

S))Q
YES NO N/A

each sample?

ACTION: If any mass spectra are missing, take action specified in 3.2 above. If the lab does not generate their own standard spectra, make a note in the data assessment narrative. If spectra are missing, reject all positive data.

9.7 Is the RRT of each reported compound within 0.06 RRT units of the standard RRT in the continuing calibration?

9.8 Are all ions present in the standard mass spectrum at a relative intensity greater than 10% (of the most abundant ion) also present in the sample mass spectrum?

9.9 Do the relative intensities of the characteristic ions in the sample agree within ± 30% of the corresponding relative intensities in the reference spectrum?

ACTION: Use professional judgement to determine acceptability of data. If it is determined that incorrect identifications were made, all such data should be rejected (R), flagged "N" (Presumptive evidence of the presence of the compound) or changed to not detected (U) at the calculated detection limit. In order to be positively identified, the data must comply with the criteria listed in 9.7, 9.8, and 9.9.

ACTION: When sample carry-over is a possibility, professional judgement should be used to determine if instrument cross-contamination has affected any positive compound identification.

10.0 Tentatively Identified Compounds (TIC)

10.1 If Tentatively Identified Compounds were required for this project, are all Form Is, Part B present; and do listed TICs include scan number or retention time, estimated concentration and "JN" qualifier?

NOTE: Review sampling reports to determine if the lab was required to identify non target analytes (refer to section 7.6.2,page 8270D-21).

10.2 Are the mass spectra for the tentatively identified compounds and associated "best match" spectra included in the sample package for each of the following: ___ ___

a. Samples and/or fractions as appropriate ___ ___

b. Blanks ___ ___

ACTION: If any TIC data are missing, take action specified in 3.2 above.

ACTION: Add "JN" qualifier only to analytes identified by CAS #.

10.3 Are any target compounds from one fraction listed as TIC compounds in another (e.g., an acid compound listed as a base neutral TIC)? ___ ___

ACTION: i. Flag with "R" any target compound listed as a TIC.

ii. Make sure all rejected compounds are properly reported in the other fraction.

10.4 Are all ions present in the reference mass spectrum with a relative intensity greater than 10% (of the most abundant ion) also present in the

S)))))))))Q

YES NO N/A

sample mass spectrum?

10.5 Do TIC and "best match" standard relative ion intensities agree within $\pm 20\%$?

ACTION: Use professional judgement to determine acceptability of TIC identifications. If it is determined that an incorrect identification was made, change the identification to "unknown" or to some less specific identification (example: "C3 substituted benzene") as appropriate and remove "JN". Also, when a compound is not found in any blank, but is a suspected artifact of a common laboratory contaminant, the result should be qualified as unusable, "R."

11.0 Compound Quantitation and Reported Detection Limits

11.1 Are there any transcription/calculation errors in Form I results? Check at least two positive values. Verify that the correct internal standard, quantitation ion, and RRF were used to calculate Form I result. Were any errors found?

NOTE: Structural isomers with similar mass spectra, but insufficient GC resolution (i.e. percent valley between the two peaks > 25%) should be reported as isomeric pairs. The reviewer should check the raw data to ensure that all such isomers were included in the quantitation (i.e., add the areas of the two coeluting peaks to calculate the total concentration).

11.2 Are the method detection limits adjusted to reflect sample dilutions and, for soils, sample moisture?

S))Q
YES NO N/A

ACTION: If errors are large, call lab for explanation/resubmittal, make any necessary corrections and document effect in data assessments.

ACTION: When a sample is analyzed at more than one dilution, the lowest detection limits are used (unless a QC exceedance dictates the use of the higher detection limit from the diluted sample data). Replace concentrations that exceed the calibration range in the original analysis by crossing out the "E" and it's associated value on the original Form I (if present) and substituting the data from the analysis of the diluted sample. Specify which Form I is to be used, then draw a red "X" across the entire page of all Form I's that should not be used, including any in the summary package.

12.0 Standards Data (GC/MS)

12.1 Are the Reconstructed Ion Chromatograms, and data system printouts (Quant, Reports) present for initial and continuing calibration? [] ___ ___

ACTION: If any calibration standard data are missing, take action specified in 3.2 above.

13.0 GC/MS Initial Calibration (Form VI/Equivalent)

13.1 Is the Initial Calibration Form (Form VI/Equivalent) present and complete for the semivolatle fraction? [] ___ ___

ACTION: If any calibration forms or standard row data are missing, take action specified in 3.2 above.

13.2 Are all base neutral or acid RRFs > 0.050? [] ___ ___

Check the **average RRFs** of the four System Performance Check Compounds (SPCCs):
N-nitroso-di-n-propylamine, hexachlorocyclopentadiene, 2,4-dinitrophenol, and 4-nitrophenol. These compounds must have **average RRFs** greater than or equal to 0.05 before running samples and should not show any peak tailing.

ACTION: Circle all outliers in red.

ACTION: For any target analyte with **average RRF <0.05**

1. "R" all non-detects;
2. "J" all positive results.

13.3 Are response factors for base neutral or acid target analytes stable over the concentration range of the calibration (% Relative standard deviation [%RSD] < 15.0%)?

NOTE: The % RSD for each individual Calibration Check Compound (CCC, Method 8270D-40 see Table 4) must be less than 30% before analysis can begin. If greater 30%, the lab must clean and recalibrate the instrument.

CALIBRATION CHECK COMPOUNDS

Base/Neutral Fraction	Acid Fraction
Acenaphthene	4-Chloro-3-methylphenol
1,4-Dichlorobenzene	2,4-Dichlorophenol
Hexachlorobutadiene	2-Nitrophenol
Diphenylamine	Phenol
Di-n-octyl phthalate	Pentachlorophenol
Fluoranthene	2,4,6-Trichlorophenol

Benzo(a)pyrene

ACTION: If the %RSD for any CCC >30% and no corrective action taken, then "J" qualify all positive hits and "UJ" qualify all non-detects.

ACTION: Circle all outliers in red.

ACTION: If the % RSD is $\geq 15.0\%$, qualify positive results for that analyte "J" and non-detects using professional judgement. When RSD > 90%, flag all non- detect results for that analyte "R," unusable. Alternatively, the lab should calculate first or second order regression fit of the calibration curve and select the fit which introduces the least amount of error.

NOTE: Analytes previously qualified "U" due to blank contamination are still considered as "hits" when qualifying for calibration criteria.

13.4 Did the laboratory calculate the calibration curve by the least squares regression fit?

13.5 Are there any transcription/calculation errors in the reporting of average response factors (RRF) or % RSD? (Check at least two values but if errors are found, check more.)

ACTION: Circle Errors in red.

ACTION: If errors are large, call lab for explanation/resubmittal, make any necessary corrections and note errors in data assessments.

13.5 Do the target compounds for this SDG include Pesticides?

13.6 If the pesticide compounds include DDT, was the percent breakdown of DDT to DDD and DDE greater than 20%?

- ACTION: If DDT percent breakdown exceeds 20%:
- i. Qualify all positive results for DDT with "J". If DDT was not detected, but DDD and DDE results are positive, qualify the quantitation limit for DDT as unusable, "R".
 - ii. Qualify all positive results for DDD and DDE as presumptively present at an approximate concentration "JN".

14.0 GC/MS Calibration Verification (Form VII/Equivalent)

14.1 Are the Calibration Verification Forms (Form VII) present and complete for all compounds of interest?

14.2 Has a calibration verification standard been analyzed for every twelve hours of sample analysis per instrument?

ACTION: List below all sample analyses that were not within twelve hours of a calibration verification analysis for each instrument used.

ACTION: If any forms are missing or no calibration verification standard has been analyzed within twelve hours of every sample analysis,

call lab for explanation/resubmittal. If continuing calibration data are not available, flag all associated sample data as unusable ("R").

14.3 Do any of the SPCCs have an RRF <0.05? _____ _____

If YES, make a note in data assessment if the lab did not take corrective action specified in section 7.4.4, page 8270D-18. _____ _____

14.4 Do any of the CCCs have a %D between the initial and continuing RRF which exceeds 20.0%?

ACTION: If yes, make a note in data assessment.

14.5 Do any semivolatile compounds have a % Difference (% D) between the initial and continuing RRF which exceeds 20.0%? _____ _____

ACTION: Circle all outliers in red.

ACTION: Qualify both positive results and non-detects for the outlier compound(s) as estimated (J). When %D is above 90%, qualify all non-detects for that analyte as "R", unusable.

14.6 Do any semivolatile compounds have a RRF < 0.05? _____ _____

ACTION: Circle all outliers in red.

ACTION: If RRF < 0.05, qualify as unusable ("R") associated non-detects and "J" associated positive values.

14.7 Are there any transcription/calculation errors in the reporting of average response factors (RRF) or percent difference (%D) between initial and continuing RRFs? (Check at least two values but if errors are found, check more). _____ _____

ACTION: Circle errors in red.

ACTION: If errors are large, call lab for explanation/resubmittal, make any necessary corrections and document effect(s) in the data assessments.

15.0 Internal Standards (Form VIII)

15.1 Are the internal standard areas (Form VIII) of every sample and blank within the upper and lower limits (-50% to + 100%) for each continuing calibration?

— —

ACTION: List each outlying internal standard below.

Sample ID	IS #	Area	LowerLimit	Upper Limit
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____

(Attach additional sheets if necessary.)

Note: Check Table 5, 8270D-41 for associated analytes.

- ACTION:
- i. If the internal standard area count is outside the upper or lower limit, flag with "J" all positive results and non-detects (U values) quantitated with this internal standard.
 - ii. Non-detects associated with IS > 100% should not be qualified.

S))Q

YES NO N/A

iii. If the IS area is below the lower limit (<50%), qualify all associated non-detects (U-values) "J". If extremely low area counts are reported (<25%) or if performance exhibits a major abrupt drop off, flag all associated non-detects as unusable (R).

15.2 Are the retention times of all internal standards within 30 seconds of the associated calibration standard?

ACTION: Professional judgement should be used to qualify data if the retention times differ by more than 30 seconds.

16.0 Laboratory Control Samples (LCS)

16.1 Were any LCS samples run in order to verify analytes which failed criteria for spike recovery?

16.2 Did the lab spike LCS sample spiked with the same analytes and the same concentrations as the matrix spike?

16.3 Were the mean and standard deviation of all analytes within the QC acceptance ranges as shown in Table 6, 8270D-43?

ACTION: If the recovery of any analyte falls out of the designated range, the analytical results for that compound is suspect and should be qualified "J" in the unspiked samples.

17.0 Field Duplicates

17.1 Were any field duplicates submitted for semivolatile analysis?

S))Q

YES NO N/A

ACTION: Compare the reported results for field duplicates and calculate the relative percent difference.

ACTION: Any gross variation between field duplicate results must be addressed in the reviewer narrative. However, if large differences exist, identification of field duplicates should be confirmed by contacting the sampler.

INTRODUCTION

This document is designed to offer the data reviewer guidance in determining the validity of analytical data generated through the USEPA Contract Laboratory Program (CLP) Statement of Work (SOW) for Multi-Media, Multi-Concentration Organics Analysis (SOM01.2), and any future editorial revisions of SOM01.2, hereinafter referred to as the SOM01.2 SOW. This guidance is somewhat limited in scope and is intended to be used as an aid in the formal technical review process.

The guidelines presented in the document will aid the data reviewer in establishing (a) if data meets the specific technical and QC criteria established in the SOW, and (b) the validity and extent of bias of any data not meeting the specific technical and QC criteria established in the SOW. It must be understood by the reviewer that acceptance of data not meeting technical requirements is based upon many factors, including, but not limited to site-specific technical requirements, the need to facilitate the progress of specific projects, and availability for re-sampling.

The reviewer should note that while this document is to be used as an aid in the formal data review process, other sources of guidance and information, as well as **professional judgment**, should also be used to determine the ultimate validity of data, especially in those cases where all data does not meet specific technical criteria.

DATA QUALIFIER DEFINITIONS

The following definitions provide brief explanations of the national qualifiers assigned to results in the data review process.

U	The analyte was analyzed for, but was not detected above the level of the reported sample quantitation limit.
J	The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.
J+	The result is an estimated quantity, but the result may be biased high.
J-	The result is an estimated quantity, but the result may be biased low.
NJ	The analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.
UJ	The analyte was analyzed for, but was not detected. The reported quantitation limit is approximate and may be inaccurate or imprecise.
R	The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.

DATA PACKAGE INSPECTION

For data obtained through the Contract Laboratory Program (CLP), the EXES Data Manager (EDM) is a useful tool in the data review process. For more information about EDM, please refer to the following Sample Management Office (SMO) website:

<https://epasmoweb.fedcsc.com/help/guides/Submit%20and%20Inspect%20Data%20Quick%20Guide%20%28EXES%29.pdf>

EDM will identify any missing and/or incorrect information in the data package. The CLP laboratory may submit a reconciliation package for any missing items or to correct data. If there are any concerns regarding the data package, contact the CLP Project Officer (CLP PO) from the Region where the samples were taken. For personnel contact information, please refer to the following CLP website:

<http://www.epa.gov/superfund/programs/clp/contacts.htm>

HWSS DATA VALIDATION PROCESS

After downloading the data package from EDM, the data validator will use the recommendations in this SOP as well as their own professional judgment to validate the data.

The data will be saved in the following location, under the appropriate case number folder:

G:\DESADIV\HWSS\DATA VALIDATION

The file naming conventions will consist of

- | | |
|----------------------------------|-------------|
| A. case number | i.e., 12345 |
| B. SDG name | i.e., BXY12 |
| C. level of validation performed | i.e., S3VE |

Examples: **12345_BXY12_S3VE.xls**

12345_BXY12_S3VEM.xls

When data validation is completed, the data package is uploaded for the client to download from the HWSS data delivery website:

<https://epaqpx.rtp.epa.gov/hwssclpdeliverables>

The completed data package includes the Executive Narrative (see Appendix B for template), the Sample Summary Report (see Appendix C for example), and the Electronic Data Deliverable (EDD) (see Appendix D for a list of the column headers included in this document).

PRELIMINARY REVIEW

This document is for the review of analytical data generated through the SOM01.2 SOW and any future editorial revisions of SOM01.2 for USEPA Region 2. To use this document effectively, the reviewer should have an understanding of the analytical method and a general overview of the Sample Delivery Group (SDG) or sample Case at hand. The exact number of samples, their assigned numbers, their matrix, and the number of laboratories involved in the analysis are essential information.

It is suggested that an initial review of the data package be performed, taking into consideration all information specific to the sample data package [e.g., Modified Analysis requests, Traffic Report/Chain of Custody (TR/COC) documentation, SDG Narratives, etc.].

The reviewer should also have a copy of the Quality Assurance Project Plan (QAPP) or similar document for the project for which the samples were analyzed. The criteria for data validation outlined in the QAPP supersede this Standard Operating Procedure. The reviewer should contact the appropriate Regional Contract Laboratory Program Project Officer (CLP PO) to obtain copies of the QAPP and relevant site information. This information is necessary in determining the final usability of the analytical data.

The SDGs or Cases routinely have unique samples that require special attention from the reviewer. These include field blanks and trip blanks, field duplicates, and Performance Evaluation (PE) samples which must be identified in the sampling records. The sampling records (e.g., TR/COC records, field logs, and/or contractor tables) should identify:

1. The Region where the samples were taken,
2. The Case number,
3. The complete list of samples with information on:
 - a. Sample matrix;
 - b. Field blanks (i.e., equipment blanks or rinsate blanks) and trip blanks;
 - c. Field duplicates;
 - d. Field spikes;
 - e. QC audit samples;
 - f. Shipping dates;
 - g. Preservatives; and
 - h. Laboratories involved.

The TR/COC documentation includes sample descriptions and date(s) of sampling. The reviewer must consider lag times between sampling and start of analysis when assessing technical sample holding times.

The laboratory's SDG Narrative is another source of general information. Notable problems with matrices, insufficient sample volume for analysis or reanalysis, samples received in broken containers, preservation, and unusual events should be documented in the SDG Narrative. The reviewer should also inspect any email or telephone/communication logs detailing any discussion of sample or analysis issues between the laboratory, the CLP Sample Management Office (SMO), and USEPA Region 2.

Preservation

Action:

1. Qualify aqueous sample results using preservation and technical holding time information as follows (see Table 1):
 - a. If there is no evidence that the samples were properly preserved ($T = 4^{\circ}\text{C} \pm 2^{\circ}\text{C}$), and the samples were extracted or analyzed within the technical holding times [seven (7) days from sample collection for extraction; 40 days from sample collection for analysis], qualify detects as estimated (J) and non-detects as estimated (UJ).
 - b. If there is no evidence that the samples were properly preserved ($T = 4^{\circ}\text{C} \pm 2^{\circ}\text{C}$), and the samples were extracted or analyzed outside the technical holding times [seven (7) days from sample collection for extraction; 40 days from sample collection for analysis], qualify detects as estimated (J) and non-detects as estimated (UJ).
 - c. If the samples were properly preserved, and were extracted and analyzed within the technical holding times [seven (7) days from sample collection for extraction; 40 days from sample collection for analysis], no qualification of the data is necessary.
 - d. If the samples were properly preserved, and were extracted or analyzed outside the technical holding times [seven (7) days from sample collection for extraction; 40 days from sample collection for analysis], qualify detects as estimated (J) and non-detects as estimated (UJ). Note in the Data Review Narrative that holding times were exceeded and the effect of exceeding the holding time on the resulting data.
2. Qualify non-aqueous sample results using preservation and technical holding time information as follows (see Table 1):
 - a. If there is no evidence that the samples were properly preserved ($T = 4^{\circ}\text{C} \pm 2^{\circ}\text{C}$), and the samples were extracted or analyzed within the technical holding time [14 days from sample collection for extraction; 40 days from sample collection for analysis], qualify detects as estimated (J) and non-detects as estimated (UJ).
 - b. If there is no evidence that the samples were properly preserved ($T = 4^{\circ}\text{C} \pm 2^{\circ}\text{C}$), and the samples were extracted or analyzed outside the technical holding time [14 days from sample collection for extraction; 40 days from sample collection for analysis], qualify detects as estimated (J) and non-detects as estimated (UJ).
 - c. If the samples were properly preserved, and were extracted and analyzed within the technical holding time [14 days from sample collection for extraction; 40 days from sample collection for analysis], no qualification of the data is necessary.
 - d. If the samples were properly preserved, and were extracted or analyzed outside the technical holding time [14 days from sample collection for

extraction; 40 days from sample collection for analysis], qualify detects as estimated (J) and non-detects as estimated (UJ). Note in the Data Review Narrative that holding times were exceeded and the effect of exceeding the holding time on the resulting data.

3. Whenever possible, the reviewer should comment on the effect of the holding time exceedance on the resulting data in the Data Review Narrative.
4. Use professional judgment to qualify samples whose temperature upon receipt at the laboratory is either below 2 degrees centigrade or above 6 degrees centigrade.
5. If technical holding times are grossly exceeded, use professional judgment to qualify the data.
6. Note, for Contract Laboratory Program Project Officer (CLP PO) action, when technical holding times are exceeded.

Table 1. Holding Time Actions for Semivolatile Analyses

Matrix	Preserved	Criteria	Action	
			Detected Associated Compounds	Non-Detected Associated Compounds
Aqueous	No	≤ 7 days (for extraction) ≤ 40 days (for analysis)	J	UJ
	No	> 7 days (for extraction) > 40 days (for analysis)	J	UJ
	Yes	≤ 7 days (for extraction) ≤ 40 days (for analysis)	No qualification	
	Yes	> 7 days (for extraction) > 40 days (for analysis)	J	UJ
	Yes/No	Grossly Exceeded	Use professional judgment	
Non-Aqueous	No	≤ 14 days (for extraction) ≤ 40 days (for analysis)	J	UJ
	No	> 14 days (for extraction) > 40 days (for analysis)	J	UJ
	Yes	≤ 14 days (for extraction) ≤ 40 days (for analysis)	No qualification	
	Yes	> 14 days (for extraction) > 40 days (for analysis)	J	UJ
	Yes/No	Grossly Exceeded	Use professional judgment	

Gas Chromatograph/Mass Spectrometer (GC/MS) Instrument Performance Check

Action:

NOTES: These requirements do not apply when samples are analyzed by the Selected Ion Monitoring (SIM) technique.

All mass spectrometer instrument conditions must be identical to those used during the sample analysis. Background subtraction actions resulting in spectral distortions for the sole purpose of meeting the method specifications are contrary to the Quality Assurance (QA) objectives, and are therefore unacceptable.

NOTES: No data should be qualified based on DFTPP failure. Instances of this should be noted in the narrative.

All ion abundance ratios must be normalized to m/z 198, the nominal base peak, even though the ion abundance of m/z 442 may be up to 100% that of m/z 198.

The requirement to analyze the instrument performance check solution is optional when analysis of Polycyclic Aromatic Hydrocarbon (PAH)/pentachlorophenol is to be performed by the Selected Ion Monitoring (SIM) technique.

1. If samples are analyzed without a preceding valid instrument performance check or are analyzed 12 hours after the Instrument Performance Check, qualify all data in those samples as unusable (R).
2. If the laboratory has made minor transcription errors which do not significantly affect the data, the data reviewer should make the necessary corrections on a copy of the form.
3. If the laboratory has failed to provide the correct forms or has made significant transcription or calculation errors, the Region's designated representative should contact the laboratory and request corrected data. If the information is not available, the reviewer must use professional judgment to assess the data. Notify the laboratory's Contract Laboratory Program Project Officer (CLP PO).
4. If ion abundance criteria are not met, use professional judgment to determine to what extent the data may be utilized. Guidelines to aid in the application of professional judgment in evaluating ion abundance criteria are discussed as follows:
 - a. Some of the most critical factors in the DFTPP criteria are the non-instrument specific requirements that are also not unduly affected by the location of the spectrum on the chromatographic profile. The m/z ratios for 198/199 and 442/443 are critical. These ratios are based on the natural abundances of carbon 12 and carbon 13 and should always be met. Similarly, the relative abundances for m/z 68, 70, 197, and 441 indicate the condition of the instrument and the suitability of the resolution adjustment. Note that all of the foregoing abundances relate to adjacent ions; they are relatively insensitive to differences in instrument design and position of the spectrum on the chromatographic profile.
 - b. For the ions at m/z 51, 127, and 275, the actual relative abundance is not as critical. For instance, if m/z 275 has 80.0% relative abundance (criteria: 10.0-60.0%) and other criteria are met, the deficiency is minor.

- c. The relative abundance of m/z 365 is an indicator of suitable instrument zero adjustment. If relative abundance for m/z 365 is zero, minimum detection limits may be affected. On the other hand, if m/z 365 is present, but less than the 0.75% minimum abundance criteria, the deficiency is not as serious.
5. Note, in the Data Review Narrative, decisions to use analytical data associated with DFTPP instrument performance checks not meeting contract requirements.
6. If the reviewer has reason to believe that instrument performance check criteria were achieved using techniques other than those described in Semivolatiles Organic Analysis, Section II.D.5 of the SOM1.2 NFG, obtain additional information on the instrument performance checks. If the techniques employed are found to be at variance with the contract requirements, the performance and procedures of the laboratory may merit evaluation. Note, for CLP PO action, concerns or questions regarding laboratory performance. For example, if the reviewer has reason to believe that an inappropriate technique was used to obtain background subtraction (such as background subtracting from the solvent front or from another region of the chromatogram rather than from the DFTPP peak), note this for CLP PO action.
7. Use professional judgment to determine whether associated data should be qualified based on the spectrum of the mass calibration compound.

Initial Calibration

Table 2. Semivolatile Target Compounds Exhibiting Poor Response

Compounds	
2,2'-Oxybis-(1-chloropropane)	Benzaldehyde
4-Chloroaniline	4-Nitroaniline
Hexachlorobutadiene	4,6-Dinitro-2-methylphenol
Hexachlorocyclopentadiene	N-Nitrosodiphenylamine
2-Nitroaniline	3-3'-Dichlorobenzidine
3-Nitroaniline	1,1'-Biphenyl
2,4-Dinitrophenol	Dimethylphthalate
4-Nitrophenol	Diethylphthalate
Acetophenone	1,2,4,5-Tetrachlorobenzene
Caprolactam	Carbazole
Atrazine	Butylbenzylphthalate
Di-n-butylphthalate	Di-n-octylphthalate
Bis(2-ethylhexyl)phthalate	

Action:

NOTES: The twenty-five (25) poor performing compounds are listed in Table 2 above. The relative response factor (RRF) for these compounds must be greater than or equal to 0.010. The RRF for all other semivolatile target compounds must be ≥ 0.050 . Analytes previously qualified as non-detected (U) for blank contamination are still treated as "hits" when qualifying for initial calibration criteria. If analysis by Selected Ion Monitoring (SIM) technique is requested for PAHs/pentachlorophenols, calibration standards are analyzed at 0.10, 0.20, 0.40, 0.80, and 1.0 ng/ μ L for each target compound of interest and the associated DMCs. Pentachlorophenol will require only a four-point initial calibration at 0.20, 0.40, 0.80, and 1.0 ng/ μ L

1. Qualify all semivolatile target compounds, including the compounds exhibiting poor response listed in Table 2, using the following criteria (see Table 3):
 - a. If any semivolatile target compound has an RRF value less than the minimum criterion (0.010 for the compounds exhibiting poor response listed in Table 2, and 0.050 for all other semivolatile compounds), use professional judgment for detects, based on mass spectral identification, to qualify the data as estimated (J).
 - b. If any semivolatile target compound has an RRF value less than the minimum criterion (0.010 for the compounds exhibiting poor response listed in Table 2, and 0.050 for all other semivolatile compounds), qualify non-detected compounds as unusable (R).

- c. If any of the semivolatile target compounds listed in Table 2 has %RSD greater than 40.0%, qualify detects as estimated (J), and non-detected compounds using professional judgment (see Action 2).
 - d. For all other semivolatile target compounds, if %RSD is greater than 20.0%, qualify detects as estimated (J), and non-detected compounds using professional judgment (see Action 2).
 - e. If the semivolatile target compounds meet the acceptance criteria for RRF and the %RSD, no qualification of the data is necessary.
 - f. No qualification of the data is necessary on the DMC RRF and %RSD data alone. Use professional judgment and follow the guidelines in Action 2 to evaluate the DMC RRF and %RSD data in conjunction with the DMC recoveries to determine the need for qualification of data.
2. At the reviewer's discretion, and based on the project-specific Data Quality Objectives (DQOs), a more in-depth review may be considered using the following guidelines:
- a. If any semivolatile target compound has a %RSD greater than the maximum criterion (40.0% for the compounds listed in Table 2, and 20.0% for all other semivolatile compounds), and if eliminating either the high or the low-point of the curve does not restore the %RSD to less than or equal to the required maximum:
 - i. Qualify detects for that compound(s) as estimated (J).
 - ii. Qualify non-detected semivolatile target compounds using professional judgment.
 - b. If the high-point of the curve is outside of the linearity criteria (e.g., due to saturation):
 - i. Qualify detects outside of the linear portion of the curve as estimated (J).
 - ii. No qualifiers are required for detects in the linear portion of the curve.
 - iii. No qualifiers are required for semivolatile target compounds that were not detected.
 - c. If the low-point of the curve is outside of the linearity criteria:
 - i. Qualify low-level detects in the area of non-linearity as estimated (J).
 - ii. No qualifiers are required for detects in the linear portion of the curve.
 - iii. For non-detected semivolatile compounds, use the lowest point of the linear portion of the curve to determine the new quantitation limit.
3. If the laboratory has failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
4. Document in the Data Assessment Report the analytes that fail %RSD and/or RRF criteria.
5. Note in the Data Review Narrative, whenever possible, the potential effects on the data due to calibration criteria exceedance.
6. Note, for Contract Laboratory Program Project Officer (CLP PO) action, if calibration criteria are grossly exceeded.

Table 3. Initial Calibration Actions for Semivolatiles Analyses

Criteria	Action	
	Detected Associated Compounds	Non-Detected Associated Compounds
RRF < 0.010 (target compounds listed in Table 2) RRF < 0.050 (all other target compounds)	J (based on mass spectral identification)	R
RRF ≥ 0.010 (target compounds listed in Table 2) RRF ≥ 0.050 (all other target compounds)	No qualification	
% RSD ≤ 40.0 (target compounds listed in Table 2) % RSD ≤ 20.0 (all other target compounds)	No qualification	
% RSD > 40.0 (target compounds listed in Table 2) % RSD > 20.0 (all other target compounds)	J	Use professional judgment

Continuing Calibration Verification (CCV)

Action:

NOTES: Verify that the CCV was run at the required frequency (an opening and closing CCV must be run within 12-hour period) and the CCV was compared to the correct initial calibration. If the mid-point standard from the initial calibration is used as an opening CCV, verify that the result (RRF) of the mid-point standard was compared to the average RRF from the correct initial calibration. The closing CCV used to bracket the end of a 12-hour analytical sequence may be used as the opening CCV for the new 12-hour analytical sequence, provided that all the technical acceptance criteria are met for an opening CCV (see Table 4 below). If the closing CCV does not meet the technical acceptance criteria for an opening CCV, then a DFTPP tune followed by an opening CCV is required and the next 12-hour time period begins with the DFTPP tune. All DMCs must meet $RRF \geq 0.010$. No qualification of the data is necessary on the DMCs RRF and %RSD/%D data alone. However, use professional judgment to evaluate the DMC and %RSD/%D data in conjunction with the DMC recoveries to determine the need of qualification the data.

1. If a CCV (opening and closing) was not run at the appropriate frequency, qualify data using professional judgment.
2. Qualify all semivolatile target compounds, including the compounds exhibiting poor response listed in Table 2 using the following criteria:
 - a. For an opening CCV, if any semivolatile target compound has an RRF value less than the minimum criterion (0.010 for the compounds exhibiting poor response, and 0.050 for all other semivolatile compounds), use professional judgment for detects, based on mass spectral identification, to qualify detects as estimated (J) and qualify non-detected compounds as unusable (R).
 - b. For a closing CCV, if any semivolatile target compound has an RRF value less than 0.010, use professional judgment for detects based on mass spectral identification to qualify detects as estimated (J), and qualify non-detected compounds as unusable (R).
 - c. For an opening CCV, if the Percent Difference value for any of the semivolatile target compounds listed in Table 2 is outside the $\pm 40.0\%$ criterion, qualify detects as estimated (J) and non-detected compounds as estimated (UJ).
 - d. For an opening CCV, if the Percent Difference value for any other semivolatile target compound is outside the $\pm 25.0\%$ criterion, qualify detects as estimated (J) and non-detected compounds as estimated (UJ).
 - e. For a closing CCV, if the Percent Difference value for any semivolatile target compound is outside the $\pm 50.0\%$ criterion, qualify detects as estimated (J) and non-detected compounds as estimated (UJ).
 - f. If the semivolatile target compounds meet the acceptable criteria for RRF and the Percent Difference, no qualification of the data is necessary.

- g. No qualification of the data is necessary on the DMC RRF and the Percent Difference data alone. Use professional judgment to evaluate the DMC RRF and Percent Difference data in conjunction with the DMC recoveries to determine the need for qualification of data.
- 3. If the laboratory has failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
- 4. Document in the Data Assessment under Contract Problems/Non-Compliance if more than two of the required analytes failed the acceptance criteria in Table 4.
- 5. Note in the Data Review Narrative, whenever possible, the potential effects on the data due to calibration criteria exceedance.
- 6. Note, for Contract Laboratory Program Project Officer (CLP PO) action, if calibration criteria are grossly exceeded.

Table 4. Continuing Calibration Verification (CCV) Actions for Semivolatile Analyses

Criteria for Opening CCV	Criteria for Closing CCV	Action	
		Detected Associated Compounds	Non-Detected Associated Compounds
RRF < 0.010 (semivolatile target compounds listed in Table 2) RRF < 0.050 (all other semivolatile target compounds)	RRF < 0.010 (all semivolatile target compounds)	J (based on mass spectral identification)	R
RRF ≥ 0.010 (semivolatile target compounds listed in Table 2) RRF ≥ 0.050 (all other semivolatile target compounds)	RRF ≥ 0.010 (all semivolatile target compounds)	No qualification	
%D > 40.0 or < -40.0 (semivolatile target compounds listed in Table 2) %D > 25.0 or < -25.0 (all other semivolatile target compounds)	%D > 50.0 or < -50.0 (all semivolatile target compounds)	J	UJ
%D ≤ 40.0 and ≥ -40.0 (semivolatile target compounds listed in Table 2) %D ≤ 25.0 and ≥ -25.0 (all other semivolatile target compounds)	%D ≤ 50.0 and ≥ -50.0 (all semivolatile target compounds)	No qualification	

Blanks

Action:

NOTES: The concentration of non-target compounds in all blanks must be less than or equal to 10 µg/L.
The concentration of each target compound found in the method or field blanks must be less than its CRQL listed in the method, except bis(2-ethylhexyl)phthalate, which must be less than 5x its respective CRQL in low-level samples.

Data concerning the field blanks are not evaluated as part of the CCS process. If field blanks are present, the data reviewer should evaluate this data in a similar fashion as the method blanks.

NOTES: “Water blanks, “drill blanks”, and “distilled water blanks” are validated like any other sample and are not used to qualify data. Do not confuse them with the other QC blanks discussed below.

All field blank results associated with a particular group of samples (may exceed one per case) must be used to qualify data. Blanks may not be qualified because of contamination in another blank. Field blanks must be qualified for system monitoring compounds, instrument performance criteria, and spectral or calibration QC problems.

Samples taken from a drinking water tap do not have associated field blanks. When applied as described in Table 5 below, the contaminant concentration in the blank is multiplied by the sample dilution factor.

Action regarding unsuitable blank results depends on the circumstances and origin of the blank. In instances where more than one of the same type of blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of a contaminant. Do not correct the results by subtracting any blank value.

1. If a semivolatile compound is found in a method blank, but not found in the sample, no qualification of the data is necessary (see Table 5).
2. If the method or field blanks contain a semivolatile Target Compound List (TCL) compound(s) at a concentration less than the CRQL (less than 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples) and:
 - a. the sample concentration is less than the CRQL (less than 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples), report the CRQL value with a “U”.
 - b. the sample concentration is greater than or equal to the CRQL (greater than or equal to 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples), no qualification is required.
3. If the method or field blanks contain a semivolatile TCL compound(s) at a concentration greater than the CRQL (greater than 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples) and:

- a. the sample concentration is less than the CRQL (less than 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples), report the CRQL value with a “U”.
 - b. the sample concentration is greater than or equal to the CRQL (greater than or equal to 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples), and less than or equal to the blank concentration, report the concentration of the compound in the sample at the same concentration found in the blank and qualify with a “U”.
 - c. the sample concentration is greater than or equal to the CRQL (greater than or equal to 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples) and greater than the blank concentration, no qualification is required.
4. If the method or field blanks contain a semivolatile TCL compound(s) at a concentration equal to the CRQL (equal to 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples) and:
 - a. the sample concentration is less than or equal to the CRQL (less than or equal to 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples), report the CRQL value with a “U”.
 - b. the sample concentration is greater than the CRQL (greater than 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples), no qualification is required.
 5. If gross contamination exists (i.e., saturated peaks by GC/MS) in the method or field blanks, raise the CRQL to the level of the blank contamination and report the associated sample data below this level as CRQL-U. Non-detected semivolatile target compounds do not require qualification unless the contamination is so high that it interferes with the analyses of non-detected compounds.
 6. If contaminants are found in the field blanks, the following is recommended:
 - a. Review the associated method blank data to determine if the contaminant(s) was also present in the method blank.
 - i. If the analyte was present at a comparable level in the method blank, the source of the contamination may be in the analytical system and the action recommended for the method blank would apply.
 - ii. If the analyte was not present in the method blank, the source of contamination may be in the storage area, in the field, or during sample transport. Consider all associated samples for possible cross-contamination.
 7. Tentatively Identified Compounds (TICs) should only be considered if requested.
 - a. For TICs, if the concentration in the sample is less than five times the concentration in the most contaminated associated blank (TIC concentration < 5xblank concentration), qualify the sample data as unusable (R).
 8. If method blank data are unavailable, the reviewer may use professional judgment or substitute field blank data for missing method blank data.

NOTE: There may be instances where little or no contamination was present in the associated blanks, but qualification of the sample is deemed necessary. If the reviewer determines that the contamination is from a source other than the sample, they should qualify the data. Contamination introduced through dilution water is one example. Although it is not always possible to determine, instances of this occurring can be detected when contaminants are found in the diluted sample result, but are absent in the undiluted sample result.

Table 5. Blank Actions for Semivolatiles Analyses

Blank Type	Blank Result	Sample Result	Action for Samples
Method, Field	Detects	Not detected	No qualification required
	< CRQL *	< CRQL*	Report CRQL value with a U
		≥ CRQL*	No qualification required
	> CRQL *	< CRQL*	Report CRQL value with a U
		≥ CRQL* and ≤ blank concentration	Report blank value for sample concentration with a U
		≥ CRQL* and > blank concentration	No qualification required
	= CRQL*	≤ CRQL*	Report CRQL value with a U
		> CRQL*	No qualification required
Gross contamination	Detects	Report blank value for sample concentration with a U	

* 5x the CRQL for bis(2-ethylhexyl)phthalate in low-level samples.

Deuterated Monitoring Compounds (DMCs)

Table 6. Semivolatile Deuterated Monitoring Compounds (DMCs) and Recovery Limits

DMC	Recovery Limits (%) for Water Samples	Recovery Limits (%) for Soil/Sediment Samples
Phenol-d ₅	39 – 106	17 – 103
Bis-(2-chloroethyl) ether-d ₈	40 – 105	12 – 98
2-Chlorophenol-d ₄	41 – 106	13 – 101
4-Methylphenol-d ₈	25 – 111	8 – 100
Nitrobenzene-d ₅	43 – 108	16 – 103
2-Nitrophenol-d ₄	40 – 108	16 – 104
2,4-Dichlorophenol-d ₃	37 – 105	23 – 104
4-Chloroaniline-d ₄	1 – 145	1 – 145
Dimethylphthalate-d ₆	47 – 114	43 – 111
Acenaphthylene-d ₈	41 – 107	20 – 97
4-Nitrophenol-d ₄	33 – 116	16 – 166
Fluorene-d ₁₀	42 – 111	40 – 108
4,6-Dinitro-2-methylphenol-d ₂	22 – 104	1 – 121
Anthracene-d ₁₀	44 – 110	22 – 98
Pyrene-d ₁₀	52 – 119	51 – 120
Benzo(a)pyrene-d ₁₂	32 – 121	43 – 111
Fluoranthene-d ₁₀ (SIM)	50 – 150	50 – 150
2-Methylnaphthalene-d ₁₀ (SIM)	50 – 150	50 – 150

Action:

NOTES: Recoveries for DMCs in semivolatile samples and blanks must be within the limits specified in Table 6.

The recovery limits for any of the compounds listed in Table 6 may be expanded at any time during the period of performance if USEPA determines that the limits are too restrictive.

NOTE: Up to four (4) DMCs per sample may fail to meet the recovery limits, but all recoveries must be > 0%. As per SOM01.2, any sample which has more than 4 DMCs outside the limits must be reanalyzed.

Table 8 lists the semivolatile DMCs and their associated target compounds. If **any** DMC recovery in the semivolatiles fraction is out of specification, qualify the data considering the existence of interference in the raw data (see Table 7). Considerations include, but are not limited to:

1. For any recovery greater than the upper acceptance limit:
 - a. Qualify detected associated semivolatile target compounds as estimated high (J+).
 - b. Do not qualify non-detected associated semivolatile target compounds.
2. For any recovery less than the lower acceptance limit:

- a. Qualify detected associated semivolatile target compounds as estimated low (J-).
- b. Qualify non-detected associated semivolatile target compounds as estimated (UJ).
3. For any recovery within acceptance limits, no qualification of the data is necessary.
4. In the special case of a blank analysis having DMCs out of specification, the reviewer must give special consideration to the validity of associated sample data. The basic concern is whether the blank problems represent an isolated problem with the blank alone, or whether there is a fundamental problem with the analytical process. For example, if one or more samples in the batch show acceptable DMC recoveries, the reviewer may choose to consider the blank problem to be an isolated occurrence. However, even if this judgment allows some use of the affected data, note analytical problems for Contract Laboratory Program Project Officer (CLP PO) action.
5. If more than four DMCs are outside of the recovery limits for semivolatiles analysis and the sample was not reanalyzed, note under Contract Problems/Non-Compliance.

Table 7. Deuterated Monitoring Compound (DMC) Recovery Actions for Semivolatiles Analyses

Criteria	Action	
	Detected Associated Compounds	Non-detected Associated Compounds
%R > Upper Acceptance Limit	J+	No qualification
%R < Lower Acceptance Limit	J-	UJ
Lower Acceptance Limit ≤ %R ≤ Upper Acceptance Limit	No qualification	

Table 8. Semivolatile Deuterated Monitoring Compounds (DMCs) and the Associated Target Compounds

Phenol-d₅	2-Chlorophenol-d₄	2-Nitrophenol-d₄
Benzaldehyde Phenol	2-Chlorophenol	Isophorone 2-Nitrophenol
bis(2-Chloroethyl) ether-d₈	4-Methylphenol-d₈	4-Chloroaniline-d₄
bis-(2-Chloroethyl) ether 2,2'-oxybis(1-Chloropropane) bis(2-Chloroethoxy) methane	2-Methylphenol 4-Methylphenol 2,4-Dimethylphenol	4-Chloroaniline Hexachlorocyclopentadiene 3,3'-Dichlorobenzidine
Nitrobenzene-d₅	2,4-Dichlorophenol-d₃	Dimethylphthalate-d₆
Acetophenone N-Nitroso-di-n-propylamine Hexachloroethane Nitrobenzene 2,6-Dinitrotoluene 2,4-Dinitrotoluene N-Nitrosodiphenylamine	2,4-Dichlorophenol Hexachlorobutadiene 4-Chloro-3-methylphenol 2,4,6-Trichlorophenol 2,4,5-Trichlorophenol 1,2,4,5-Tetrachlorobenzene Pentachlorophenol 2,3,4,6-Tetrachlorophenol	Caprolactam 1,1'-Biphenyl Dimethylphthalate Diethylphthalate Di-n-butylphthalate Butylbenzylphthalate bis(2-ethylhexyl)phthalate Di-n-octylphthalate
Fluorene-d₁₀	Anthracene-d₁₀	Pyrene-d₁₀
Dibenzofuran Fluorene 4-Chlorophenyl-phenylether 4-Bromophenyl-phenylether Carbazole	Hexachlorobenzene Atrazine Phenanthrene Anthracene	Fluoranthene Pyrene Benzo(a)anthracene Chrysene
Acenaphthylene-d₈	4-Nitrophenol-d₄	Benzo (a) pyrene-d₁₂
Naphthalene 2-Methylnaphthalene 2-Chloronaphthalene Acenaphthylene Acenaphthene	2-Nitroaniline 3-Nitroaniline 2,4-Dinitrophenol 4-Nitrophenol 4-Nitroaniline	Benzo(b)fluoranthene Benzo(k)fluoranthene Benzo(a)pyrene Indeno(1,2,3-cd)pyrene Dibenzo(a,h)anthracene Benzo(g,h,i)perylene
4,6-Dinitro-2-methylphenol-d₂	Fluoranthene-d₁₀ (SIM)	2-Methylnaphthalene-d₁₀ (SIM)
4,6-Dinitro-2-methylphenol	Fluoranthene Pyrene Benzo(a)anthracene Chrysene Benzo(b)fluoranthene Benzo(k)fluoranthene Benzo(a)pyrene Indeno(1,2,3-cd)pyrene Dibenzo(a,h)anthracene Benzo(g,h,i)perylene	Napthalene 2-Methylnaphthalene Acenaphthylene Acenaphthene Fluorene Pentachlorophenol Phenathrene Anthracene

Matrix Spike/Matrix Spike Duplicates (MS/MSDs)

Action:

NOTES: Data for MS and MSDs will not be present unless requested by the Region. Notify the Contract Laboratory Program Project Officer (CLP PO) if a field blank was used for the MS and MSD.

NOTE: For a Matrix Spike that does not meet criteria, apply the action to only the field sample used to prepare the Matrix Spike sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

1. No qualification of the data is necessary on MS and MSD data alone. However, using professional judgment, the validator may use the MS and MSD results in conjunction with other QC criteria and determine the need for some qualification of the data.

Internal Standards

Action:

1. If an internal standard area count for a sample or blank is greater than 200.0% of the area for the associated standard (opening CCV or mid-point standard from initial calibration) (see Table 9):
 - a. Qualify detects for compounds quantitated using that internal standard as estimated low (J-).
 - b. Do not qualify non-detected associated compounds.
2. If an internal standard area count for a sample or blank is less than 50.0% of the area for the associated standard (opening CCV or mid-point standard from initial calibration):
 - a. Qualify detects for compounds quantitated using that internal standard as estimated high (J+).
 - b. Qualify non-detected associated compounds as unusable (R).
3. If an internal standard area count for a sample or blank is greater than or equal to 50.0%, and less than or equal to 200% of the area for the associated standard opening CCV or mid-point standard from initial calibration, no qualification of the data is necessary.
4. Absolute RTs of internal standards should not vary dramatically between samples and the associated 12-hour calibration standard (opening CCV or mid-point standard from the initial calibration). If an internal standard RT varies by more than 30.0 seconds: Examine the chromatographic profile for that sample to determine if any false positives or negatives exist. For shifts of a large magnitude, the reviewer may consider partial or total rejection of the data for that sample fraction. Detects should not need to be qualified as unusable (R) if the mass spectral criteria are met.
5. If an internal standard RT varies by less than or equal to 30.0 seconds, no qualification of the data is necessary.
6. Note, for Contract Laboratory Program Project Officer (CLP PO) action, if the internal standard performance criteria are grossly exceeded. Note in the Data Review Narrative potential effects on the data resulting from unacceptable internal standard performance.

Table 9. Internal Standard Actions for Semivolatiles Analyses

Criteria	Action	
	Detected Associated Compounds*	Non-detected Associated Compounds*
Area counts > 200% of 12-hour standard (opening CCV or mid-point standard from initial calibration)	J-	No qualification
Area counts < 50% of 12-hour standard (opening CCV or mid-point standard from initial calibration)	J+	R
Area counts \geq 50% but \leq 200% of 12-hour standard (opening CCV or mid-point standard from initial calibration)	No qualification	
RT difference > 30.0 seconds between samples and 12-hour standard (opening CCV or mid-point standard from initial calibration)	R	
RT difference \leq 30.0 seconds between samples and 12-hour standard (opening CCV or mid-point standard from initial calibration)	No qualification	

* For semivolatile compounds associated to each internal standard, see Table 2 - Semivolatile Target Compounds and Deuterated Monitoring Compounds with Corresponding Internal Standards for Quantitation in **SOM01.2, Exhibit D**, available at: <http://www.epa.gov/superfund/programs/clp/som1.htm>

Standards Data

Action:

If missing deliverables are unavailable, document the effect in the Data Assessment.

Target Compound Identification

Criteria:

1. The Relative Retention Times (RRTs) of reported compounds must be within ± 0.06 RRT units of the standard RRT [opening Continuing Calibration Verification (CCV) or mid-point standard from the initial calibration].
2. Mass spectra of the sample compound and a current laboratory-generated standard [i.e., the mass spectrum from the associated calibration standard (opening CCV or mid-point standard from initial calibration)] must match according to the following criteria:
 - a. All ions present in the standard mass spectrum at a relative intensity greater than 10% must be present in the sample spectrum.
 - b. The relative intensities of these ions must agree within $\pm 20\%$ between the standard and sample spectra (e.g., for an ion with an abundance of 50% in the standard spectrum, the corresponding sample ion abundance must be between 30-70%).
 - c. Ions present at greater than 10% in the sample mass spectrum, but not present in the standard spectrum, must be evaluated by a reviewer experienced in mass spectral interpretation.

Action:

1. The application of qualitative criteria for GC/MS analysis of target compounds requires professional judgment. It is up to the reviewer's discretion to obtain additional information from the laboratory. If it is determined that incorrect identifications were made, qualify all such data as unusable (R).
2. Use professional judgment to qualify the data if it is determined that cross-contamination has occurred.
3. Note in the Data Review Narrative any changes made to the reported compounds or concerns regarding target compound identifications. Note, for Contract Laboratory Program Project Officer (CLP PO) action, the necessity for numerous or significant changes.

Tentatively Identified Compounds (TICs)

Action:

NOTE: Tentatively identified compounds should only be evaluated when requested by a party from outside of the Hazardous Waste Support Section (HWSS).

1. Qualify all TIC results for which there is presumptive evidence of a match (e.g. greater than or equal to 85% match) as tentatively identified (NJ), with approximated concentrations. TICs labeled “unknown” are qualified as estimated (J).
2. General actions related to the review of TIC results are as follows:
 - a. If it is determined that a tentative identification of a non-target compound is unacceptable, change the tentative identification to “unknown” or another appropriate identification, and qualify the result as estimated (J).
 - b. If all contractually-required peaks were not library searched and quantitated, the Region’s designated representative may request these data from the laboratory.
3. In deciding whether a library search result for a TIC represents a reasonable identification, use professional judgment. If there is more than one possible match, report the result as “either compound X or compound Y”. If there is a lack of isomer specificity, change the TIC result to a nonspecific isomer result (e.g., 1,3,5-trimethyl benzene to trimethyl benzene isomer) or to a compound class (e.g., 2-methyl, 3-ethyl benzene to a substituted aromatic compound).
4. The reviewer may elect to report all similar compounds as a total (e.g., all alkanes may be summarized and reported as total hydrocarbons).
5. Target compounds from other fractions and suspected laboratory contaminants should be marked as “non-reportable”.
6. Other Case factors may influence TIC judgments. If a sample TIC match is poor, but other samples have a TIC with a valid library match, similar RRT, and the same ions, infer identification information from the other sample TIC results.
7. Note in the Data Review Narrative any changes made to the reported data or any concerns regarding TIC identifications.
8. Note, for Contract Laboratory Program Project Officer (CLP PO) action, failure to properly evaluate and report TICs

Compound Quantitation and Reported Contract Required Quantitation Limits (CRQLs)

Action:

1. When a sample is analyzed at more than one dilution, the lowest CRQLs are used unless a QC exceedance dictates the use of the higher CRQLs from the diluted sample. Replace concentrations that exceed the calibration range in the original analysis by crossing out the “E” and its corresponding value on the original Form I and substituting the data from the diluted sample.
2. If any discrepancies are found, the Region's designated representative may contact the laboratory to obtain additional information that could resolve any differences. If a discrepancy remains unresolved, the reviewer must use professional judgment to decide which value is the most accurate. Under these circumstances, the reviewer may determine that qualification of data is warranted. Note in the Data Review Narrative a description of the reasons for data qualification and the qualification that is applied to the data.
3. For non-aqueous samples, if the percent moisture is less than 70.0%, no qualification of the data is necessary. If the percent moisture is greater than or equal to 70.0% and less than 90.0%, qualify detects as estimated (J) and non-detects as approximated (UJ). If the percent moisture is greater than or equal to 90.0%, qualify detects as estimated (J) and non-detects as unusable (R) (see Table 10).
4. Note, for Contract Laboratory Program Project Officer (CLP PO) action, numerous or significant failures to accurately quantify the target compounds or to properly evaluate and adjust CRQLs.

Table 10. Percent Moisture Actions for Semivolatiles Analysis For Non-Aqueous Samples

Criteria	Action	
	Detected Associated Compounds	Non-detected Associated Compounds
% Moisture < 70.0	No qualification	
70.0 < % Moisture < 90.0	J	UJ
% Moisture > 90.0	J	R

Field Duplicates

Action:

NOTE: In the absence of QAPP guidance for validating data from field duplicates, the following action will be taken.

Identify which samples within the data package are field duplicates. Estimate the relative percent difference (RPD) between the values for each compound. Use professional judgment to note large RPDs (> 50%) in the narrative.

System Performance

Action:

Use professional judgment to qualify the data if it is determined that system performance has degraded during sample analyses. Note, for Contract Laboratory Program Project Officer (CLP PO) action, any degradation of system performance which significantly affected the data.

Overall Assessment of Data

Action:

1. Use professional judgment to determine if there is any need to qualify data which were not qualified based on the Quality Control (QC) criteria previously discussed.
2. Write a brief narrative to give the user an indication of the analytical limitations of the data. Note, for Contract Laboratory Program Project Officer (CLP PO) action, any inconsistency of the data with the Sample Delivery Group (SDG) Narrative. If sufficient information on the intended use and required quality of the data is available, the reviewer should include their assessment of the usability of the data within the given context. This may be used as part of a formal Data Quality Assessment (DQA).

APPENDIX A: GLOSSARY

Analyte -- The element of interest, ion, or parameter an analysis seeks to determine.

Analytical Services Branch (ASB) -- Directs the Contract Laboratory Program (CLP) from within the Office of Superfund Remediation and Technical Innovation (OSRTI) in the Office of Solid Waste and Emergency Response (OSWER).

Analytical Sample -- Any solution or media introduced into an instrument on which an analysis is performed excluding instrument calibration, Initial Calibration Verification (ICV), Initial Calibration Blank (ICB), Continuing Calibration Verification (CCV), and Continuing Calibration Blank (CCB). Note that the following are all defined as analytical samples: undiluted and diluted samples (USEPA and non-USEPA); Matrix Spike samples; duplicate samples; serial dilution samples, analytical (post-digestion/post-distillation) spike samples; Interference Check Samples (ICSs); Laboratory Control Samples (LCSs); and Preparation Blanks.

Associated Samples -- Any sample related to a particular Quality Control (QC) analysis. For example, for Initial Calibration Verification (ICV), all samples run under the same calibration curve. For duplicates, all Sample Delivery Group (SDG) samples digested/distilled of the same matrix.

Blank -- A sample designed to assess specific sources of contamination. See individual definitions for types of blanks.

Calibration -- The establishment of an analytical curve based on the absorbance, emission intensity, or other measured characteristic of known standards. The calibration standards are to be prepared using the same type of reagents or concentration of acids as used in the sample preparation.

Calibration Blank -- A blank solution containing all of the reagents in the same concentration as those used in the analytical sample preparation. This blank is not subject to the preparation method.

Calibration Curve -- A plot of instrument response versus concentration of standards.

Calibration Standards -- A series of known standard solutions used by the analyst for calibration of the instrument (i.e., preparation of the analytical curve). The solutions may or may not be subjected to the preparation method, but contain the same matrix (i.e., the same amount of reagents and/or preservatives) as the sample preparations to be analyzed.

Case -- A finite, usually predetermined number of samples collected over a given time period from a particular site. Case numbers are assigned by the Sample Management Office (SMO). A Case consists of one or more Sample Delivery Groups (SDGs).

Contract Compliance Screening (CCS) -- A screening of electronic and hardcopy data deliverables for completeness and compliance with the contract. This screening is performed under USEPA direction by the Contract Laboratory Program (CLP) Sample Management Office (SMO) contractor.

Continuing Calibration Verification (CCV) -- A single parameter or multi-parameter standard solution prepared by the analyst and used to verify the stability of the instrument calibration with time, and the instrument performance during the analysis of samples. The CCV can be one of the calibration standards. However, all parameters being measured by the particular system must be represented in this standard and the standard must have the same matrix (i.e., the same amount of reagents and/or preservatives) as the samples.

Contract Laboratory Program (CLP) -- Supports the USEPA's Superfund effort by providing a range of state-of-the-art chemical analytical services of known quality. This program is directed by the Analytical Services Branch (ASB) of the Office of Superfund Remediation and Technical Innovation (OSRTI) of USEPA.

Contract Laboratory Program Project Officer (CLP PO) -- The Regional USEPA official responsible for monitoring laboratory performance and/or requesting analytical data or services from a CLP laboratory.

Contract Required Quantitation Limit (CRQL) -- Minimum level of quantitation acceptable under the contract Statement of Work (SOW).

Duplicate -- A second aliquot of a sample that is treated the same as the original sample in order to determine the precision of the method.

Field Blank -- Any sample that is submitted from the field and identified as a blank. A field blank is used to check for cross-contamination during sample collection, sample shipment, and in the laboratory. A field blank includes trip blanks, rinsate blanks, bottle blanks, equipment blanks, preservative blanks, decontamination blanks, etc.

Field Duplicate -- A duplicate sample generated in the field, not in the laboratory.

Holding Time -- The maximum amount of time samples may be held before they are processed.

Contractual -- The maximum amount of time that the Contract Laboratory Program (CLP) laboratory may hold the samples from the sample receipt date until analysis and still be in compliance with the terms of the contract, as specified in the CLP Analytical Services Statement of Work (SOW). These times are the same or less than technical holding times to allow for sample packaging and shipping.

Technical -- The maximum amount of time that samples may be held from the collection date until analysis.

Initial Calibration -- Analysis of analytical standards for a series of different specified concentrations to define the quantitative response, linearity, and dynamic range of the instrument to target analytes.

Initial Calibration Verification (ICV) -- Solution(s) prepared from stock standard solutions, metals, or salts obtained from a source separate from that utilized to prepare the calibration standards. The ICV is used to verify the concentration of the calibration standards and the adequacy of the instrument calibration. The ICV should be traceable to National Institute of Standards and Technology (NIST) or other certified standard sources when USEPA ICV solutions are not available.

Internal Standard -- A non-target element added to a sample at a known concentration after preparation but prior to analysis. Instrument responses to internal standards are monitored as a means of assessing overall instrument performance.

Matrix -- The predominant material of which the sample to be analyzed is composed. For the purposes of this document, the matrices are aqueous/water, soil/sediment, wipe, and filter.

Matrix Spike -- Introduction of a known concentration of analyte into a sample to provide information about the effect of the sample matrix on the digestion and measurement methodology (also identified as a pre-distillation/digestion spike).

Method Detection Limit (MDL) -- The concentration of a target parameter that, when a sample is processed through the complete method, produces a signal with 99 percent probability that it is different from the blank. For 7 replicates of the sample, the mean value must be 3.14s above the blank, where "s" is the standard deviation of the 7 replicates.

Narrative (SDG Narrative) -- Portion of the data package which includes laboratory, contract, Case, Sample Number identification, and descriptive documentation of any problems encountered in processing the samples, along with corrective action taken and problem resolution.

Office of Solid Waste and Emergency Response (OSWER) -- The USEPA office that provides policy, guidance, and direction for the USEPA's solid waste and emergency response programs, including Superfund.

Percent Difference (%D) -- As used in this document and the Statement of Work (SOW), is used to compare two values. The difference between the two values divided by one of the values.

Performance Evaluation (PE) Sample -- A sample of known composition provided by USEPA for contractor analysis. Used by USEPA to evaluate Contractor performance.

Preparation Blank -- An analytical control that contains reagent water and reagents, which is carried through the entire preparation and analytical procedure.

Relative Percent Difference (RPD) -- As used in this document and the Statement of Work (SOW) to compare two values, the RPD is based on the mean of the two values, and is reported as an absolute value (i.e., always expressed as a positive number or zero).

Regional Sample Control Center Coordinator (RSCC) -- In USEPA Regions, coordinates sampling efforts and serves as the central point-of-contact for sampling questions and problems. Also assists in coordinating the level of Regional sampling activities to correspond with the monthly projected demand for analytical services.

Relative Standard Deviation (RSD) -- As used in this document and the Statement of Work (SOW), the mean divided by the standard deviation, expressed as a percentage.

Sample -- A single, discrete portion of material to be analyzed, which is contained in single or multiple containers and identified by a unique Sample Number.

Sample Delivery Group (SDG) -- A unit within a sample Case that is used to identify a group of samples for delivery. An SDG is defined by the following, whichever is most frequent:

- a. Each 20 field samples [excluding Performance Evaluation (PE) samples] within a Case; or
- b. Each 7 calendar day period (3 calendar day period for 7-day turnaround) during which field samples in a Case are received (said period beginning with the receipt of the first sample in the SDG).
- c. Scheduled at the same level of deliverable.

In addition, all samples and/or sample fractions assigned to an SDG must be scheduled under the same contractual turnaround time. Preliminary Results have **no impact** on defining the SDG.

Samples may be assigned to SDGs by matrix (i.e., all soil/sediment samples in one SDG, all aqueous/water samples in another) at the discretion of the laboratory.

Sample Management Office (SMO) -- A contractor-operated facility operated under the SMO contract, awarded and administered by the USEPA. Provides necessary management, operations, and administrative support to the Contract Laboratory Program (CLP).

Statement of Work (SOW) -- A document which specifies how laboratories analyze samples under a particular Contract Laboratory Program (CLP) analytical program.

Information

Initiator Name: Elizabeth Melenbrink Date of Initiation: 8 May 2013

Department Name: HWSS SOP Number: HW-35 Revision Number: 2

SOP Title: Semivolatile Data Validation

Major Revision

Minor Revision

Change(s) (Use attachment if necessary):

Add to the section **HWSS DATA VALIDATION PROCESS:**

All data is initially marked as "reportable" (Y) in EDM before validation is begun. Sometimes, due to dilutions, re-analyses, or SIM/scan runs all being performed, there will be multiple results for a single analyte from a single sample. The following criteria and professional judgment are used to determine which result should be reported:

- The analysis with the lower CRQL
- The analysis with the better QC results
- The analysis with the higher result

The analyte values and their respective CRQLs are then transferred into a single sample run. The runs that are not to be used are updated as "not reportable" or (N) in EDM.

Reason(s) for change(s):

These circumstances were not addressed in this version of the SOP.

INTRODUCTION

Scope and Applicability

This SOP offers detailed guidance in evaluating laboratory data generated according to the method in the "USEPA Contract Laboratory Program Statement of Work for Organics Analysis Multi-Media, Multi-Concentration, SOM01.1, May 2005". The validation procedures and actions discussed in this document are based on the requirements set forth in the "USEPA Contract Laboratory Program National Functional Guidelines for Superfund Organic Methods Data Review, January 2005". This document attempts to cover technical problems specific to low/Medium concentration of Aroclor compounds. Situations may arise where data limitations must be assessed based on the reviewer's own professional judgement.

In addition to technical requirements, contractual requirements may also be covered in this document. While it is important that instances of contract non-compliance be addressed in the Data Assessment, the technical criteria are always used to qualify the analytical data.

Summary

To ensure a thorough evaluation of each result in a data case, the reviewer must complete the checklist within this SOP, answering specific questions while performing the prescribed "ACTIONS" in each section. Qualifiers (or flags) are applied to questionable or unusable results as instructed. The data qualifiers discussed in this document are as follows:

Data Qualifiers

- U - The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
- J - The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
- N - The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."
- JN - The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate

concentration.

- UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
- R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Lab Qualifiers:

- D - The positive value is the result of an analysis at a secondary dilution factor.
- B - The analyte is present in the associated method blank as well as in the sample. This qualifier has a different meaning when validating inorganic data.
- E - The concentration of this analyte exceeds the calibration range of the instrument.
- P - Aroclor target analytes when the % Difference between the analyte concentrations obtained from the two dissimilar GC columns is greater than 25%.
- C - This flag applies to Aroclors results when the identification has been confirmed by GC/MS analysis.
- S - Single point calibration.

The reviewer must prepare a detailed data assessment to be submitted along with the completed SOP checklist. The Data Assessment must list all data qualifications, reasons for qualifications, instances of missing data and contract non-compliance.

Reviewer Qualifications:

Data reviewers must possess a working knowledge of the USEPA Statement of Work SOM01.2 and National Functional Guidelines mentioned above.

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

PACKAGE COMPLETENESS AND DELIVERABLES

CASE NUMBER: _____ LAB: _____

SITE NAME: _____ SDG No(s) .: _____

1.0 Chain of Custody and Sampling Trip Reports

1.1 Are the Traffic Reports/Chain-of-Custody Records present for all samples? ___ ___

ACTION: If no, contact RSCC, or the TOPO to obtain replacement of missing or illegible copies from the lab.

1.2 Is the Sampling Trip Report present for all samples? ___ ___

ACTION: If no, contact either RSCC or ask the TOPO to obtain the necessary information from the prime contractor.

2.0 Data Completeness and Deliverables

2.1 Have any missing deliverables been received and added to the data package? ___ ___

ACTION: Contact the TOPO to obtain an explanation or resubmittal of any missing deliverables from the lab. If lab cannot provide them, note the effect on the review of the data package in the Contract

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

Problems/Non-compliance section of the Data Assessment.

- 2.2 Was SMO/CLASS CCS checklist included with the package?
- 2.3 Are there any discrepancies between the Traffic Reports/Chain-of-Custody Records, and Sampling Trip Report?

ACTION: If yes, contact the TOPO to obtain an explanation or resubmittal of any missing deliverables from the laboratory.

3.0 Cover Letter SDG Narrative

- 3.1 Is the SDG Narrative or Cover Letter Present?
- 3.2 Are case number, SDG number and contract number contained in the SDG Narrative or cover letter (see SOW, Exhibit B, section 2.5.1)?
EPA sample numbers in the SDG, detailed documentation of any quality control, sample, shipment, and/or analytical problems encountered in processing the samples? Corrective action taken?
- 3.3 Does the Narrative contain the following information SOM01.1, page B-12, section 2.5.1)?
column used, storage of samples, case#, SDG#, analytical problems, and discrepancies between field and lab weights.
- 3.5 Did the contractor record the temperature of the cooler on the Form DC-1, Item 9 - Cooler Temperature, and in the SDG Narrative?
- 3.6 Does the Case Narrative contain the "verbatim" statement (page B-12, section 2.5.1 of the SOM)?

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

ACTION: If "No", to any question in this section, contact the TOPO to obtain necessary resubmittals. If unavailable, document under the Contract Problems/ Non-Compliance section of the Data Assessment.

4.0 Data Validation Checklist

4.1 Check the package for the following (see SOM reporting requirements, section 2.1, page B-10):

- a. Is the package paginated in ascending order starting from the SDG narrative?
- b. Are all forms and copies legible?
- c. Assembled in the order set forth in the SOW?
- d. All Aroclor Data present?

PART A: Low/Medium Aroclor Analyses

1.0 Sample Conditions/Problems

1.1 Do the Traffic Reports/Chain-of-Custody Records, Sampling Trip Report or Lab Narrative indicate any problems with sample receipt, condition of samples, analytical problems or special circumstances affecting the quality of the data?

ACTION: If samples were not iced or the ice was melted upon arrival at the laboratory and the temperature of the cooler was > 10° C, then flag all positive results with a "J" and all non-detects "UJ".

2.0 Holding Times

STANDARD OPERATING PROCEDURE

USEPA Region II
 Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
 SOP HW-37/Aroclor, Revision 1

YES NO N/A

- 2.1 Have any Aroclor technical holding times, determined from date of collection to date of analysis, been exceeded? ___ [] ___
- 2.2 Preservation: Aqueous and Non-aqueous samples must be cooled at 4°C ± 2°C.

ACTION: Qualify sample results according to the following table.

Holding Time Actions for Low/Medium Aroclor Analyses

Matrix	Preserved	Criteria	Action	
			Detected Associated Compounds	Non-Detected Associated Compounds
Aqueous	No	≤ 7 days (extraction) ≤ 40 days (analysis)	J*	UJ*
	No	> 7 days (extraction) > 40 days (analysis)	J	UJ
	Yes	≤ 7 days (extraction) ≤ 40 days (analysis)	No qualification	
	Yes	> 7 days (extraction) > 40 days (analysis)	J	UJ
	Yes/No	> 28 Days (extraction)	J	R
Non-aqueous	No	≤ 14 days (extraction) ≤ 40 days (analysis)	J*	UJ*
	No	> 14 days (extraction) > 40 days (analysis)	J	UJ
	Yes	≤ 14 days (extraction) ≤ 40 days (analysis)	No qualification	
	Yes	> 14 days (extraction) > 40 days (analysis)	J	UJ
	Yes/No	> 28 Days (extraction)	J	R

* Only if cooler temperature exceeds 10°C (see ACTION in Section 1.1 above).
 No action required if temperature ≤ 10°C.

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

3.0 Surrogate Recovery (Form II ARO-1, Form II ARO-2, Form VIII ARO)

3.1 Are the Aroclor Recovery Summary Forms present?

ACTION: Contact the TOPO to obtain an explanation/resubmittal from the lab. If missing deliverables are unavailable, document the effect in the Data Assessment.

3.2 Were the two surrogates, tetrachloro-m-xylene (TCX) and decachlorobiphenyl (DCB) added to all samples, MS/MSD, LCS, blanks including standards?

ACTION: If no, use professional judgment in qualifying data as missing surrogate analyte may not directly apply to target analytes.

3.3 Were outliers marked with an asterisk on Form II?

ACTION: Circle all outliers with a red pencil.

If yes, were effected samples re-analyzed?

3.4 The RTs of the surrogates in each mid-point Aroclor standards used for continuing calibration verification, all samples, including MS/MSD, LCS and all blanks must be within the calculated RT window. TCX must be within ± 0.05 minutes and DCB must be within ± 0.10 minutes of the mean retention time (RT) determined from the initial calibration and tabulated in Form VIII Pest.

Were any outliers marked with an asterisk on Form VIII ARO?

ACTION: Circle all outliers with a red pencil. If any Surrogate is outside the required limits, qualify their associated target compounds (See Table below) as follows:

Surrogate Compound Recovery Action for Aroclors

Criteria	Action	
	Detected Target Compounds	Non-Detected Target Compounds
%R > 200%	J	No qualification
150% < %R ≤ 200%	J	No qualification
30% ≤ %R ≤ 150%	No qualification	
10% ≤ %R < 30%	J	UJ

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

%R < 10% (sample dilution not a factor)	J	R
%R < 10% (sample dilution is a factor)	J	Use Professional Judgement
RT out of RT window	Use professional judgment	
RT within RT window	No qualification	

Note: Blank analysis having surrogates out of specification:

The reviewer must give special consideration to the validity of associated samples. Basic concern is whether the blank problems represent an isolated problem with the blank alone or whether there is a fundamental problem with the analytical process. For example, if one or more samples in the batch show acceptable surrogate recoveries, the reviewer may choose to consider the blank problem to be an isolated occurrence.

ACTION: Note in the Data Assessment under Contract Problems/ Non-Compliance if the Lab did not perform reanalysis and reviewer's judgment regarding blank problem.

3.5 Are there any transcription/calculation errors between raw data and Form IIs? ___ [] ___

ACTION: If large errors exist, ask the TOPO to obtain an explanation/resubmittal from the lab, make any necessary corrections and note errors in the data assessment.

Note: Surrogate recovery limits criteria and qualification apply to samples diluted 5X and less. For samples diluted greater than 5X, recovery criteria does not apply Because it is assumed surrogate is diluted below the quantitation range.

4.0 Matrix Spike/Matrix Spike Duplicate Recovery (Form III)

Note: Data for MS/MSD will not be present unless requested.

4.1 Are the MS/MSD Recovery Forms (Form III ARO) present? [] ___ ___

4.2 Was the MS/MSD analyzed at the required frequency (once per SDG, or every 20 samples, whichever is more frequent)? [] ___ ___

ACTION: If any MS/MSD data are missing, take action as specified in section 3.1 above.

ACTION: No action is taken on MS/MSD data alone. However, using professional judgement, the validator may use the MS and MSD results in conjunction with other QC criteria and determine the need for some qualification of the data. If Any MS/MSD % recovery or RPD is out of specification, qualify data to include the consideration of the existence of interference in the raw

STANDARD OPERATING PROCEDURE

USEPA Region II
 Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
 SOP HW-37/Aroclor, Revision 1

YES NO N/A

data. Consideration include, but not limited to the following "Action":

Matrix Spike/Matrix Spike Duplicate Action for Aroclor

Criteria	Action	
	Detected Spike Compounds	Non-detected Spike Compounds
%R or RPD > Upper Acceptance Limit	J	No qualification
20% ≤ %R < Lower Acceptance Limit	J	UJ
%R < 20%	Use professional judgment	
Lower Acceptance Limit ≤ %R; RPD ≤ Upper Acceptance Limit	No qualification	

Note: If it can be determined that the results of the MS/MSD affects only the sample spiked, limit qualification to only this sample. However, use professional judgment when it is determined through the MS/MSD results that the laboratory is having systematic problem in the analysis of one or more analytes that affect all associated samples.

5.0 Blanks (Form IV)

5.1 Is the Aroclor Method Blank Summary (Form IV ARO) present for aqueous and soil samples? [] ___ ___

5.2 Frequency of Analysis: For the analysis of AROCLOR, has a method blank been analyzed for each SDG or every 20 samples, whichever is more frequent? [] ___ ___

ACTION: If any blank data are missing, take action as specified above in section 3.1. If blank data is not available, reject "R" all associated positive data. However, using professional judgement, the data reviewer may substitute field blank data for missing method blank data.

5.3 A separate Form IV should be present if part of an extraction batch required sulfur removal. In such cases some samples will be listed on two blank summary forms - once under the method blank, and once under the sulfur clean-up blank (PCBLK). Was this additional blank raw data and Form IV submitted when required? [] ___ ___

ACTION: If Form IV sulfur clean-up blank is missing, take action as specified in section 3.1 above.

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

	YES	NO	N/A
5.4 Has a Aroclor instrument blank been analyzed at the beginning of every 12 hr. period following the initial calibration sequence (minimum contract requirement)?	<input type="checkbox"/>	___	___
ACTION: If any blank data are missing, take action specified in Section 3.1.			
5.5 Was the correct identification scheme used for all Aroclor blanks? (See page B-39, section 3.3.7.3 of SOM01.1 for further information)	<input type="checkbox"/>	___	___
ACTION: Contact the TOPO to obtain resubmittals or make the required corrections on the forms. Document in the Data Assessment under Contract Problems/Non-Compliance all corrections made by the validator.			
5.6 <u>Chromatography</u> : Review the blank raw data chromatogram, quant. Reports and data system printout. Is the chromatographic performance (baseline stability) acceptable for each instrument?	<input type="checkbox"/>	___	___
ACTION: Use professional judgement to determine the effect on the data.			
5.7 Are all detected hits for target compounds in method, and field blanks less than the CRQL?	<input type="checkbox"/>	___	___
ACTION: IF no, an explanation and laboratory's corrective actions must be addressed in the case SDG narrative. Contact TOPO to request from Lab. revised narrative and make a note in the Contract Problems/Non-Compliance section of the Data Assessment.			

6.0 Contamination

NOTE: "Water blanks", "drill blanks", and distilled water blanks" are validated like any other sample, and are not used to qualify data. Do not confuse them with the other QC blanks discussed below.

6.1 Do any method/reagent or cleanup blanks contain positive hits for target Aroclor compounds with values greater than the CRQL for that analyte?	___	<input type="checkbox"/>	___
--	-----	--------------------------	-----

Note: The concentration of each target compound in the instrument blank must be less than the CRQL for that analyte.

ACTION: Make note in data assessment under Contract Problems/Non-Compliance if any blank contains hit above the CRQLs.

6.2 Do any instrument blanks contain positive Aroclor results with values greater than CRQLs?	___	<input type="checkbox"/>	___
---	-----	--------------------------	-----

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

ACTION: Take the action specified in section 6.1.

6.3 Do any field/rinse blanks have positive Aroclor results? ___ ___

NOTE: All field blank results associated with a particular group of samples (may exceed one per case) must be used to qualify data. Blanks may not be qualified because of contamination in another blank. Field blanks must be qualified for system monitoring compound, instrument performance criteria, spectral or calibration QC problems.

ACTION: Follow the directions in the table below to qualify results due to contamination. Use the largest value from all the associated blanks. If any blanks are grossly contaminated, all associated sample data should be qualified unusable (R).

Blank Action for Aroclor Analyses

Blank Type	Blank Result	Sample Result	Action for Samples
Method, Field, Sulfur Cleanup, Instrument	Detects	Not detected	No qualification required
	< CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification required
	= CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL	No qualification required
	> CRQL	< CRQL	Report CRQL value with a U
		≥ CRQL and < blank contamination	Report concentration of sample with a U
		≥ CRQL and ≥ blank contamination	No qualification required
	Gross contamination	Detects	Qualify results as unusable R

NOTE: Analytes qualified "U" for blank contamination are treated as "hits" when qualifying for calibration criteria.

Note: When applied as described in the table above, the contaminant concentration in the blank are multiplied by the sample dilution factor.

6.4 Are there field/rinse/equipment blanks associated with every sample? ___ ___

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

ACTION: Note in data assessment if there's no associated field/rinse/equipment blank.

Exception: samples taken from a drinking water tap do not have associated field blanks.

7.0 Aroclor Initial and Continuing Calibration

7.1 Are the following Forms, chromatograms and data system printouts present?

- a.) Form VI ARO-1/Aroclor Initial Calibration (Multipoint) ___ ___
- b.) Form VI ARO-2/Aroclor Initial Calibration (Multipoint) ___ ___
- c.) Form VI ARO-3/Aroclor Initial Calibration(Singlepoint) ___ ___
- d.) Form VII ARO/Aroclor Calibration Verification ___ ___
- e.) Form VIII ARO/Aroclor Analytical Sequence ___ ___
- f.) Form X ARO/Identification Summary for Multicomponent Analysis ___ ___

7.2 **Initial Calibration**

7.2.1 Was the following contract required initial calibration sequence provided by the laboratory? ___ ___

Initial Calibration Sequence	
1.	Aroclor 1221 CS3 (400ng/ml)
2.	Aroclor 1232 CS3 (400 ng/ml)
3.	Aroclor 1242 CS3 (400 ng/ml)
4.	Aroclor 1248 CS3 (400 ng/ml)
5.	Aroclor 1254 CS3 (400 ng/ml)
6.	Aroclor 1262 CS3 (400 ng/ml)
7.	Aroclor 1268 CS3 (400 ng/ml)
8.	Aroclor1016/1260 (100 ng/ml) CS1
9.	Aroclor1016/1260 (200 ng/ml) CS1
10.	Aroclor1016/1260 (400 ng/ml) CS1
11.	Aroclor1016/1260 (800 ng/ml) CS1

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

12.	Aroclor1016/1260 (1600 ng/ml) CS1
13.	Instrument Blank

ACTION: If initial calibration is not performed or not performed in the proper sequence, notify the TOPO and make a note in the data assessment.

7.3 Are there any transcription/calculation errors between raw data and the Forms? ___ [] ___

ACTION: If large errors exist, take action specified in section 3.1 above.

7.4 Mean Retention Time (RT) and RT Window

Were the following mean RT and RT window met: [] ___ ___

a.) The mean RT of each of the three to five major peaks were determined from the five-point initial calibration for all Aroclors

b.) RT window was calculated as ± 0.07 for each of the three to five major peaks and ± 0.05 and ± 0.10 for the surrogates tetrachloro-m-xylene and decachlorobiphenyl, respectively.

ACTION: If no, follow the action as specified in section 3.1.

7.5 Was at least one chromatogram from each of the Aroclor standards yield peaks that give deflection between 50-100% of full scale? [] ___ ___

ACTION: IF no, take action as specified in section 3.1.

7.6 Was the mean Calibration Factor (CF) calculated for the three to five major peaks of each Aroclor, as well as for the surrogates, over the initial calibration range? [] ___ ___

7.7 Were the Percent Relative Standard Deviation (%RSD) of the Calibration Factor for the three to five major peaks < 20% of each of the Aroclor compounds and surrogates? [] ___ ___

ACTION: If no, take action as specified in the following Table.

Initial Calibration Action for Aroclor Analyses

	Action
--	--------

Criteria

STANDARD OPERATING PROCEDURE

 Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
 SOP HW-37/Aroclor, Revision 1

YES NO N/A

	Detected Associated Compounds	Non-Detected Associated Compounds
Initial calibration is not performed or not performed in proper sequence	Use Professional Judgment and notify Contract Lab Program (CLP) Project Officer	
%RSD exceeds allowable limits *	J	UJ
%RSD within allowable limits *	No qualification	

* %RSD < 20.0% for Aroclors and surrogates (tetrachloro-m-xylene and decachlorobiphenyl).

7.8 Continuing Calibration Verification (CCV) (Form VII)

Were the Absolute Retention Time (RT) for each Aroclor and surrogate in the mid-point concentration (CS3) of the Standard used for CCV must be within the RT window determined from the initial calibration?

7.9 For opening CCV, or closing CCV that is used as an opening CCV for the next 12-hour period, the Percent Difference (%D) between the CF of each of the three to five peaks used to identify an Aroclor and surrogates in the mid-point concentration (CS3) of the Aroclor standards and the CF from the initial calibration must be within $\pm 15.0\%$.

7.10 For a closing CCV, the %D between the CF of each of the three to five peaks used to identify an Aroclor and surrogates in the mid-point concentration (CS3) of the Aroclor standards and the CF from the initial calibration must be within $\pm 50.0\%$.

7.11 No more than 14 hours may elapse from the injection of the instrument Blank that begins an analytical sequence (opening CCV) and the injection of the last mid-point concentration (CS3) of the Aroclor standards that ends an analytical sequence (closing CCV).

7.12 No more than 12 hours may elapse from the injection of the instrument blank that begins an analytical sequence (opening CCV) and the injection of the last sample or blank that is part of the same analytical sequence.

Were sections 7.8 to 7.12 met? [] — —

ACTION: If no, use the following table to qualify Aroclor data:

RT out of RT Window	Use professional Judgment *	
Percent Difference not within limits \pm 15% as specified in section 7.9 above	J	UJ
Percent Difference not within limits \pm 50% as specified in section 7.10 above	J	UJ
Time elapsed is greater than acceptable limits as specified in section 7.11 & 7.12 above	R	
Percent Difference, time elapsed and RT are within acceptable limits	No qualification	

* For non-detected target compounds in the affected samples, check to see if the sample chromatogram contain any peak that are close to the expected RT window of the Aroclor of interest.

If no peaks are present, consider the non-detected values to be valid and no qualification of the data is necessary.

If any peaks are present close to the expected RT window of the Aroclor of interest, qualify the non-detected values as presumptively present "N".

For detected compounds in the affected samples, if the peaks are within the RT window, no qualification of the data is necessary. If the peaks are close to the expected RT window of the Aroclors of interest, the reviewer may take additional effort to determine if sample peaks represent the compound of interest.

For example, the reviewer can examine the data package for the presence of three or more standards containing the Aroclor of interest that were run within the analytical sequence during which the sample was analyzed. If three or more such standards are present, the RT window can be re-evaluated using the mean RT of the standards.

If the peaks in the affected sample fall within the revised window, qualify the detected Aroclor as "JN".

If the reviewer cannot do anything with the data to resolve the problem of concern, qualify all non-detects as unuseable "R".

8.0 Analytical Sequence Check (Form VIII-ARO)

STANDARD OPERATING PROCEDURE

USEPA Region II
 Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
 SOP HW-37/Aroclor, Revision 1

		YES	NO	N/A
8.1	Is Form VIII-Pest present and complete for each column and each period of analyses?	[]	___	___
ACTION: If no, take action as specified in section 3.1				
8.2	Was the proper analytical sequence followed for each initial calibration and subsequent analyses, and all standards analyzed at the required frequency for each GC/ECD instrument used?	[]	___	___
ACTION: If no, use professional judgment to determine the severity of the effect on the data and qualify accordingly. Generally, the effect is negligible unless the sequence was grossly altered and/or the calibration was out of QC limits.				
8.3	Are the surrogate retention time (RT) from the initial calibration for TCX and DCB provided on Form VIII-Pest?	[]	___	___
ACTION: If no, take action as specified in section 3.1				
8.4	Was the asterisk (*) applied to the RT of any blanks, samples, standards, MS/MSD, and LCS that did not meet the QC Limits of ± 0.05 minutes for TCX (tetrachloro-m-xylene) and ± 0.10 minutes for DCB (decachlorobiphenyl)?	[]	___	___
ACTION: If any data are missing, take action specified in 3.1 above.				
If no, use professional judgment to determine the severity of the effect on the data and qualify accordingly. Document in the data assessment under Contract Problems/Non-Compliance.				

9.0 Sulfuric Acid and Gel Permeation Chromatography (GPC) Cleanup Procedures

9.1	Was sulfuric acid added to all extracts?	[]	___	___
-----	--	-----	-----	-----

Note: Sulfuric acid cleanup is mandatory for all extracts

ACTION: If no, take action specified in section 3.1

9.2 Gel Permeation Chromatography (GPC)

GPC is an optional cleanup procedure for both aqueous and non-aqueous samples that contain high molecular weight compounds that interfere with Aroclor analysis.

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

- 9.3 If GPC cleanup was performed on samples, GPC calibration is acceptable if the two UV traces meet the following requirements.
- a. Peaks must be observed and should be symmetrical for all compounds in the calibration solution.
 - b. Corn oil and phthalate peaks should exhibit greater than 85% resolution.
 - c. The phthalate and Methoxychlor peaks should exhibit greater than 85% resolution.
 - d. Methoxychlor and perylene peaks should exhibit greater than 85% resolution.
 - e. Perylene and sulfur peaks must be saturated and should exhibit greater than 90% baseline resolution.
 - f. The RT shift is less than 5% between UV traces for bis(2-ethylhexylphthalate and perylene.

9.4 Were all above criteria met?

[] — —

ACTION: If no, examine the raw data for the presence of high molecular weight contaminants. Examine the subsequent sample data for unusual peaks and use professional judgment in qualifying the data.

10.0 Laboratory Control Samples (LCSs)

10.1 LCSs provide information on the accuracy of the analytical method and laboratory performance.

Aroclor Laboratory Control Sample Recovery - Aqueous and Non-Aqueous

Compound	% Recovery QC Limits
Aroclor 1016	50 - 150
Aroclor 1260	50 - 150
Tetrachloro-m-xylene (surrogate)	30 - 150
Decachlorobiphenyl (surrogate)	30 - 150

10.2 Were the above recoveries met?

[] — —

ACTION: If no, qualify the sample data as follows:

STANDARD OPERATING PROCEDURE

USEPA Region II
 Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
 SOP HW-37/Aroclor, Revision 1

YES NO N/A

Criteria	ACTION	
	Detected Associated Compound	Non-Detected Associated Compound
%R> Upper Acceptance Limit	J	No qualification
%R< Lower Acceptance Limit	J	R
Lower Acceptance Limit < %R < Upper Acceptance Limit	No qualification	

11.0 Aroclor Identification (Form X ARO/Identification Summary for Multicomponent Analysis)

11.1 Is Form X (ARO) complete for every sample in which Aroclor was detected? [] ___ ___

ACTION: Take action as specified in section 3.1 above.

11.2 The identification of a Multi component Aroclor by GC method is based primarily on RT data and pattern recognition. Were the following requirements met: [] ___ ___

- a.) A Minimum of 3 major peaks were selected for each Aroclor. If more than one Aroclor is observed in a sample, a peak common to other Aroclor(s) must not be used to quantitate other Aroclor. Lab must choose different peaks to quantitate each Aroclor.
- b.) If a chromatogram is replotted electronically to meet these requirements, the scaling factor used must be displayed on the chromatogram, and both the initial chromatogram and the replotted chromatogram must be submitted in the data package.
- c.) The Retention Time (RT) of both of the surrogates and reported target compounds must be within the calculated RT window of both columns.

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

- d.) When no analytes are identified in the sample, the chromatograms of the sample extract must use the same scaling factor used for the low-point standard of the initial calibration associated with those samples.
- e.) Chromatogram must display the largest peak of any Aroclor detected in the sample at less than full scale.
- f.) If an extract must be diluted, chromatograms must display Aroclor peaks between 25-100% of full scale.

ACTION: If retention times (RT) or peak apex cannot be verified, contact TOPO to obtain rescaled chromatograms from the lab.

If data reviewer identifies a peak in both GC columns that fall within the appropriate RT windows, but was reported as non-detect, the compound may be false negative. If necessary, contact TOPO to instruct laboratory to re-evaluate the chromatograms.

11.3 Are there any transcription/calculation errors in Form I and Form X ARO?

ACTION: Take action as specified in section 3.1 above.

11.4 Are the RTs of Aroclor peaks within the established RT window for analyses on both columns?

11.5 Was the GC/MS confirmation provided for Aroclor concentration > 10 ug/ml in final extract?

NOTE: Laboratory is required to contact SMO to determine if GC/MS confirmation is required. Check the semivolatile TIC data for presence of Aroclors.

11.6 Is the per cent difference (%D) calculated for positive results on both columns < 25%?

Action: Reviewer must check columns for peak interferences for the positive hits. Qualify the Arclor (s) according to the following Table:

STANDARD OPERATING PROCEDURE

USEPA Region II
 Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
 SOP HW-37/Aroclor, Revision 1

YES NO N/A

Action on Qualifying Positive Aroclor Results

Percent Differences	Qualifier
0 - 25%	None
26 - 50%	"J"
51 - 100%	"JN"
> 50% (Aroclor value < CRQL)*	"U"
> 100%	"R"

* When the Aroclor value is below CRQL and %D > 50%, raise the value to CRQL and qualify "U", undetected.

NOTE: Professional judgement must be utilized when identifying PCBs, especially when samples are highly contaminated, and possess a significant amount of matrix interference.

12.0 Target Aroclor List (TCL)

12.1 Are the Aroclor Analysis Data Sheets (Form I ARO) present with required header information on each page for samples, MS/MSD (if required), method and instrument blanks (per column & analysis)?

[] ___ ___

12.2 Is the chromatographic performance acceptable with respect to baseline stability, full-scale attenuation, peak shape/resolution?

[] ___ ___

ACTION: If no, take action specified in section 3.1 above.

13.0 Compound Quantitation and Reported Detection Limits

13.1 Are there any transcription/calculation errors in the Form I results? Check at least two positive results. Were any errors found?

[] ___ ___

ACTION: If errors were found, take action as specified in section 3.1 above.

13.2 Are the contract required quantitation limits (CRQL) adjusted to reflect sample dilution?

[] ___ ___

STANDARD OPERATING PROCEDURE

USEPA Region II
Method: CLP/SOW, SOM01.2/Aroclor

Date: August 2007
SOP HW-37/Aroclor, Revision 1

YES NO N/A

ACTION: If errors exist, take action as specified in section 3.1 above.

ACTION: When a sample is required to be diluted, the lowest CRQL is used (unless a QC exceedance dictates the use of the higher CRQL from the diluted sample). Replace concentration which exceed the calibration range in the original analysis by crossing out the "E" value on the original Form I and substituting it with the result from the diluted sample. Specify which Form I to use. Use a red pencil and draw a red "X" across the entire page of all Form I's that should not be used, including those in the data summary package.

At the top or bottom of the Forms, write with red pencil, "DO Not Use".

Note: If the sample dilution factor (DF) is greater than 10, an additional 10 times more concentrated than the diluted sample extract must be analyzed and reported with the sample data. If the DF is less or equal to 10, but greater than 1, the results of the original undiluted analysis must also be reported (see SOM01.1/section 10.3.3.4/page D-44/ARO).

ACTION: IF the above requirement was not met, contact the TOPO to obtain an explanation/resubmittal from the lab and make a note in the Data Assessment under Contract Problems/Non-Compliance section.

13.3 For non-aqueous samples, were the percent moisture < 70%?

Action: If the % moisture ≥ 70.0% and < 90.0%, qualify detects as "J" and non-detects as approximated "UJ" If the % Moisture ≥ 90%, qualify detects as "J" and non-detects as "R"

14.0 Field Duplicates

14.1 Were any field duplicates submitted for Aroclor analysis?

ACTION: Compare the reported results for field duplicates and calculate the relative percent difference.

ACTION: Any gross variation between duplicate results must be addressed in the reviewer narrative. If large differences exist,

STANDARD OPERATING PROCEDURE

USEPA Region II

Date: August 2007

Method: CLP/SOW, SOM01.2/Aroclor

SOP HW-37/Aroclor, Revision 1

YES NO N/A

contact the TOPO to confirm identification
of field duplicates with the sampler.

Data Completeness and Deliverables			
Are the Field Chain of Custody Forms present for all samples?	_____	_____	_____
Is the Narrative or Cover Letter present?	_____	_____	_____
Do the Field Chain of Custody Reports or Lab Case Narrative indicate problems with sample receipt, sample condition, analytical procedures, or other comments regarding the quality of the data?	_____	_____	_____

ACTION: Use professional judgment to evaluate the effect of the noted problems on the quality of the data.

Reporting Requirements and Deliverables

Are the following forms present?			
Sample Data Summary (Form I)?	_____	_____	_____
Pesticide Spiked Sample Summary?	_____	_____	_____
Pesticide Duplicate Sample Summary?	_____	_____	_____
Pesticide Method Blank Summary?	_____	_____	_____
Pesticide Relative Retention Times?	_____	_____	_____
Pesticide Analytical Sequence Summary?	_____	_____	_____
Initial Calibration Summary?	_____	_____	_____
Continuing Calibration Summaries?	_____	_____	_____

Y N N/A

GC/MS Displays

Standard and sample SIM chromatograms. Do SIM and TIC chromatograms list date and time of analysis; the file name; sample number; and instrument I.D. number? _____

Percent peak resolution valley? _____

Pesticide window defining mix raw data? _____

Do SIM mass chromatograms display quantitation ion and confirmation ions? _____

Are the integrated area and peak height listed for all peaks 2.5 times above background? _____

Do all peaks show retention time at the maximum height? _____

Laboratory Records

Are the GC/MS Standard and Sample Run Log in chronological order? _____

Sample Extraction Log? _____

ACTION: If deliverables are missing, call the lab for explanation/resubmittal. If the lab cannot provide missing deliverables, assess the effect on the validity of the data. Note in the reviewers narrative.

Holding Times

Were the following holding times met:

Aqueous samples were extracted within 7 days of sample collection? _____

Solid samples were extracted within 7 days of sample collection? _____

All samples were analyzed within 40 days of extraction? _____

ACTION: If holding times are exceeded, flag all data as estimated "J".

If holding times from collection to extraction, or from extraction to analysis have been grossly exceeded, use professional judgment to determine whether non-detects shall be rejected.

Y N N/A

Preservation Requirements

Is the cooler temperature $\leq 10^{\circ}\text{C}$ for aqueous and solid samples from the time of collection until receipt at the laboratory?

ACTION: If cooler temperature $>10^{\circ}\text{C}$, flag non-detects as "UJ" and detects as "J".

Column Performance

Does the absolute retention time of Methoxychlor exceed 39 minutes on a DB-17 column?

ACTION: If column performance criteria was not met, a detailed discussion of the problems observed and potential effects on analytical data obtained should be included in the data assessment narrative.

Endrin/4,4'-DDT Breakdown

This test is run after calibration or calibration verification to assure the labeled pesticides do not decompose in the GC.

Measure and sum the peak areas for both the exact m/z's separately for 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, endrin, endrin aldehyde, and endrin ketone.

Add the summed peak areas for endrin aldehyde and endrin ketone and separately add the peak areas for 4,4'-DDD and 4,4'-DDE.

Calculate the endrin and 4,4'-DDT breakdown as follows:

$$\text{Endrin breakdown (percent)} = \frac{(\text{areas for endrin aldehyde} + \text{endrin ketone})}{\text{areas for endrin}} \times 100$$

$$4,4\text{'-DDT breakdown (percent)} = \frac{(\text{areas for } 4,4\text{'-DDD} + 4,4\text{'-DDE})}{\text{areas for } 4,4\text{'-DDT}} \times 100$$

Has the individual % breakdown exceeded 20.0% for:

endrin?

4,4'-DDT?

Y N N/A

ACTION: If any % breakdown has failed the QC criteria in the breakdown check standard, qualify all sample analyses in the entire analytical sequence as described below.

- a. If 4,4'-DDT breakdown is greater than 20%:
 - i. Qualify all positive results for DDT with "J". If DDT was not detected, but DDD and DDE are positive, then qualify the quantitation limit for DDT as unusable ("R").

- b. If endrin breakdown is greater than 20.0%:
 - i. Qualify all positive results for DDT with "J". If endrin was not detected, but endrin aldehyde and endrin ketone are positive, then qualify the quantitation limit for endrin as unusable ("R").

Instrument Performance

Mass Calibration - Mass calibration of the MS must be performed prior to analyzing calibration solutions, blanks, samples, and QC samples. A static resolving power of at least 8,000 (10% valley definition) must be demonstrated at appropriate masses before and at the end of each shift prior to any analysis is performed at appropriate masses. If the analyses are performed on successive shifts, only the beginning of the shift static resolving power is required. Include in the narrative, minimum required resolving power of 8,000 was obtained for perfluorokerosene (PFK) ion 304.9824. This is done by first measuring peak width at 5% of the maximum. Resolving power, then is calculated using the formula,

$$\text{Resolving Power} = m/\Delta m$$

Was mass calibration performed at the frequency given above? _____

Initial 5-Point Calibration

The initial calibration standard solutions (CS1-CS5, Table 4*) must be analyzed prior to any sample analysis. However, initial calibration should be analyzed whenever the labeled compounds response in the sample does not meet all criteria. The calibration standards must be analyzed on the same instrument using the same GC/MS conditions that were used to perform the mass calibration.

*NOTE: All tables mentioned throughout this checklist are taken from USEPA, Method 1699, 2007

	Y	N	N/A
The following MS/DS conditions must be used:			
Is mass calibration performed as described earlier?	_____	_____	_____
Is the total scanning time \leq 1 second?	_____	_____	_____
Were SIM data acquired for each of the ions listed in Table 6?	_____	_____	_____
Do the two SIM ions for each pesticide maximize simultaneously and within 3 seconds of the corresponding labeled isomer ions?	_____	_____	_____
Do the relative ion abundances for target analyte pesticides meet criteria listed in Table 6?	_____	_____	_____
In all calibration solutions, is the signal to noise ratio (S/N) for the GC signal present in every SICP, including the ones for the labeled standards \geq 10?	_____	_____	_____
Does the percent relative standard deviation (%RSD) for the mean response factor (RRF) from the initial calibration for unlabeled standards exceed \pm 20%?	_____	_____	_____

ACTION:

- 1) If the %RSD for any isomer exceeds 20%, flag the associated sample positive results for that specific isomer as estimated ("J"). No effect on the non-detect data.
- 2) If the ion abundance ratio for an analyte is outside the limits flag the results for that analyte R (reject).
- 3) If the ion abundance ratio for an internal standard or labeled analog compound falls outside the QC limits flag the associated positive hits with J. No effect on the non-detects.
- 4) If the signal to noise ratio (S/N) is below control limits, use professional judgment to determine quality of the data.
- 5) If the selected monitoring ions specified in Table 7 were not used for data acquisition, the lab must be asked for an explanation. If an incorrect ion was used, reject all the associated data.
- 6) If mass calibration criteria as specified earlier is not met, specify that in narrative notes.
- 7) Non-compliance of all other criteria specified above should be evaluated using professional judgement.

Spot-check response factor calculations and ion ratios. Ensure that the correct quantitation ions for the unlabeled pesticides and labeled compounds were used. In addition verify that the appropriate labeled compound was used for each isomer.

Y N N/A

Formulas

Target Analytes Quantitated by Isotopic Dilution

The response of each native organochlorine pesticide relative to its labeled analog is determined using the area responses of both the primary and secondary exact m/z's specified in Table 2, for each calibration standard, as follows:

$$RR = \frac{(A1_n + A2_n) C_l}{(A1_l + A2_l) C_n}$$

Where:

$A1_n$ and $A2_n$ = The areas of the primary and secondary m/z's for the organochlorine pesticide.

$A1_l$ and $A2_l$ = The areas of the primary and secondary m/z's for the labeled compound.

C_l = The concentration of the labeled compound in the calibration standard (Table 4).

C_n = The concentration of the native compound in the calibration standard (Table 4).

Target Analytes Quantitated by Internal Standard Method

Response factors – Calibration requires the determination of response factors (RF) defined by the following equation:

$$RF = \frac{(A1_s + A2_s) C_{is}}{(A1_{is} + A2_{is}) C_s}$$

Where:

$A1_s$ and $A2_s$ = The areas of the primary and secondary m/z's for the organochlorine pesticide.

$A1_{is}$ and $A2_{is}$ = The areas of the primary and secondary m/z's for the internal standard.

C_{is} = The concentration of the internal standard (Table 4).

C_s = The concentration of the compound in the calibration standard (Table 4).

Y N N/A

Continuing Calibration (CS-4 VER)

The continuing calibration must be performed at the beginning of a 12 hour period after successful mass resolution and GC resolution performance checks.

Was the continuing calibration run at the required frequency? _____

Were the following MS/DS conditions were used:

A. Was the total scanning time ≤ 1 second? _____

B. Were SIM data acquired for each of the ions listed in Table 6? _____

The following GC criteria must be met:

C. The two SIM ions for each pesticide must maximize simultaneously (± 3 sec) and within 3 seconds of the corresponding ions of the labeled isomers. _____

D. For the CS-4 standard solution, the signal to noise ratio (S/N) for the unlabeled pesticide ions shall be > 10 . _____

E. For the labeled analog compounds and the internal standards, the signal to noise ratio (S/N) shall be > 10 . _____

F. The relative ion abundance criteria (Table 6) for all pesticides shall be met. _____

G. The relative ion abundance criteria for all labeled analog compounds and internal standards (Table 6) must be met. _____

H. The found concentration for each analyte must fall within the concentration range specified in Table 4. _____

I. The absolute retention times of the GCMS internal standards during the CS-4 (VER) test must be within ± 15 seconds of the RTs obtained during the initial calibration. _____

Y N N/A

J. Further, the RRT of native pesticides and labeled compounds in the verification test must be within 5% of the RRT given in Table 2. _____

ACTION: If any requirements listed in sections A, B, C, D, E, F, or G are not met, reject all data ("R" flag) specifically affected by the problem.

When the found concentration of the calibration verification sample falls outside the specified allowable range, all data for outlier congeners are flagged "J".

If the continuing calibration standard was not analyzed at the required frequency, reject all the data.

If any of the requirements listed in Section I are not met, use professional judgment to determine the validity of data.

Sample Data

The following MS/DS conditions were used:

Was the scanning time ≤ 1 second? _____

Were SIM data acquired for each of the ions listed in Table 2? _____

Identification Criteria

A. For the organochlorine pesticides found present, the relative retention time at the maximum peak height of the analyte must be within 5% of the RTs listed in Table 2. _____

B. All specified ions listed in Table 2 (analytical method) for each pesticide found present and the labeled standards must be present in the SICP. The two SIM ions for the analyte, the labeled analog compounds and internal standards must maximize simultaneously (± 2 seconds). _____

C. The integrated ion current for each characteristic ion of the analyte identified as positive must be at least 2.5 times background noise and must have not saturated the detector. _____

D. The integrated ion current for the labeled analog compound and internal standard characteristic ions must be at least 10 times background noise. _____

Y N N/A

E. The relative ion abundance criteria (Table 6) for all pesticides found present must be within $\pm 20\%$ of the ratio in the daily CS-4 VER test. _____

F. The relative ion abundance criteria for the labeled analog compounds and internal standards must be met (Table 6), or within $\pm 20\%$ of the ratio in the daily CS-4 VER test. _____

G. The analyte concentration must be within the calibration range. If not, dilution should have been made to bring the concentration within the calibration range. Was the above criteria met? _____

H. Do any lock mass ion signals show peak deflections of greater than 20% in the retention time areas of any analyte? _____

ACTION: Reject (flag "R") all positive data for the analytes which do not meet criteria listed in sections A & B.

If the criteria listed in section C are not met but all other criteria are met, qualify all positive data of the specific analyte with "J".

If the requirements listed in section D are not met but all other requirements are met qualify the positive data of the corresponding analytes with "J".

If the analytes reported positive do not meet ion abundance criteria, section E, reject "R" all positive data for these analytes.

If labeled analog compounds and internal standards do not meet ion abundance criteria (Table 6) but they meet all other criteria flag all corresponding data with "J".

If any peak deflection is greater than 20%, then qualify the associated compound with a "J".

Spot-check calculations for positive data and verify that the same labeled analog compounds used to calculate RRFs were used to calculate concentrations. _____

Y N N/A

To recalculate the concentration of organochlorine pesticides in the sample use the following equations:

Isotope dilution quantation -

$$M_{ex} \text{ (ng/mL)} = (A_{1_n} + A_{2_n}) \times M_{lb} / (A_{1_{lb}} + A_{2_{lb}}) \times RRF$$

Where:

M_{ex} = The mass of the organochlorine pesticide in the sample extract.

M_{lb} = The mass of the labeled compound in the sample extract.

A_{1_n} and A_{2_n} = Area of the primary and secondary ion for the native organochlorine pesticide.

$A_{1_{lb}} + A_{2_{lb}}$ = Area of the primary and secondary ion for the labeled compound.

Any peaks representing the other organochlorine pesticides are quantitated using an average of the response factors from all of the labeled organochlorine pesticides at the same level of chlorination.

Method Blanks

Has a method blank been extracted and analyzed with each batch of 20 samples, or less, per matrix?

Was the method blank analyzed immediately after analysis of the OPR to demonstrate freedom of concentration?

If pesticides are carried over from the OPR, analyze one or more aliquots of solvent between OPR and the method blank.

If samples of same matrix were analyzed in different events (i.e. different shifts or days) has one blank for each matrix been extracted and analyzed for each event?

ACTION: If the proper number of method blanks were not analyzed, notify the contractor. If the reviewer is unavailable, reject all positive sample data. However, the reviewer may also use professional judgement to accept or reject positive sample data if no blank was run.

Y	N	N/A
_____	_____	_____

Are any organochlorine pesticides found in the method blank at a concentration greater than the PQL?

ACTION: If the analyte has a reported concentration that is > 5 times the PQL, no qualification is necessary. All associated positive target analyte results \leq 5 times the PQL are flagged "J".

Rinsate Blank

Was a minimum of one rinsate blank collected for each batch of 20 samples, or one each day sampling equipment decontamination procedures are performed, whichever is more frequent?

_____	_____	_____
-------	-------	-------

Do any rinsate blanks show the presence of pesticides at amounts greater than the PQL?

_____	_____	_____
-------	-------	-------

ACTION: If the analyte has a reported concentration that is > 5 times the PQL, no qualification is necessary. All associated positive target analyte results \leq 5 times the PQL are flagged "J".

Labeled Analog Recoveries

Were the samples spiked with all the labeled analog compounds as specified in the method?

_____	_____	_____
-------	-------	-------

Were labeled analog compound recoveries within the required (25-150%) limits?

_____	_____	_____
-------	-------	-------

If not, were samples reanalyzed?

_____	_____	_____
-------	-------	-------

ACTION: If the labeled analog compound recovery was below 25%, reject "R" all associated non-detect data (EMPC/EDL) and flag with "J" all positive data. If the labeled analog compound recovery is above the upper limit (150%) flag all associated data (positive and non-detect data) with "J".

If the labeled analog compound recovery is less than 10% reject ("R" flag) all associated data.

Y N N/A

Recalculate the percent recovery for each labeled analog compound in the sample extract, (Ris), using the formula:

$$\% \text{ Rec }_1 = \frac{(A_{11} + A_{12})}{(A_{is1} + A_{is12})} \times Q_{is} \times 100$$

$A_{n1} + A_{n2}$ = integrated areas of the two quantitation ions of isomer of interest. (Target analyte).

$A_{11} + A_{12}$ = integrated areas of the two quantitation ions of the appropriate labeled analog compound.

$A_{is1} + A_{is2}$ = integrated areas of the two quantitation ions of the appropriate internal standard.

Q_n = quantity of the unlabeled pesticide analyte injected (pg)

Q_1 = quantity of the appropriate labeled analog compound injected (pg)

Q_{is} = quantity of the appropriate internal standard injected (pg)

Internal Standards

Are the internal standard areas for every sample and blank within the upper and lower limits of each associated CS-4 VER? _____

Area upper limit = +100% of recovery standard area.

Area lower limit = - 50% of recovery standard area.

Is the retention time of each internal standard within 10 seconds of the associated CS-4 VER? _____

ACTION: If the internal standard area is outside the upper or lower limits flag all related positive and non-detect data with "J" regardless whether the labeled analog compound recoveries met specifications or not.

If extremely low area counts (<25%) are reported flag all associated non-detect data as unusable "R" and the positive data "J".

If the retention time of the internal standard differs by more than 10 seconds from the CS-4 use professional judgment to determine the effect on the results. A time shift of more than 10 seconds may cause certain analytes to elute outside the retention time window.

Y N N/A

Matrix Spike/Matrix Spike Duplicate (Field Sample)

The following sample ID was chosen for MS/MSD analysis: _____

Was a matrix spike analyzed at the frequency of one per SDG, per matrix? _____

Was the percent recovery of all organochlorine pesticides within 50-150% and Toxaphene 20-180% for both aqueous and solid samples? _____

ACTION: If problems such as interferences are observed and if the recovery of the MS is out of the 50-150% acceptance range for either an aqueous or soil sample, qualify the result for the affected target analyte in the sample used for the MS/MSD as estimated "J".

Was the relative percent difference (RPD) between the matrix spike/matrix spike duplicate <25%? _____

ACTION: If the precision of the MS/MSD analyses is >50% RPD, qualify the value for that analyte in the sample used for the MS/MSD as estimated "J".

Field Duplicate Samples

Sample IDs of the field duplicate pair: _____

For every batch of 20 samples or less collected, was there a sample designated as duplicate? _____

NOTE: For Aqueous: $RPD \leq 20\%$ when target is detected in both field duplicate samples at $> 5x$ the PQL or concentrations differ by $< 2x$ the PQL when detects are $\leq 5x$ PQL for both field duplicate samples.

For Soil: $RPD \leq 50\%$ when target is detected in both field duplicate samples at $> 5x$ PQL, or concentration differs by $< 2x$ the PQL when detects are $\leq 5x$ PQL for both field duplicate samples.

ACTION: The duplicate results must be used in conjunction with other QC data. If no hits are reported, precision may be assessed from the internal standard recoveries.

Y N N/A

IPR

Was an initial precision and accuracy demonstration performed for the appropriate matrix per Section 9.2 of Method 1699, 2007?

Were the results of the IPR evaluation acceptable when compared to the acceptance limits for each analyte listed in Table 5?

ACTION: If IPR data was not provided by the laboratory, contact the lab to obtain the results of the IPR study.

If the results of the laboratories IPR study do not meet the acceptance criteria for performance tests listed in Table 5, contact the laboratory to initiate remediation of technical difficulties. Further sample analyses should not be performed until the laboratory satisfactorily demonstrates the IPR performance test.

OPR

Was an ongoing precision and recovery (OPR) standard prepared for each sample or sample set (to a maximum of 20 samples)?

Has the OPR been analyzed prior to analysis of the samples from the same batch?

Do the results of all OPR standard meet the acceptance criteria for all target analytes of 50-150% except Toxaphene which is 20-180% for both aqueous and soil?

ACTION: If the laboratory failed to process an OPR sample with the associated field samples, qualify all target analyte results as estimated "J".

ACTION: When the observed OPR recovery is less than 10%, associated non-detect results are flagged "R" rejected and positive results are flagged "J" estimated.

When the observed OPR recovery is lower than the lowest acceptance limit but greater than 10%, associated non-detect results are flagged "UJ" estimated non-detect and positive results are flagged "J" estimated.

When the observed OPR recovery is higher than the highest acceptance limit flag only associated positive results "J" estimated.

Compute the percent recovery of the organochlorine pesticides with labeled analogs by isotope dilution.

Compute the percent recovery of each labeled compound by the internal Standard method.

Data Validation Qualifiers

Qualifier	Description
J	Estimated value (bias undetermined) – The analyte was positively identified; but the associated numerical value is the approximate concentration of the analyte in the sample.
JH	Estimated value (potential high bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential high bias, of the analyte in the sample.
JL	Estimated value (potential low bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential low bias, of the analyte in the sample.
UJ	Estimated non-detect - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
UJL	Estimated non-detect (potential low bias) – The analyte was not detected and the report sample quantitation limit is biased low.
UJH	Estimated non-detect (potential high bias) – The analyte was not detected and the reported sample quantitation limit is biased high.
M	The analytical result reported was obtained from a sediment sample found to contain between 50 and 90 percent moisture and had no other data qualifiers added during the data validating process.
NJ	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.
NJH	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration with a potential high bias, of the analyte concentration.
EMPC	Estimated Maximum Possible Concentration (EMPC).
R	The sample results are rejected. Due to a significant QA/QC problem, the analysis is invalid and provides no information as to whether the analyte is present or not.

INTRODUCTION

Scope and Applicability

This SOP offers detailed guidance in evaluating laboratory data generated according to the USEPA SW-846, Method 8260B. The validation methods and actions discussed in this document are based on the requirements set forth in USEPA SW-846, Chapter Two, Rev 3, December 1996; Method 8000B, Rev 2, December 1996; Method 8260B, Rev 2, December 1996; and "USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review," February, 1994. This document covers technical as well as method specific problems; however situations may arise where data limitations must be assessed based on the reviewer's own professional judgement.

Summary

To ensure a thorough evaluation of each result in a data case, the reviewer must complete the checklist within this SOP, answering specific questions while performing the prescribed "ACTIONS" in each section. Qualifiers (or flags) are applied to questionable or unusable results as instructed. The data qualifiers discussed in this document are defined on page 25.

The reviewer must prepare a detailed data assessment to be submitted along with the complete SOP checklist. The Data Assessment must list all data qualifications, reasons for qualifications, instances of missing data, and contract non-compliance.

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S))Q
YES NO N/A

I. PACKAGE COMPLETENESS AND DELIVERABLES

CASE NUMBER: _____ LAB: _____

SITE NAME: _____

1.0 Data Completeness and Deliverables

1.1 Has all data been submitted in CLP deliverable format or CLP Forms Equivalent? [] _____

ACTION: If not, note the effect on review of the data in the Data Assessment narrative.

2.0 Cover Letter, SDG Narrative

2.1 Is a laboratory narrative, signed release, or cover letter present? [] _____

2.2 Are case number and SDG number(s) contained in the narrative or cover letter? [] _____

II. VOLATILE ANALYSES

1.0 Traffic Reports and Laboratory Narrative

1.1 Are the Traffic Reports, Chain of Custodies, or signed releases from the field samplers present for all samples? [] _____

ACTION: If no, contact the laboratory/sampling team for replacement of missing or illegible copies.

1.2 Is a sampling trip report present (if required)? [] _____

1.3 Sample Conditions/Problems

1.3.1 Do the Traffic Reports, Chain of Custodies, or Lab Narrative indicate any problems with sample receipt, condition of samples, analytical problems or special notations affecting the quality of the data? _____ [] _____

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S)) Q
YES NO N/A

- ACTION: If all the VOA vials for a sample have air bubbles or the VOA vial analyzed had air bubbles, flag all positive results "J" and all non-detects "R".
- ACTION: If any sample analyzed as a soil, other than TCLP, contains 50%-90% water, all data should be flagged as estimated ("J"). If a soil sample, other than TCLP, contains more than 90% water, flag all positive results "J" and all non-detects "R".
- ACTION: If samples were not iced or if the ice was melted upon receipt at the laboratory and the temperature of the cooler was elevated (>10°C), flag all positive results "J" and all non-detects "U".

2.0 Holding Times

2.1 Have any volatile holding times, determined from date of collection to date of analysis, been exceeded?

The holding time for aqueous samples is 14 days.
The holding time for soils is 10 days.

NOTE: If unpreserved, aqueous samples maintained at 4°C for aromatic hydrocarbons analysis must be analyzed within 7 days. If preserved with acid to a pH<2 and stored at 4°C, then aqueous samples must be analyzed within 14 days from time of collection. If uncertain about preservation, contact the laboratory/sampling team to determine whether or not samples were preserved.

- ACTION: If holding times are exceeded, flag all positive results as estimated ("J") and sample quantitation limits as estimated ("U"), and document in the narrative that holding times were exceeded.

If analyses were done more than 14 days beyond holding time, either on the first analysis or upon reanalysis, the reviewer must use professional judgement to determine the reliability of the data and the effects of additional storage on the sample results. At a minimum, all results should be qualified "J", but the reviewer may determine that

STANDARD OPERATING PROCEDURE

Date: June 1999
 SOP HW-24, Rev. 1

S))Q
 YES NO N/A

non-detect data are unusable ("R"). If holding times are exceeded by more than 28 days, all non-detect data are unusable (R).

3.0 Surrogate Recovery (CLP Form II Equivalent)

3.1 Have the volatile surrogate recoveries been listed on Surrogate Recovery forms for each of the following matrices:

- a. Water ___ ___
- b. Soil ___ ___

3.2 If so, are all the samples listed on the appropriate Surrogate Recovery forms for each matrix:

- a. Water ___ ___
- b. Soil ___ ___

ACTION: If large errors exist, deliverables are unavailable or information is missing, document the effect(s) in Data Assessments and contact the laboratory/project officer/appropriate official for an explanation/resubmittal, make any necessary corrections and document effect in the Data Assessment.

3.3 Were outliers marked correctly with an asterisk? ___ ___

ACTION: Circle all outliers with a red pencil.

3.4 Were one or more volatile surrogate recoveries out of specification for any sample or method blank (Surrogate recovery is 80-120% for aqueous and 70-130% for soil/sediment samples)? ___ ___

NOTE: Laboratory may use in-house performance criteria (as per SW-846, 8000B-43, Sect. 8.6 & 8.7).

- If yes, were samples reanalyzed? ___ ___
- Were method blanks reanalyzed? ___ ___

ACTION: If all surrogate recoveries are > 10% but 1 or more compounds do not meet method specifications:

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S))
YES NO N/A

- 1. Flag all positive results as estimated ("J").
- 2. Flag all non-detects as estimated detection limits ("U") when recoveries are less than the lower acceptance limit.
- 3. If recoveries are greater than the upper acceptance limit, do not qualify non-detects.

If any surrogate has a recovery of < 10%:

- 1. Positive results are qualified with ("J").
- 2. Non-detects for that should be qualified as unusable ("R").

NOTE: Professional judgement should be used to qualify data that have method blank surrogate recoveries out of specification in both original and reanalyses. Check the internal standard areas.

3.5 Are there any transcription/calculation errors between raw data and reported data?

ACTION: If large errors exist, take action as specified in section 3.2 above.

4.0 Laboratory Control Samples/Matrix Spikes (CLP Form III Equivalent)

4.1 Have the volatile Laboratory Control Samples (LCS) recoveries been listed on the laboratory reporting form?

NOTE: If the data has not been reported, then contact the laboratory/project officer to obtain the information necessary to evaluate the spike recoveries in the MS, MSD, and LCS. The required data which should have been provided by the lab include the analytes and concentrations used for spiking, background concentrations of the spiked analytes (i.e., concentrations in unspiked sample), methods and equations used to calculate the QC acceptance criteria for the spiked analytes, percent recovery data for all spiked analytes.

The data reviewer must verify that all reported equations and percent recoveries are correct before proceeding to the next section.

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S))Q
YES NO N/A

NOTE: The LCS spike is spiked with the same analytes at the same concentrations as the matrix spike (as per SW-846, 8000B-40, Sect. 8.5) if different, make note in Data Assessment.

4.2 Were Laboratory Control Samples analyzed at the required frequency for each of the following matrices:

- a. Water [] ___ ___
- b. Soil [] ___ ___
- c. Med Soil [] ___ ___

ACTION: If any LCS data are missing, take the action specified in section 3.2 above.

4.3 How many LCS volatile spike recoveries are outside QC limits?

Water Soil
 ___ out of ___ ___ out of ___

ACTION: Circle all outliers with a red pencil.

4.4 Were one or more of the volatile LCS recoveries outside of the in-house laboratory recovery criteria for spiked analytes? If none are present, then use 70-130% recovery as per SW-846, 8000B-41, Sect. 8.5.4.

___ [] ___

- ACTION:
1. If the recovery is > upper in-house limit (or 130%), only positive values for the affected compound(s) are flagged "J".
 2. If the recovery is < lower in-house limit (or 70%), flag positive values for the affected compound(s) "J" and non-detects "R".

All analytes in associated sample results are qualified for the following criteria.

1. If 25% of the LCS recoveries were < lower in-house limit (or 70%) qualify all positive results "J" and all non-detects "R".
2. If two or more LCS recoveries were < 10% qualify all positive results "J" and all non-detects "R".

STANDARD OPERATING PROCEDURE

SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S)) Q
YES NO N/A

- 4.5 Have the volatile Matrix Spike(MS)/Matrix Spike Duplicate (MSD) recoveries been listed on the laboratory reporting form?
- 4.6 Were matrix spikes analyzed at the required frequency for each of the following matrices:
 - a. Water
 - b. Soil
 - c. Med Soil

NOTE: The laboratory should use one matrix spike and a duplicate analysis of an unspiked field sample if target analytes are expected in the sample. If the sample is not expected to contain target analytes, a MS/MSD should be analyzed (SW-846, 8260B-25, Sect. 8.4.2)

ACTION: If any matrix spike data are missing, take the action specified in 3.2 above.

4.7 How many MS/MSD volatile spike recoveries are outside QC limits?

Water Soil
_____ out of _____ out of _____

4.8 How many RPD's for matrix spike and matrix spike duplicate recoveries are outside QC limits?

Water Soil
_____ out of _____ out of _____

ACTION: Circle all outliers with a red pencil.

4.9 Were one or more of the volatile MS/MSD recoveries outside of the in-house laboratory recovery criteria for spiked analytes? If none are present, then use 70-130% recovery as per SW-846, 8000B-41, Sect. 8.5.4. _____ _____

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S))
YES NO N/A

NOTE: If any individual % recovery in the MS (or MSD) falls outside the designated range for recovery the reviewer should determine if there is a matrix effect. A matrix effect is indicated if the LCS data are within limits but the MS data exceeds the limits.

NOTE: MS/MSD criteria apply only to the original sample, its dilutions, and the associated MS/MSD samples.

- 1. If the recovery is > upper in-house limit/130%, only positive values for the affected compound(s) are flagged "J".
- 2. If the recovery is < lower in-house limit/70%, flag positive values for the affected compound(s) "J" and non-detects "UJ".
- 3. If two or more MS/MSD recoveries were < 10% qualify all positive results "J" and all non-detects "R".

5.0 Blank (CLP Form IV Equivalent)

5.1 Is the Method Blank Summary form present? ___ ___

5.2 Frequency of Analysis:

Has a reagent/method blank analysis been reported for samples of similar matrix, or concentration level, and for each extraction batch? ___ ___

5.3 Has a method blank been analyzed for each GC/MS system used ? ___ ___

ACTION: If any method blank data are missing, take action as specified in section 3.2. If not available, use professional judgement to determine if the associated sample data should be qualified.

5.4 Chromatography: review the blank raw data - chromatograms (RICs), quant reports or data system printouts and spectra.

Is the chromatographic performance (baseline stability) for each instrument acceptable for the volatiles? ___ ___

ACTION: Use professional judgement to determine the effect on the data.

STANDARD OPERATING PROCEDURE

US EPA Region II

6.0 Contamination

NOTE: "Water blanks", "drill blanks" and "distilled water blanks" are validated like any other sample and are not used to qualify the data. Do not confuse them with the other QC blanks discussed below.

6.1 Do any method/instrument/reagent blanks have positive results for target analytes and/or TICs? When applied as described below, the contaminant concentration in these blanks are multiplied by the sample dilution factor and corrected for percent moisture where necessary. [] ___ ___

6.2 Do any trip/field/rinse/ blanks have positive results for target analytes and/or TICs? ___ [] ___

ACTION: Prepare a list of the samples associated with each of the contaminated blanks. (May attach a separate sheet.)

NOTE: All field blank results associated with a particular group of samples (may exceed one per case) must be used to qualify data. Blanks may not be qualified because of contamination in another blank. Field Blanks must be qualified for outlying surrogates, poor spectra, instrument performance or calibration QC problems.

ACTION: Follow the directions in the table below to qualify sample results due to contamination. Use the largest value from all the associated blanks.

STANDARD OPERATING PROCEDURE

7.0 GC/MS Apparatus and Materials

7.1 Did the lab use the proper gas chromatographic column(s) for analysis of volatiles by Method 8260B? Check raw data, instrument logs or contact the lab to determine what type of column(s) was (were) used.
For the analysis of volatiles, the method requires requires the use of 60 m. x 0.75 mm capillary column, coated with VOCOL(Supelco) or equivalent column. (see SW-846, page 8260B-7, section 4.9.2)

ACTION: If the specified column, or equivalent, was not used, document the effects in the Data Assessment. Use professional judgement to determine the acceptability of the data.

8.0 GC/MS Instrument Performance Check (CLP Form V Equivalent)

8.1 Are the GC/MS Instrument Performance Check forms present for Bromofluorobenzene (BFB), and do these forms list the associated samples with date/time analyzed?

8.2 Are the enhanced bar graph spectrum and mass/charge (m/z) listing for the BFB provided for each twelve hour shift?

8.3 Has an instrument performance check solution (BFB) been analyzed for every twelve hours of sample analysis per instrument?(see Table 4, SW-846, page 8260B-36)

ACTION: List date, time, instrument ID, and sample analyses for which no associated GC/MS tuning data are available.

DATE	TIME	INSTRUMENT	SAMPLE NUMBERS
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____

ACTION: If the laboratory/project officer/appropriate official cannot provide missing data, reject ("R") all data generated outside an acceptable twelve hour calibration interval.

YES NO N/A

ACTION: If mass assignment is in error, flag all associated sample data as unusable, "R".

8.4 Have the ion abundances been normalized to m/z 95?

8.5 Have the ion abundance criteria been met for each instrument used?

ACTION: List all data which do not meet ion abundance criteria (attach a separate sheet).

ACTION: If ion abundance criteria are not met, take action as specified in section 3.2.

8.6 Are there any transcription/calculation errors between mass lists and reported values? (Check at least two values but if errors are found, check more.)

8.7 Have the appropriate number of significant figures (two) been reported?

ACTION: If large errors exist, take action as specified in section 3.2.

8.8 Are the spectra of the mass calibration compound acceptable?

ACTION: Use professional judgement to determine whether associated data should be accepted, qualified, or rejected.

9.0 Target Analytes (CLP Form I Equivalent)

9.1 Are the Organic Analysis reporting forms present with required header information on each page, for each of the following:

a. Samples and/or fractions as appropriate

b. Matrix spikes and matrix spike duplicates

c. Blanks

d. Laboratory Control Samples

STANDARD OPERATING PROCEDURE

YES NO N/A

9.2 Are the Reconstructed Ion Chromatograms, mass spectra for the identified compounds, and the data system printouts (Quant Reports) included in the sample package for each of the following?

- a. Samples and/or fractions as appropriate ___ ___
- b. Matrix spikes and matrix spike duplicates (Mass spectra not required) ___ ___
- c. Blanks ___ ___
- d. Laboratory Control Samples ___ ___

ACTION: If any data are missing, take action specified in 3.2 above.

9.3 Are the response factors shown in the Quant Report?

___ ___

9.4 Is chromatographic performance acceptable with respect to:

- Baseline stability? ___ ___
- Resolution? ___ ___
- Peak shape? ___ ___
- Full-scale graph (attenuation)? ___ ___
- Other: _____ ___ ___

ACTION: Use professional judgement to determine the acceptability of the data.

9.5 Are the lab-generated standard mass spectra of identified volatile compounds present for each sample?

___ ___

ACTION: If any mass spectra are missing, take action specified in 3.2 above. If the lab does not generate their own standard spectra, make a note in the Data Assessment. If spectra are missing, reject all positive data.

9.6 Is the RRT of each reported compound within 0.06 RRT units of the standard RRT in the continuing calibration?

___ ___

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

9.7 Are all ions present in the standard mass spectrum at a relative intensity greater than 10% (of the most abundant ion) also present in the sample mass spectrum?

9.8 Do the relative intensities of the characteristic ions in the sample agree within ± 30% of the corresponding relative intensities in the reference spectrum?

[] ___ ___

ACTION: Use professional judgement to determine acceptability of data. If it is determined that incorrect identifications were made, all such data should be rejected ("R"), flagged ("N") - Presumptive evidence of the presence of the compound) or changed to non detected ("U") at the calculated detection limit. In order to be positively identified, the data must comply with the criteria listed in 9.6, 9.7, and 9.8.

ACTION: When sample carry-over is a possibility, professional judgement should be used to determine if instrument cross-contamination has affected any positive compound identification.

10.0 Tentatively Identified Compounds (TIC) (CLP Form I/TIC Equivalent)

10.1 If Tentatively Identified Compound were required for this project, are all Tentatively Identified Compound reporting forms present; and do listed TICs include scan number or retention time, estimated concentration and a qualifier?

[] ___ ___

NOTE: Add "N" qualifier to all TICs which have CAS number, if missing.

NOTE: Have the project officer/appropriate official check the project plan to determine if lab was required to identify non-target analytes (SW-846, page 8260B-23, Sect. 7.6.2).

10.2 Are the mass spectra for the tentatively identified compounds and associated "best match" spectra included in the sample package for each of the following:

a. Samples and/or fractions as appropriate

[] ___ ___

b. Blanks

[] ___ ___

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S))Q
YES NO N/A

ACTION: If any TIC data are missing, take action specified in 3.2 above.

ACTION: Add "JN" qualifier only to analytes identified by a CAS#.

NOTE: If TICs are present in the associated blanks take action as specified in section 6.2 above.

10.3 Are any priority pollutants listed as TIC compounds (i.e., an BNA compound listed as a VOA TIC)?

ACTION: 1. Flag with "R" any target compound listed as a TIC.
2. Make sure all rejected compounds are properly reported if they are target compounds.

10.4 Are all ions present in the reference mass spectrum with a relative intensity greater than 10% (of the most abundant ion) also present in the sample mass spectrum?

10.5 Do TIC and "best match" standard relative ion intensities agree within $\pm 20\%$?

ACTION: Use professional judgement to determine acceptability of TIC identifications. If it is determined that an incorrect identification was made, change the identification to "unknown" or to some less specific identification (example: "C3 substituted benzene") as appropriate. Also, when a compound is not found in any blank, but is a suspected artifact of a common laboratory contaminant, the result should be qualified as unusable, "R". (Common lab contaminants: CO₂(M/E 44), Siloxanes (M/E 73), Hexane, Aldol Condensation Products, Solvent Preservatives, and related byproducts).

11.0 Compound Quantitation and Reported Detection Limits

11.1 Are there any transcription/calculation errors in organic analysis reporting form results? Check at least two positive values. Verify that the correct internal standard, quantitation ion, and average initial RRF/CF were used to calculate organic analysis reporting form result. Were any errors found?

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S))Q
YES NO N/A

NOTE: Structural isomers with similar mass spectra, but insufficient GC resolution (i.e. percent valley between the two peaks > 25%) should be reported as isomeric pairs. The reviewer should check the raw data to ensure that all such isomers were included in the quantitation (i.e., add the areas of the two coeluting peaks to calculate the total concentration).

11.2 Are the method CRQL's adjusted to reflect sample dilutions and, for soils, sample moisture? ___ ___

ACTION: If errors are large, take action as specified in section 3.2 above.

ACTION: When a sample is analyzed at more than one dilution, the lowest detection limits are used (unless a QC exceedance dictates the use of the higher detection limit from the diluted sample data). Replace concentrations that exceed the calibration range in the original analysis by crossing out the "E" and it's associated value on the original reporting form (if present) and substituting the data from the analysis of the diluted sample. Specify which organic analysis reporting form is to be used, then draw a red "X" across the entire page of all reporting forms that should not be used, including any in the summary package.

12.0 Standards Data (GC/MS)

12.1 Are the Reconstructed Ion Chromatograms, and data system printouts (Quant Reports) present for initial and continuing calibration? ___ ___

ACTION: If any calibration standard data are missing, take action specified in section 3.2 above.

13.0 GC/MS Initial Calibration (CLP Form VI Equivalent)

13.1 Are the Initial Calibration reporting forms present and complete for the volatile fraction? ___ ___

ACTION: If any calibration forms or standard raw data are missing, take action specified in section 3.2 above.

STANDARD OPERATING PROCEDURE

US EPA Region II
SW-846 Method 8260B (Rev 2, Dec 1996)

Date: June 1999
SOP HW-24, Rev. 1

S))
YES NO N/A

13.2 Are all average RRFs > 0.050?

NOTE: (Method Requirement) For SPCC compounds, the individual RRF values must be the values in the following list. If individual RRF values reported are below the listed values document in the Data Assessment.

Chloromethane	0.10
1,1-Dichloroethane	0.10
Bromoform	0.10
Chlorobenzene	0.30
1,1,2,2-Tetrachloroethane	0.30

ACTION: Circle all outliers with red pencil.

ACTION: For any target analyte with average RRF < 0.05, qualify all positive results for that analyte "J" and all non-detect results for that analyte "R".

NOTE: The above data qualification action applies regardless of method requirements.

[] _ _

13.3 Are response factors stable over the concentration range of the calibration. The % relative standard deviation (%RSD) 15.0% as per SW-846, 8260B-17 Sect. 7.3.6.2.

NOTE: (Method Requirement) For the following CCC compounds, the %RSD values must be 30.0%. If %RSD values reported are > 30.0% document in the Data Assessment.

- 1,1-Dichloroethene
- Chloroform
- 1,2-Dichloropropane
- Toluene
- Ethylbenzene
- Vinyl chloride

ACTION: Circle all outliers with a red pencil.

ACTION: If the % RSD is > 15.0%, qualify positive results for that analyte "J" and non-detects using professional judgement. When RSD > 90%, qualify all positive results for that analyte "J" and all non-detect results for that analyte "R".

NOTE: The above data qualification action applies regardless of method requirements.

NOTE:
Analytes previously qualified "U" due to blank

SOP	-	standard operating procedure
SPCC	-	system performance check compound
TIC	-	tentatively identified compound
TCLP	-	toxicity characteristic leach procedure
ug	-	micrograms
VOA	-	volatile organic acid

DEFINITIONS

Data Qualified Definitions:

- U - The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
- J - The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
- N - The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification".
- NJ - The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.
- UJ - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
- R - The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

INTRODUCTION

This document is designed to offer the data reviewer guidance in determining the validity of analytical data generated through the USEPA Contract Laboratory Program (CLP) Statement of Work (SOW) ISM01.X Inorganic Superfund Methods (Multi-Media, Multi-Concentration), hereinafter referred to as the ISM01.2 SOW, and any future editorial revisions of ISM01.2. This guidance is somewhat limited in scope and is intended to be used as an aid in the formal technical review process.

The guidelines presented in the document will aid the data reviewer in establishing (a) if data meets the specific technical and QC criteria established in the SOW, and (b) the validity and extent of bias of any data not meeting the specific technical and QC criteria established in the SOW. It must be understood by the reviewer that acceptance of data not meeting technical requirements is based upon many factors, including, but not limited to site-specific technical requirements, the need to facilitate the progress of specific projects, and availability for re-sampling.

The reviewer should note that while this document is to be used as an aid in the formal data review process, other sources of guidance and information, as well as **professional judgment**, should also be used to determine the ultimate validity of data, especially in those cases where all data does not meet specific technical criteria.

DATA QUALIFIER DEFINITIONS

The following definitions provide brief explanations of the national qualifiers assigned to results in the data review process.

U	The analyte was analyzed for, but was not detected above the level of the reported sample quantitation limit.
J	The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.
J+	The result is an estimated quantity, but the result may be biased high.
J-	The result is an estimated quantity, but the result may be biased low.
R	The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.
UJ	The analyte was analyzed for, but was not detected. The reported quantitation limit is approximate and may be inaccurate or imprecise.

DATA PACKAGE INSPECTION

For data obtained through the Contract Laboratory Program (CLP), the EXES Data Manager (EDM) is a useful tool in the data review process. For more information about EDM, please refer to the following Sample Management Office (SMO) website:

<https://epasmoweb.fedcsc.com/help/guides/Submit%20and%20Inspect%20Data%20Quick%20Guide%20%28EXES%29.pdf>

EDM will identify any missing and/or incorrect information in the data package. The CLP laboratory may submit a reconciliation package for any missing items or to correct data. If there are any concerns regarding the data package, contact the CLP Project Officer (CLP PO) from the Region where the samples were taken. For personnel contact information, please refer to the following CLP website:

<http://www.epa.gov/superfund/programs/clp/contacts.htm>

HWSS DATA VALIDATION PROCESS

After downloading the data package from EDM, the data validator will use the recommendations in this SOP as well as their own professional judgment to validate the data.

The data will be saved in the following location, under the appropriate case number folder:

G:\DESADIV\HWSS\DATA VALIDATION

The file naming conventions will consist of

- | | |
|----------------------------------|--------------|
| A. case number | i.e., 12345 |
| B. SDG name | i.e., MBXY12 |
| C. level of validation performed | i.e., S2BVE |

Examples: **12345_MBXY12_S2BVE.xls**

12345_MBXY12_S2BVEM.xls

When data validation is completed, the data package is uploaded for the client to download from the HWSS data delivery website:

<https://epaqpx.rtp.epa.gov/hwssclpdeliverables>

The completed data package includes the Executive Narrative (see Appendix B for template), the Sample Summary Report (see Appendix C for example), and the Electronic Data Deliverable (EDD) (see Appendix D for a list of the column headers included in this document).

PRELIMINARY REVIEW

This document is for the review of analytical data generated through the ISM01.2 SOW and any future editorial revisions of ISM01.2. To use this document effectively, the reviewer should have an understanding of the analytical method and a general overview of the Sample Delivery Group (SDG) or sample Case at hand. The exact number of samples, their assigned numbers, their matrix, and the number of laboratories involved in the analysis are essential information.

It is suggested that an initial review of the data package be performed, taking into consideration all information specific to the sample data package [e.g., Modified Analysis requests, Traffic Report/Chain of Custody (TR/COC) documentation, SDG Narratives, etc.].

The reviewer should also have a copy of the Quality Assurance Project Plan (QAPP) or similar document for the project for which the samples were analyzed. The reviewer should contact the appropriate Regional Contract Laboratory Program Project Officer (CLP PO) to obtain copies of the QAPP and relevant site information. This information is necessary in determining the final usability of the analytical data.

The SDGs or Cases routinely have unique samples that require special attention from the reviewer. These include field blanks and trip blanks, field duplicates, and Performance Evaluation (PE) samples which must be identified in the sampling records. The sampling records (e.g., TR/COC records, field logs, and/or contractor tables) should identify:

1. The Region where the samples were taken, and
2. The complete list of samples with information on:
 - a. Sample matrix;
 - b. Field blanks*;
 - c. Field duplicates*;
 - d. Field spikes*;
 - e. PE samples*;
 - f. Shipping dates;
 - g. Preservatives;
 - h. Types of analysis; and
 - i. Laboratories involved.

* If applicable.

The TR/COC documentation includes sample descriptions and date(s) of sampling. The reviewer must consider lag times between sampling and start of analysis when assessing technical sample holding times.

The laboratory's SDG Narrative is another source of general information. Notable problems with matrices, insufficient sample volume for analysis or reanalysis, samples received in broken containers, preservation, and unusual events should be documented in the SDG Narrative. The reviewer should also inspect any email or telephone/communication logs detailing any discussion of sample or analysis issues between the laboratory, the CLP Sample Management Office (SMO), and the USEPA Region.

Mercury Preservation and Holding Times

Action:

NOTE: Apply the action to each sample for which the preservation or holding time criteria was not met.

1. If the pH of aqueous/water metal samples is > 2 at the time of sample receipt, determine if the laboratory adjusted the pH of the sample to ≤ 2 at the time of sample receipt. If not, use professional judgment to qualify the samples based on the pH of the sample and the chemistry of the metal(s) of interest. Qualify results that are \geq Method Detection Limit (MDL) as estimated low (J-), and qualify non-detects as unusable (R).
2. If technical holding times are exceeded, use professional judgment to determine the reliability of the data, based on the magnitude of the additional time compared to the technical requirement and whether the samples were properly preserved. The expected bias would be low. Qualify results that are \geq MDL as estimated low (J-), and qualify non-detects as unusable (R).
3. Due to limited information concerning holding times for soil/sediment samples, it is left to the discretion of the data reviewer whether to apply aqueous/water holding time criteria to soil/sediment samples. If they are applied, it must be clearly documented in the Data Review Narrative.
4. When the holding times are exceeded, the reviewer should comment in the Data Review Narrative on any possible consequences for the analytical results.
5. When holding times are grossly exceeded, note it for Contract Laboratory Program Project Officer (CLP PO) action.

Table 1. Technical Holding Time Actions for Mercury Analysis

Preservation & Holding Time Results	Action for Samples
Aqueous/water mercury samples received with pH > 2 and pH not adjusted	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Aqueous/water samples > 28 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Soil/sediment samples > 28 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

Cyanide Preservation and Holding Times

Action:

NOTE: Apply the action to each sample for which the preservation or holding time criteria was not met.

1. If oxidizing agents are detected in aqueous/water cyanide samples at the time of sample preparation, qualify results that are \geq Method Detection Limit (MDL) as estimated low (J-) and non-detects as unusable (R). If sulfides are detected in aqueous/water cyanide samples at the time of sample preparation and there is no evidence that the laboratory removed the sulfides (using precipitation and filtration), qualify results that are \geq MDL as estimated (J) and non-detects as unusable (R). If the pH of aqueous/water cyanide samples is < 12 at the time of sample receipt, use professional judgment to qualify the samples based on the pH of the sample. Qualify results that are \geq MDL as estimated low (J-) and qualify non-detects as unusable (R).
2. If technical holding times are exceeded, use professional judgment to determine the reliability of the data based on the magnitude of the additional time compared to the technical requirement and whether the samples are properly preserved. The expected bias would be low. Qualify results that are \geq MDL as estimated low (J-) and non-detects as unusable (R).
3. Due to limited information concerning holding times for soil/sediment samples, it is left to the discretion of the data reviewer whether to apply aqueous/water holding time criteria to soil/sediment samples. If they are applied, it must be clearly documented in the Data Review Narrative.
4. When the holding times are exceeded, the reviewer should comment in the Data Review Narrative on any possible consequences for the analytical results.
5. When holding times are grossly exceeded, note it for Contract Laboratory Program Project Officer (CLP PO) action.

Table 2. Technical Holding Time Actions for Cyanide Analysis

Preservation & Holding Time Results	Action for Samples
Aqueous/water cyanide samples received with oxidizing agents present	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Aqueous/water cyanide samples received with sulfides present, and sulfides are not removed	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as unusable (R)
Aqueous/water cyanide samples received with pH < 12	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Cyanide > 14 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

Mercury Calibration

Table 3. Acceptance Criteria for Mercury ICVs and CCVs

Analytical Method	Inorganic Analytes	ICV/CCV Low Limit (% of True Value)	ICV/CCV High Limit (% of True Value)
Cold Vapor AA	Mercury	85	115

Action:

NOTES: For initial calibrations or ICVs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.
For CCVs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the QC sample and a subsequent technically acceptable analysis of the QC sample in the analytical run.

NOTE: The data validator shall verify the correlation coefficient by calculating it using the standard concentrations and the corresponding instrument response.

1. If the instrument was not calibrated daily and each time the instrument was set up or an ICV standard was not analyzed before field and QC samples, qualify the data as unusable (R). If the instrument was not calibrated with a blank and at least 5 calibration standards, or if the instrument was not calibrated with standards prepared at the same time as the samples, use professional judgment to qualify results that are \geq Method Detection Limit (MDL) as estimated (J), and non-detects as estimated (UJ). If the calibration curve does not include standards at required concentrations (e.g., a blank and at least one standard at or below CRQL), use professional judgment to qualify results that are \geq MDL as estimated (J), and non-detects as estimated (UJ).
2. If the correlation coefficient is < 0.995 , percent differences are outside the $\pm 30\%$ limit, or the y-intercept \geq CRQL, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ). If the correlation coefficient is < 0.990 , qualify results that are \geq MDL as estimated (J) and non-detects as unusable (R).
3. If the ICV or CCV %R falls outside the acceptance windows, use professional judgment to qualify all associated data. If possible, indicate the bias in the review. The following guidelines are recommended:
 - a. If the ICV or CCV %R is $< 70\%$, qualify non-detects as unusable (R). Use professional judgment to qualify all results that are \geq MDL as unusable (R).
 - b. If the ICV or CCV %R falls within the range of 70-84%, qualify sample results that are \geq MDL as estimated low (J-), and qualify non-detects as estimated (UJ).
 - c. If the ICV or CCV %R falls within the range of 116-130%, qualify sample results that are \geq MDL as estimated high (J+).
 - d. If the ICV or CCV %R is within the range of 116-130%, non-detects should not be qualified.
 - e. If the ICV or CCV %R is $> 130\%$, use professional judgment to qualify results that are \geq MDL as estimated high (J+). Non-detects should not be qualified.

- f. If the %R is > 165%, qualify all results that are \geq MDL as unusable (R).
4. If the laboratory failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
 5. Note the potential effects on the reported data due to exceeding the calibration criteria in the Data Review Narrative.
 6. If calibration criteria are grossly exceeded, note this for CLP Project Officer (CLP PO) action.

NOTE: For critical samples, a further in-depth evaluation of the calibration curve may be warranted to determine if additional qualification is necessary.

Table 4. Calibration Actions for Mercury Analysis

Calibration Result	Action for Samples
Calibration not performed	Qualify all results as unusable (R)
Calibration incomplete	Use professional judgment Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Not at least one calibration standard at or below the CRQL for each analyte	Qualify results that are \geq MDL but < 2x the CRQL as estimated (J) Qualify non-detects as estimated (UJ)
Correlation coefficient < 0.995; %D outside $\pm 30\%$; y-intercept \geq CRQL	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Correlation coefficient < 0.990	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as unusable (R)
ICV/CCV %R < 70%	Qualify results that are \geq MDL as unusable (R) Qualify all non-detects as unusable (R)
ICV/CCV %R 70-84%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICV/CCV %R 116-130%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R > 130%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R > 165%	Qualify results that are \geq MDL as unusable (R)

Cyanide Calibration

Table 5. Acceptance Criteria for Cyanide ICVs and CCVs

Analytical Method	Inorganic Analytes	ICV/CCV Low Limit (% of True Value)	ICV/CCV High Limit (% of True Value)
Colorimetric	Cyanide	85	115

Action:

NOTES: For initial calibrations or ICVs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.
For CCVs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the QC sample and a subsequent technically acceptable analysis of the QC sample in the analytical run.

NOTE: The data validator shall verify the correlation coefficient by calculating it using the standard concentrations and the corresponding instrument response.

1. If the instrument was not calibrated daily and each time the instrument was set up or an ICV standard was not analyzed before field and QC samples, qualify the data as unusable (R). If the instrument was not calibrated with a blank and at least 5 calibration standards, or if the instrument was not calibrated with standards prepared at the same time as the samples, use professional judgment to qualify results that are \geq Method Detection Limit (MDL) as estimated (J), and non-detects as estimated (UJ). If the calibration curve does not include standards at required concentrations (e.g., a blank and at least one standard at or below CRQL), use professional judgment to qualify results that are \geq MDL as estimated (J), and non-detects as estimated (UJ).
2. If the correlation coefficient is < 0.995 , percent differences are outside the $\pm 30\%$ limit, or the y-intercept \geq CRQL, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ). If the correlation coefficient is < 0.990 , qualify results that are \geq MDL as estimated (J) and non-detects as unusable (R).
3. If the standards, the ICV, or the CCVs are not distilled for cyanide, qualify sample results that are \geq MDL as estimated (J).
4. If the ICV or CCV %R falls outside the acceptance windows, use professional judgment to qualify all associated data. If possible, indicate the bias in the review. The following guidelines are recommended:
 - a. If the ICV or CCV %R is $< 70\%$, qualify non-detects as unusable (R). Use professional judgment to qualify all results that are \geq MDL as unusable (R).
 - b. If the ICV or CCV %R falls within the range of 70-84%, qualify sample results that are \geq MDL as estimated low (J-), and qualify non-detects as estimated (UJ).
 - c. If the ICV or CCV %R falls within the range of 116-130%, qualify sample results that are \geq MDL as estimated high (J+).
 - d. If the ICV or CCV %R is within the range of 116-130%, non-detects should not be qualified.

- e. If the ICV or CCV %R is > 130%, use professional judgment to qualify results that are \geq MDL as estimated high (J+). Non-detects should not be qualified.
- f. If the %R is > 165%, qualify all results that are \geq MDL as unusable (R).
- 5. If the laboratory failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
- 6. Note the potential effects on the reported data due to exceeding the calibration criteria in the Data Review Narrative.
- 7. If calibration criteria are grossly exceeded, note this for CLP Project Officer (CLP PO) action.

NOTE: For critical samples, a further in-depth evaluation of the calibration curve may be warranted to determine if additional qualification is necessary.

Table 6. Calibration Actions for Cyanide Analysis

Calibration Result	Action for Samples
Calibration not performed	Qualify all results as unusable (R)
Calibration incomplete	Use professional judgment Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Not at least one calibration standard at or below the CRQL for each analyte	Qualify results that are \geq MDL but < 2x the CRQL as estimated (J) Qualify non-detects as estimated (UJ)
Correlation coefficient < 0.995; %D outside $\pm 30\%$; y-intercept \geq CRQL	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Correlation coefficient < 0.990	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as unusable (R)
Standards and QC not distilled	Qualify results that are \geq MDL as estimated (J)
ICV/CCV %R < 70%	Qualify results that are \geq MDL as unusable (R) Qualify all non-detects as unusable (R)
ICV/CCV %R 70-84%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICV/CCV %R 116-130%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R > 130%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R > 165%	Qualify results that are \geq MDL as unusable (R)

Mercury/Cyanide Calibration/Preparation Blanks

Action:

NOTES: For ICBs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCBs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the CCB and a subsequent technically acceptable analysis of the CCB in the analytical run.

For Preparation Blanks that do not meet the technical criteria, apply the action to all samples prepared in the same preparation batch.

NOTES: The preparation blank for mercury is the same as the calibration blank.

Convert soil sample result to mg/kg on wet weight basis to compare with the soil preparation result on Form III.

Associated samples are all samples digested with the preparation blank.

1. If the appropriate blanks were not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank (including Preparation Blanks) reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank (including Preparation Blanks) reported with a negative result, whose value is $<$ (-CRQL) qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. Specific “method” actions include:
 - a. If the absolute value of an ICB or a CCB result is $>$ CRQL, the analysis should be terminated. If the analysis was not terminated and the affected samples were not reanalyzed, report non-detects and results that are \geq MDL, but \leq CRQL as CRQL-U. For results that are $>$ CRQL but $<$ Blank Result, report the results at the level of the blank with a “U” qualifier. Use professional judgment to qualify results that

- are > Blank Result. Note this situation for CLP PO action and record it in the Data Review Narrative.
- b. If the absolute value of the concentration of the Preparation Blank is \leq CRQL, report non-detects and results that are \geq MDL but \leq CRQL as CRQL-U. Use professional judgment to quality results that are > CRQL.
 - c. If the mercury concentration in the Preparation Blank is > CRQL, the lowest concentration of mercury in the associated samples must be 10x the Preparation Blank concentration. Otherwise, all samples associated with that blank with concentrations < 10x the Preparation Blank concentration and > CRQL should be redigested and reanalyzed. Raise the CRQL to the concentration found in the Preparation Blank and report those samples that do not require redigestion (that are \geq MDL but \leq CRQL) as CRQL-U. Note for CLP PO action and record in the Data Review Narrative if the laboratory failed to redigest and reanalyze the affected samples. The reviewer shall then use professional judgment to assess the data.
 - d. If the cyanide concentration in the Preparation Blank is > CRQL, the lowest concentration of cyanide in the associated samples must be 10x the Preparation Blank concentration. Otherwise, all samples associated with that blank with concentrations < 10x the Preparation Blank concentration and > CRQL should be redistilled and reanalyzed. Raise the CRQL to the concentration found in the Preparation Blank and report those samples that do not require redistillation (that are \geq MDL but \leq CRQL) as CRQL-U. Note for CLP PO action and record in the Data Review Narrative if the laboratory failed to redistill and reanalyze the affected samples. The reviewer shall then use professional judgment to assess the data.

Table 7. Calibration/Preparation Blank Actions for Mercury/Cyanide Analysis

Blank Type	Blank Result	Sample Result	Action for Samples
ICB/CCB	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
ICB/CCB	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ Blank Result	Report at level of Blank Result with a "U"
		$>$ Blank Result	Use professional judgment
ICB/CCB	\leq (-MDL) but \geq (-CRQL)	\geq MDL, or non-detect	Use professional judgment
ICB/CCB	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)
Preparation Blank	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ 10x the Blank Result	Qualify results as estimated high (J+)
		\geq 10x the Blank Result	No action
Preparation Blank	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
Preparation Blank	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)

Mercury/Cyanide Laboratory Duplicate Sample Analysis

Action:

NOTE: For a duplicate sample analysis that does not meet the technical criteria, apply the action to only the field sample used to prepare the duplicate sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

NOTE: Delete “*” from Form IAs.

If one value is > CRQL and the other value is non-detect, calculate the absolute difference between the value > CRQL and the MDL and use this difference to qualify sample results.

If more than one lab duplicate sample was analyzed for an SDG, then qualify the associated samples based on the worst lab duplicate analysis.

1. If the appropriate number of duplicate samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for CLP Project Officer (CLP PO) action.
2. If the results from a duplicate analysis for mercury/cyanide fall outside the control limits for > 5x the CRQL, qualify aqueous sample results that are \geq CRQL as estimated (J) if the RPD is between 20% - 100% and as unusable (R) if the RPD is > 100%. Qualify soil/sediment sample results that are \geq CRQL as estimated (J) if the RPD is between 35% - 120% and as unusable (R) if the RPD is > 120%.
3. If the results from a duplicate analysis for mercury/cyanide fall outside the control limits for \leq 5x the CRQL, qualify those results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
4. If a field blank or PE sample was used for the duplicate sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
5. Note the potential effects on the data due to out-of-control duplicate sample results in the Data Review Narrative.

Table 8. Duplicate Sample Actions for Mercury/Cyanide Analysis

Duplicate Sample Results	Action for Samples
<i>Aqueous:</i> Both original sample and duplicate sample > 5x the CRQL and 20% < RPD < 100%	Qualify those results that are \geq CRQL as estimated (J)
<i>Aqueous:</i> Both original sample and duplicate sample > 5x the CRQL and RPD \geq 100%	Qualify those results that are \geq CRQL as unusable (R)
<i>Soil/Sediment:</i> Both original sample and duplicate sample > 5x the CRQL and 35% < RPD < 120%	Qualify those results that are \geq CRQL as estimated (J)
<i>Soil/Sediment:</i> Both original sample and duplicate sample > 5x the CRQL and RPD \geq 120%	Qualify those results that are \geq CRQL as unusable (R)
Original sample or duplicate sample \leq 5x the CRQL (including non-detects) and absolute difference between sample and duplicate > CRQL	Qualify those results that are \geq MDL as estimated (J) and non-detects as estimated (UJ)

Mercury Spike Sample Analysis

Action:

- NOTE:** For a Matrix Spike that does not meet the technical criteria, apply the action to only the field sample used to prepare the Matrix Spike sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.
- NOTE:** The final spike concentrations required for mercury are presented in the methods described in the Statement of Work (SOW).
- NOTE:** When the sample concentration is < Method Detection Limit (MDL), use SR = 0 only for the purpose of calculating the %R. The actual spiked sample results, sample results, and %R (positive or negative) shall still be reported on Forms VA-IN and VB-IN.
- NOTES:** Disregard the out of control spike recoveries for analytes whose unspiked concentrations are $\geq 4x$ the spike added.
Delete "N" from Form IAs.
1. If the appropriate number of Matrix Spike samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for Contract Laboratory Program Project Officer (CLP PO) action.
 2. If a field blank or PE sample was used for the spiked sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
 3. If the Matrix Spike %R is < 30%, qualify affected results that are \geq MDL as estimated low (J-) and non-detects as unusable (R).
 4. If the Matrix Spike %R falls within the range of 30-74% and the sample results are \geq MDL, qualify the affected data as estimated low (J-).
 5. If the Matrix Spike %R falls within the range of 30-74% and the sample results are non-detects, qualify the affected data as estimated (UJ).
 6. If the Matrix Spike %R is > 125% and the reported sample results are non-detects, the sample data should not be qualified.
 7. If the Matrix Spike %R is > 125% and the sample results are \geq MDL, qualify the affected data as estimated high (J+).
 8. Note the potential effects on the data due to out-of-control spiked sample results in the Data Review Narrative.

Table 9. Spike Sample Actions for Mercury Analysis

Spike Sample Results	Action for Samples
Matrix Spike %R < 30%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R 30-74%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R > 125%	Qualify affected results that are \geq MDL as estimated high (J+) Non-detects are not qualified

Cyanide Spike Sample Analysis

Action:

- NOTE:** For a Matrix Spike that does not meet the technical criteria, apply the action to only the field sample used to prepare the Matrix Spike sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.
- NOTE:** The final spike concentrations required for cyanide are presented in the methods described in the Statement of Work (SOW).
- NOTE:** When the sample concentration is < Method Detection Limit (MDL), use SR = 0 only for the purpose of calculating the %R. The actual spiked sample results, sample results, and %R (positive or negative) shall still be reported on Forms VA-IN and VB-IN.
- NOTES:** Disregard the out of control spike recoveries for analytes whose unspiked concentrations are $\geq 4x$ the spike added.
Delete "N" from Form IAs.
1. If the appropriate number of Matrix Spike samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for Contract Laboratory Program Project Officer (CLP PO) action.
 2. If a field blank or PE sample was used for the spiked sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
 3. If the Matrix Spike recovery does not meet the evaluation criteria and a required post-distillation spike was not performed, note this for CLP PO action.
 4. If the Matrix Spike %R is < 30%, verify that a post-distillation spike was analyzed if required. If the post-distillation spike %R is < 75% or is not performed, qualify sample results that are \geq MDL as estimated low (J-) and non-detects as unusable (R). If the post-distillation spike %R is $\geq 75%$, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
 5. If the Matrix Spike %R falls within the range of 30-74% and the sample results are \geq MDL, verify that a post-distillation spike was analyzed if required. If the %R for the post-distillation spike is also < 75% or not performed, qualify the affected data as estimated low (J-). If the %R for the post-distillation spike is $\geq 75%$, qualify the affected data as estimated (J).
 6. If the Matrix Spike %R falls within the range of 30-74% and the sample results are non-detects, qualify the affected data as estimated (UJ).
 7. If the Matrix Spike %R is > 125% and the reported sample results are non-detects, the sample data should not be qualified.
 8. If the Matrix Spike %R is > 125% and the sample results are \geq MDL, verify that a post-distillation spike was analyzed if required. If the %R for the post-distillation spike is also

> 125% or is not performed, qualify the affected data as estimated high (J+). If the %R for the post-distillation spike is \leq 125%, qualify the affected data as estimated (J).

9. Note the potential effects on the data due to out-of-control spiked sample results in the Data Review Narrative.

Table 10. Spike Sample Actions for Cyanide Analysis

Spike Sample Results	Action for Samples
Matrix Spike %R < 30% Post-distillation spike %R < 75%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R < 30% Post-distillation spike %R \geq 75%	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-distillation Spike %R < 75%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-distillation spike %R \geq 75%	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R > 125% Post-distillation spike %R > 125%	Qualify affected results that are \geq MDL as estimated high (J+)
Matrix Spike %R > 125% Post-distillation spike %R \leq 125%	Qualify affected results that are \geq MDL as estimated (J)
Matrix Spike %R < 30% No post-distillation spike performed	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R 30-74% No post-distillation spike performed	Qualify affected results that are \geq MDL as estimated low (J-) and non-detects as estimated (UJ)
Matrix Spike %R > 125% No post-distillation spike performed	Qualify affected results that are \geq MDL as estimated high (J+) Non-detects are not qualified

Mercury/Cyanide Field Duplicates

Action:

NOTES: For field duplicates that do not meet the technical criteria, apply the action to only the field sample and its duplicate. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

Check the Sampling Trip Report for the field duplicate pair.

Substitute MDL for CRQL when MDL > CRQL.

Do not calculate RPD when both values are non-detects.

If one value is > the CRQL and the other value is non-detect, calculate the absolute difference between the value > the CRQL and the MDL, and use this criteria to qualify the results.

1. If a field duplicate pair was collected and analyzed, calculate and report the RPD when the sample and its field duplicate values are both $\geq 5x$ the CRQL. Calculate and report the absolute difference when at least one value (sample or duplicate) is $< 5x$ the CRQL.
2. When aqueous sample and duplicate values are both $\geq 5x$ the CRQL, and the RPD is $> 20\%$, qualify the sample and its duplicate as estimated (J).
3. When aqueous sample and/or the duplicate value is $< 5x$ the CRQL, and the absolute difference is $>$ the CRQL, qualify results $>$ the MDL as estimated (J) and non-detects as estimated (UJ).
4. When soil/sediment sample and duplicate values are both $\geq 5x$ the CRQL, and the RPD is $> 50\%$, qualify the sample and its duplicate as estimated (J).
5. When soil/sediment sample and/or the duplicate value is $< 5x$ the CRQL, and the absolute difference is $> 2x$ the CRQL, qualify results $>$ the MDL as estimated (J) and non-detects as estimated (UJ).

Table 11. Field Duplicate Actions for Mercury/Cyanide Analysis

Sample Type	Field Duplicate Result	Action for Samples
Aqueous	Sample and its field duplicate $\geq 5x$ the CRQL and RPD $> 20\%$	Qualify sample and its duplicate as estimated (J)
	Sample and/or its field duplicate $< 5x$ the CRQL and absolute difference $>$ the CRQL	Qualify results $>$ the MDL as estimated (J) Qualify non-detects as estimated (UJ)
Soil/Sediment	Sample and its field duplicate $\geq 5x$ the CRQL and RPD $> 50\%$	Qualify sample and its duplicate as estimated (J)
	Sample and/or its field duplicate $< 5x$ the CRQL and absolute difference $> 2x$ the CRQL	Qualify results $>$ the MDL as estimated (J) Qualify non-detects as estimated (UJ)

Mercury/Cyanide Field/Rinsate/Trip Blanks

Action:

NOTE: Designate “Field Blank” as such on Form IA.
Field Blank results previously rejected due to other criteria cannot be used to qualify field samples.
Do not use Rinsate Blank associated with soils to qualify water samples and vice versa.

If the MDL is > the CRQL, substitute CRQL with 2x the MDL.

1. If the appropriate blanks were not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank reported with a negative result, whose value is $<$ (-CRQL) qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. If the absolute value of mercury/cyanide in a Field/Rinsate/Trip Blank is > the CRQL, then the CRQL shall be raised to the level in the Field/Rinsate/Trip Blank and the associated sample data below this level shall be reported as CRQL-U.
5. Sample results > the Field/Rinsate/Trip Blank value but < 10x the Field/Rinsate/Trip Blank value shall be qualified as estimated (J).
6. Sample results \geq the MDL but \leq the CRQL shall be reported at the CRQL value with a “U”.

Table 12. Field/Rinsate/Trip Blank Actions for Mercury/Cyanide Analysis

Blank Result	Sample Result	Action for Samples
> CRQL	\geq MDL but \leq CRQL	Report CRQL value with a “U”
	> CRQL but < Blank Result	Report at level of Blank Result with a “U”
	> Blank Result but < 10x the Blank Result	Use professional judgment to qualify results as estimated (J)

Mercury/Cyanide Linear Ranges

Action:

1. If any sample result was higher than the highest calibration standard for mercury/cyanide and the sample was not diluted to obtain the result reported on Form I, qualify the affected results \geq MDL as estimated (J).

Mercury/Cyanide Percent Solids of Sediments

Action:

1. If the percent solids in sediment for a sample are $< 50\%$, qualify the affected results \geq MDL as estimated (J) and the non-detects as estimated (UJ).

Regional Quality Assurance (QA) and Quality Control (QC)

Action:

Any action must be in accordance with Regional specifications and criteria for acceptable PE sample results. Note any unacceptable PE sample results for Contract Laboratory Program Project Officer (CLP PO) action.

Overall Assessment

Action:

1. Use professional judgment to determine if there is any need to qualify data which were not qualified based on the QC criteria previously discussed.
2. Write a brief Data Review Narrative to give the user an indication of the analytical limitations of the data. Note any discrepancies between the data and the Sample Delivery Group (SDG) Narrative for Contract Laboratory Program Project Officer (CLP PO) action. If sufficient information on the intended use and required quality of the data is available, the reviewer should include an assessment of the data usability within the given context.
3. If any discrepancies are found, the laboratory may be contacted by the Region's designated representative to obtain additional information for resolution. If a discrepancy remains unresolved, the reviewer may determine that qualification of the data is warranted.

Calculations for Mercury

Aqueous/Water Samples:

$$Hg \text{ Concentration } \left(\frac{\mu g}{L} \right) = C \times DF$$

Where,

- C = Instrument value in $\mu\text{g/L}$ from the calibration curve
DF = Dilution Factor

Soil/Sediment Samples:

$$Hg \text{ Concentration } \left(\frac{mg}{kg} \right) = C \times \frac{1}{W \times S} \times \frac{DF}{10}$$

Where,

- C = Instrument value in $\mu\text{g/L}$ from the calibration curve
W = Initial aliquot amount (g)
S = % Solids/100 (see Exhibit D of ISM01.2 - Introduction to Analytical Methods, Section 1.6).
DF = Dilution Factor

Adjusted Method Detection Limit (MDL)/Adjusted Contract Required Quantitation Limit (CRQL) Calculation:

To calculate the adjusted MDL or adjusted CRQL for aqueous/water samples, multiply the value of the MDL ($\mu\text{g/L}$) or CRQL ($\mu\text{g/L}$) by the Dilution Factor (DF). Calculate the adjusted MDL or adjusted CRQL for soil/sediment samples as follows:

$$\text{Adjusted Concentration } \left(\frac{mg}{kg} \right) = C \times \frac{W_M}{W \times S} \times DF$$

Where,

- C = MDL or CRQL (mg/kg)
 W_M = Minimum method required aliquot amount (g) (0.50 g)
W = Initial aliquot amount (g)
S = % Solids/100 (see Exhibit D of ISM01.2 - Introduction to Analytical Methods, Section 1.6).
DF = Dilution Factor

Calculations for Cyanide

Aqueous/Water Sample Concentration:

$$CN \text{ Concentration } \left(\frac{\mu g}{L} \right) = C \times \frac{V_f}{V} \times DF$$

Where,

- C = Instrument value in $\mu\text{g/L}$ CN from the calibration curve
V_f = Final prepared (absorbing solution) volume (mL)
V = Initial aliquot amount (mL)
DF = Dilution Factor

Soil/Sediment Sample Concentration:

$$CN \text{ Concentration } \left(\frac{mg}{kg} \right) = C \times \frac{V_f}{W \times S} \times \frac{DF}{1000}$$

Where,

- C = Instrument value in $\mu\text{g/L}$ CN from the calibration curve
V_f = Final prepared (absorbing solution) volume (mL)
W = Initial aliquot amount (g)
S = % Solids/100 (see Exhibit D of ISM01.2 - Introduction to Analytical Methods, Section 1.6)
DF = Dilution Factor

Adjusted Method Detection Limit (MDL)/Adjusted Contract Required Quantitation Limit (CRQL) Calculation:

To calculate the adjusted MDL or adjusted CRQL for aqueous/water samples, follow the instructions in Exhibit D of ISM01.2 – Data Analysis and Calculations, Section 11.1.1. Calculate the adjusted MDL or adjusted CRQL for soil/sediment samples as follows:

$$Adjusted \text{ Concentration } \left(\frac{mg}{kg} \right) = C \times \frac{W_M}{W \times S} \times DF$$

Where,

- C = MDL or CRQL (mg/kg)
- W_M = Minimum method required aliquot amount (g) (1.00 g for Midi or 0.50 g for Micro)
- W = Initial aliquot amount (g)
- S = % Solids/100 (see Exhibit D of ISM01.2 - Introduction to Analytical Methods, Section 1.6)
- DF = Dilution Factor

APPENDIX A: GLOSSARY

Analyte -- The element of interest, ion, or parameter an analysis seeks to determine.

Analytical Services Branch (ASB) -- Directs the Contract Laboratory Program (CLP) from within the Office of Superfund Remediation and Technical Innovation (OSRTI) in the Office of Solid Waste and Emergency Response (OSWER).

Analytical Sample -- Any solution or media introduced into an instrument on which an analysis is performed excluding instrument calibration, Initial Calibration Verification (ICV), Initial Calibration Blank (ICB), Continuing Calibration Verification (CCV), and Continuing Calibration Blank (CCB). Note that the following are all defined as analytical samples: undiluted and diluted samples (USEPA and non-USEPA); Matrix Spike samples; duplicate samples; serial dilution samples, analytical (post-digestion/post-distillation) spike samples; Interference Check Samples (ICSs); Laboratory Control Samples (LCSs); and Preparation Blanks.

Associated Samples -- Any sample related to a particular Quality Control (QC) analysis. For example, for Initial Calibration Verification (ICV), all samples run under the same calibration curve. For duplicates, all Sample Delivery Group (SDG) samples digested/distilled of the same matrix.

Blank -- A sample designed to assess specific sources of contamination. See individual definitions for types of blanks.

Calibration -- The establishment of an analytical curve based on the absorbance, emission intensity, or other measured characteristic of known standards. The calibration standards are to be prepared using the same type of reagents or concentration of acids as used in the sample preparation.

Calibration Blank -- A blank solution containing all of the reagents in the same concentration as those used in the analytical sample preparation. This blank is not subject to the preparation method.

Calibration Curve -- A plot of instrument response versus concentration of standards.

Calibration Standards -- A series of known standard solutions used by the analyst for calibration of the instrument (i.e., preparation of the analytical curve). The solutions may or may not be subjected to the preparation method, but contain the same matrix (i.e., the same amount of reagents and/or preservatives) as the sample preparations to be analyzed.

Case -- A finite, usually predetermined number of samples collected over a given time period from a particular site. Case numbers are assigned by the Sample Management Office (SMO). A Case consists of one or more Sample Delivery Groups (SDGs).

Continuing Calibration Blank (CCB) -- A reagent water sample that is run 2 hours (ICP-AES, ICP-MS) or every hour (Hg, CN) and designed to detect any carryover contamination.

Contract Compliance Screening (CCS) -- A screening of electronic and hardcopy data deliverables for completeness and compliance with the contract. This screening is performed under USEPA direction by the Contract Laboratory Program (CLP) Sample Management Office (SMO) contractor.

Continuing Calibration Verification (CCV) -- A single parameter or multi-parameter standard solution prepared by the analyst and used to verify the stability of the instrument calibration with time, and the instrument performance during the analysis of samples. The CCV can be one of the calibration standards. However, all parameters being measured by the particular system must be

represented in this standard and the standard must have the same matrix (i.e., the same amount of reagents and/or preservatives) as the samples. The CCV should have a concentration in the middle of the calibration range and shall be run every 2 hours (ICP-AES, ICP-MS) or every hour (Hg, CN).

Contract Laboratory Program (CLP) -- Supports the USEPA's Superfund effort by providing a range of state-of-the-art chemical analytical services of known quality. This program is directed by the Analytical Services Branch (ASB) of the Office of Superfund Remediation and Technical Innovation (OSRTI) of USEPA.

Contract Laboratory Program Project Officer (CLP PO) -- The Regional USEPA official responsible for monitoring laboratory performance and/or requesting analytical data or services from a CLP laboratory.

Contract Required Quantitation Limit (CRQL) -- Minimum level of quantitation acceptable under the contract Statement of Work (SOW).

Duplicate -- A second aliquot of a sample that is treated the same as the original sample in order to determine the precision of the method.

Field Blank -- Any sample that is submitted from the field and identified as a blank. A field blank is used to check for cross-contamination during sample collection, sample shipment, and in the laboratory. A field blank includes trip blanks, rinsate blanks, bottle blanks, equipment blanks, preservative blanks, decontamination blanks, etc.

Field Duplicate -- A duplicate sample generated in the field, not in the laboratory.

Holding Time -- The maximum amount of time samples may be held before they are processed.

Contractual -- The maximum amount of time that the Contract Laboratory Program (CLP) laboratory may hold the samples from the sample receipt date until analysis and still be in compliance with the terms of the contract, as specified in the CLP Analytical Services Statement of Work (SOW). These times are the same or less than technical holding times to allow for sample packaging and shipping.

Technical -- The maximum amount of time that samples may be held from the collection date until analysis.

Initial Calibration -- Analysis of analytical standards for a series of different specified concentrations to define the quantitative response, linearity, and dynamic range of the instrument to target analytes.

Initial Calibration Blank (ICB) -- The first blank standard run to confirm the calibration curve.

Initial Calibration Verification (ICV) -- Solution(s) prepared from stock standard solutions, metals, or salts obtained from a source separate from that utilized to prepare the calibration standards. The ICV is used to verify the concentration of the calibration standards and the adequacy of the instrument calibration. The ICV should be traceable to National Institute of Standards and Technology (NIST) or other certified standard sources when USEPA ICV solutions are not available.

Internal Standard -- A non-target element added to a sample at a known concentration after preparation but prior to analysis. Instrument responses to internal standards are monitored as a means of assessing overall instrument performance.

Interference Check Sample (ICS) -- Verifies the contract laboratory's ability to overcome interferences typical of those found in samples.

Laboratory Control Sample (LCS) -- A control sample spiked at known level(s). LCSs are processed using the same sample preparation, reagents, and analytical methods employed for the USEPA samples received.

Matrix -- The predominant material of which the sample to be analyzed is composed. For the purposes of this document, the matrices are aqueous/water, soil/sediment, wipe, and filter.

Matrix Spike -- Introduction of a known concentration of analyte into a sample to provide information about the effect of the sample matrix on the digestion and measurement methodology (also identified as a pre-distillation/digestion spike).

Method Detection Limit (MDL) -- The concentration of a target parameter that, when a sample is processed through the complete method, produces a signal with 99 percent probability that it is different from the blank. For 7 replicates of the sample, the mean value must be 3.14s above the blank, where "s" is the standard deviation of the 7 replicates.

Narrative (SDG Narrative) -- Portion of the data package which includes laboratory, contract, Case, Sample Number identification, and descriptive documentation of any problems encountered in processing the samples, along with corrective action taken and problem resolution.

Office of Solid Waste and Emergency Response (OSWER) -- The USEPA office that provides policy, guidance, and direction for the USEPA's solid waste and emergency response programs, including Superfund.

Percent Difference (%D) -- As used in this document and the Statement of Work (SOW), is used to compare two values. The difference between the two values divided by one of the values.

Performance Evaluation (PE) Sample -- A sample of known composition provided by USEPA for contractor analysis. Used by USEPA to evaluate Contractor performance.

Post Digestion Spike -- The addition of a known amount of standard after digestion or distillation (also identified as an analytical spike).

Preparation Blank -- An analytical control that contains reagent water and reagents, which is carried through the entire preparation and analytical procedure.

Relative Percent Difference (RPD) -- As used in this document and the Statement of Work (SOW) to compare two values, the RPD is based on the mean of the two values, and is reported as an absolute value (i.e., always expressed as a positive number or zero).

Regional Sample Control Center Coordinator (RSCC) -- In USEPA Regions, coordinates sampling efforts and serves as the central point-of-contact for sampling questions and problems. Also assists in coordinating the level of Regional sampling activities to correspond with the monthly projected demand for analytical services.

Relative Standard Deviation (RSD) -- As used in this document and the Statement of Work (SOW), the mean divided by the standard deviation, expressed as a percentage.

Sample -- A single, discrete portion of material to be analyzed, which is contained in single or multiple containers and identified by a unique Sample Number.

Sample Delivery Group (SDG) -- A unit within a sample Case that is used to identify a group of samples for delivery. An SDG is defined by the following, whichever is most frequent:

- a. Each 20 field samples [excluding Performance Evaluation (PE) samples] within a Case; or
- b. Each 7 calendar day period (3 calendar day period for 7-day turnaround) during which field samples in a Case are received (said period beginning with the receipt of the first sample in the SDG).

c. Scheduled at the same level of deliverable.

In addition, all samples and/or sample fractions assigned to an SDG must be scheduled under the same contractual turnaround time. Preliminary Results have **no impact** on defining the SDG. Samples may be assigned to SDGs by matrix (i.e., all soil/sediment samples in one SDG, all aqueous/water samples in another) at the discretion of the laboratory.

Sample Management Office (SMO) -- A contractor-operated facility operated under the SMO contract, awarded and administered by the USEPA. Provides necessary management, operations, and administrative support to the Contract Laboratory Program (CLP).

Serial Dilution -- The dilution of a sample by a factor of five. When corrected by the Dilution Factor (DF), the diluted sample must agree with the original undiluted sample within specified limits. Serial dilution may reflect the influence of interferents [Inductively Coupled Plasma (ICP) only].

Statement of Work (SOW) -- A document which specifies how laboratories analyze samples under a particular Contract Laboratory Program (CLP) analytical program.

Tune -- Analysis of a solution containing a range of isotope masses to establish Inductively Coupled Plasma - Mass Spectrometry (ICP-MS) mass-scale accuracy, mass resolution, and precision prior to calibration.

APPENDIX B: INORGANIC DATA EXECUTIVE NARRATIVE TEMPLATE

	UNITED STATES ENVIRONMENTAL PROTECTION AGENCY REGION 2 DESA/HWSS/HWSS 3899, Woodbridge Avenue, Edison, NJ 08837
<u>EXECUTIVE NARRATIVE</u>	
Case No.:	SDG No.:
Site:	Laboratory:

VALIDATION SOP

TOC (Solid/Liquid)

EDS SOP: TOC-01
Rev. 2 07/10

TOTAL ORGANIC CARBON (TOC) METHOD VALIDATION CHECKLIST
Environmental Data Services
Lloyd Kahn (soil) & USEPA 9060 (liquid)

SITE:

DATE:

SDG:

Note: This procedure is appropriate for validation of the following analyses: Total Organic Carbon (TOC), Dissolved Organic Carbon (DOC) and Particulate Organic Carbon (POC)

Y N N/A

Data Completeness and Deliverables

Have any missing deliverables been received and added to the data package? _____

ACTION: Call lab for explanation/resubmittal of any missing deliverables. If the lab cannot provide them, note the effect on review of the data in the non-compliance section of the data assessment narrative.

Validation TOC Data

The data validation criteria outlined below applies to Total Organic Carbon data obtained via method Lloyd Kahn for soil samples and/or USEPA 9060 for liquid samples.

Custody Documents and Narratives

Are chains of custody present and complete for all samples? _____

ACTION: Contact lab for replacement of missing documents.

Do chains of custody or lab narratives indicate any problems with sample receipt, condition of samples, analytical problems or special notations affecting the quality of the data? _____

Y N N/A

Preservation Requirements

Is the cooler temperature for soil and liquid samples received at the laboratory below 4°C ± 2?

Is the liquid sample acidified with H₂SO₄ to a pH of ≤ 2?

ACTION: If samples were not iced or if the ice was melted upon arrival at the laboratory and the temperature of the cooler was elevated (>10°C), or liquid samples not acidified, flag all positive results as estimated “J” and all non-detects “UJ”.

Holding Times

Have any TOC technical holding times, determined from date of collection to date of analyses been exceeded?

NOTE: Liquid and soil samples must be analyzed within 14 days of sample collection.

Table of Holding Time Violations

Sample	Sample Matrix	Date Sampled	Date Lab Received	Date Analyzed
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____
_____	_____	_____	_____	_____

ACTION: If holding times are exceeded, flag all data as estimated (“J” for detects and “UJ” for non-detects). If holding times were grossly exceeded (i.e., more than 2x the holding time), flag all positive data as estimated and reject all non-detects as unusable (“R”).

Y N N/A

Matrix Spike

The following sample was spiked _____

Is a matrix spike/matrix spike duplicate summary present? _____

Were matrix spikes analyzed at the required frequency for each of the following matrixes:

- a. low water? _____
- b. low soil? _____
- c. medium soil? _____

ACTION: If any matrix spike data are missing, call the lab for explanation/re-submittal. If information is not available, document the effect in narrative notes.

Does the matrix spike/matrix spike duplicate for the liquid and soil samples fall within:

$$\begin{aligned} \% \text{ Recovery} &= 50 - 150\% \\ \text{RPD} &= \leq 35\% \end{aligned}$$

How many matrix spike recoveries are outside QC limits? _____

water _____ out of _____

soil _____ out of _____

ACTION: Do not qualify associated sample results on the basis of the MS/MSD data alone. Use the MS/MSD results in conjunction with other QC criteria to determine the need for qualification of associated data. If the MS and MSD both have less than 10 percent recovery for an analyte, reject non-detect results for that analyte and qualify positive results for that analyte as estimated for the sample used for the MS/MSD analysis. If the MS and MSD both have greater than 200 percent recovery for an analyte, reject detected results for that analyte and qualify non-detect results for that analyte as estimated for the sample used for the MS/MSD analysis. Use professional judgment in applying this criterion to other samples.

Y N N/A

Laboratory Control Sample

Were LCS samples evaluated with each batch of 20 samples or less and were observed percent recoveries within the acceptance limits of (50-150%)?

ACTION:

- Contact the lab for an explanation/re-submittal.
- If the % Recovery for the LCS is < 10%, flag all associated sample data "R", for non-detects and "J" for detects.
- If the LCS % Recovery is between 11% - 49%, flag all associated sample data as "J" for both non-detects and detects.
- If the LCS % Recovery is > 150%, flag all associated positive sample data as "J".
- Document in Data Assessment Narrative.

Blanks

Has a method blank analysis been reported per twenty samples of a similar matrix or concentration level, and for each extraction batch?

Are there field/rinse/equipment blanks associated with every sample?

Is the method blank summary present?

Upon examination of laboratory and field blank data, do any blanks contain positive results \geq project quantitation limit (PQL)?

ACTION: If yes, qualify associated results as follows:

If the sample result is greater than the laboratory reporting limit but less than 5 times the blank concentration, flag sample result as non-detect ("U"). If the sample result is reported as detected at a concentration less than the reporting limit and less than 5 times the blank concentration, qualify the sample result as non-detectable at the PQL. For liquid blanks applied to soil/sediment samples, compare the sample result to the equivalent concentration of the blank. The equivalent concentration is determined by assuming that all of the analyte present in the blank aliquot analyzed is present in the sample aliquot analyzed.

The reviewer should note that the blank analyses may not involve the same weights, volumes or dilution factors as the associated samples. These factors must be taken into consideration when applying the 5X criteria such that a comparison of the total contaminants is actually made.

Prepare a list of samples affected.

Y N N/A

Calibration

Are raw data and summary sheets present for both initial and continuing calibrations?

Check calibration factors and % RSD values back to raw data for 10% of data received. Are miscalculations or transcription errors found?

NOTE: If yes, contact the laboratory.

Are the % RSD values for the 5 level initial calibration less than or equal to 20% or correlation coefficient greater than 0.995?

ACTION: Associated sample data for those analytes with % RSD > 20 will be qualified as estimated.

Were initial and continuing calibration verifications evaluated (one for every ten samples)?

Are the % D values between the true and measured concentration values for the continuing calibrations ± 20 ?

ACTION: If no, data following the last in-control standard to the next-in-control standard are potentially affected. Associated detected sample data will be qualified as estimated and associated non-detected sample data will be qualified as estimated if low bias is determined to be present.

Compound Quantitation and Reported Detection Limits

Check data for one or more detected target analytes per sample delivery group. Recalculate from the raw data to check for calculation and transcription errors.

Were miscalculation/transcription errors found?

Are the PQL's adjusted to reflect sample dilutions and percent moisture for solid samples?

ACTION: If errors are found 100% of the data will be evaluated. Contact the lab for the explanation/resubmittals.

Field Duplicates

Were field duplicates submitted for TOC analysis?

ACTION: Where both the sample duplicate values are greater than 5 times the PQL, acceptable sampling and analytical precision is indicated by an RPD for the two field duplicate results of less than or equal to 20 percent for liquid samples and 50 percent for soil samples. Where one or both analytes of the field duplicate pair are less than 5 times the PQL, satisfactory precision is indicated if the field duplicate results agree within 2 times the PQL. If the above criteria are not met for an analyte, qualify all associated sample data for that analyte as estimated ("J").

Data Validation Qualifiers

Qualifier	Description
J	Estimated value (bias undetermined) – The analyte was positively identified; but the associated numerical value is the approximate concentration of the analyte in the sample.
JH	Estimated value (potential high bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential high bias, of the analyte in the sample.
JL	Estimated value (potential low bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential low bias, of the analyte in the sample.
UJ	Estimated non-detect - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
UJL	Estimated non-detect (potential low bias) – The analyte was not detected and the report sample quantitation limit is biased low.
UJH	Estimated non-detect (potential high bias) – The analyte was not detected and the reported sample quantitation limit is biased high.
M	The analytical result reported was obtained from a sediment sample found to contain between 50 and 90 percent moisture and had no other data qualifiers added during the data validating process.
NJ	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.
NJH	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration with a potential high bias, of the analyte concentration.
EMPC	Estimated Maximum Possible Concentration (EMPC).
R	The sample results are rejected. Due to a significant QA/QC problem, the analysis is invalid and provides no information as to whether the analyte is present or not.

Y N N/A

Data Completeness and Deliverables

Have any missing deliverables been received and added to the data package? _____

ACTION: Call lab for explanation/resubmittal of any missing deliverables. If the lab cannot provide them, note the effect on review of the data in the non-compliance section of the data assessment narrative.

Custody Documents and Narratives

Are chains of custody present and complete for all samples? _____

ACTION: Contact lab for replacement of missing documents.

Do chains of custody or lab narratives indicate any problems with sample receipt, condition of samples, analytical problems or special notations affecting the quality of the data? _____

ACTION: If any sample analyzed as a soil other than a TCLP, contains 50-90% water, flag all data as estimated. If the soil sample, other than TCLP, contains more than 90% water, all data would be flagged as unusable.

ACTION: If samples were not iced upon receipt, flag all positive results as estimated, and all non-detects "UJ".

Holding Times

Have any TEPH technical holding times, determined from date of collection to date of extraction been exceeded? _____

NOTE: Water and Soil sample must be extracted within 7 days of sample collection. Extracts must be analyzed within forty days of extraction.

Y N N/A

Table of Holding Time Violations

Sample	Sample Matrix	Date Sampled	Date Lab Received	Date Analyzed	Date Extracted
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____

ACTION: If holding times are exceeded, flag all data as estimated (“J” for detects and “UJ” for non-detects). If holding times were grossly exceeded (i.e., more than 2x the holding time), flag all positive data as estimated and reject all non-detects as unusable (“R”).

Surrogate Recovery

Are surrogate recoveries summarized within the report?

ACTION: If no, contact the lab for explanation/re-submittals. If re-deliverables are not available, document in the narrative notes. (Surrogate % R limits 60-120%).

Were outliers marked as such?

ACTION: Circle outliers in red.

Were surrogate recoveries outside of specifications for any sample or method blank?

ACTION: If any surrogate recoveries are >10% but do not meet project requirements.

1. Flag all positive results as estimated.
2. Flag all non-detects as estimated detection limits when recoveries are less than the lower limit.
3. If recoveries are above the upper limit, do not flag non-detects.
4. If any surrogate recovery is less than 10%:
 - a. qualify positive results as estimated.
 - b. non-detects for that sample should be qualified as unusable.

Professional judgment is used to qualify data that have method blank surrogate recoveries outside acceptance limits in both the original and re-analysis.

Y N N/A

Are surrogate standard retention times within the retention time windows established during the initial calibration?

ACTION: If the retention time limits are not met, the analysis may be qualified unusable (R) for the affected sample on the basis of professional judgement.

Are there any transcription/calculation errors between the surrogate recoveries listed and raw data?

Matrix Spike

Is a matrix spike/matrix spike duplicate summary present?

Were matrix spikes analyzed at the required frequency for each of the following matrixes:

a. low water?

b. low soil?

c. medium soil?

ACTION: If any matrix spike data are missing, call the lab for explanation/re-submittal. If information is not available, document the effect in narrative notes.

$$\begin{aligned} \% \text{ Recovery} &= 70 - 130 \\ \text{RPD} &= 50\% \end{aligned}$$

How many matrix spike recoveries are outside QC limits?

water _____ out of _____

soil _____ out of _____

ACTION: Do not qualify associated sample results on the basis of the MS/MSD data alone. Use the MS/MSD results in conjunction with other QC criteria to determine the need for qualification of associated data. If the MS and MSD both have less than 10 percent recovery for an analyte, reject non-detect results for that analyte and qualify positive results for that analyte as estimated for the sample used for the MS/MSD analysis. If the MS and MSD both have greater than 200 percent recovery for an analyte, reject detected results for that analyte and qualify non-detect results for that analyte as estimated for the sample used for the MS/MSD analysis. Use professional judgment in applying this criterion to other samples.

Y N N/A

Laboratory Control Sample

Were LCS samples evaluated with each batch of 20 samples or less and were observed percent recoveries within the laboratory defined limits of (70-120%)?

ACTION: Document in Data Assessment Narrative.

Blanks

Has a method blank analysis been reported per twenty samples of a similar matrix or concentration level, and for each extraction batch?

Upon examination of laboratory and field blank data, do any blanks contain positive results?

ACTION: If yes, qualify associated results as follows:

If the sample result is greater than the laboratory reporting limit but less than 5 times the blank concentration, flag sample result as non-detect ("U"). If the sample result is reported as detected at a concentration less than the reporting limit and less than 5 times the blank concentration, qualify the sample result as non-detectable at the laboratory reporting limit. For aqueous blanks applied to soil/sediment samples, compare the sample result to the equivalent concentration of the blank. The equivalent concentration is determined by assuming that all of the analyte present in the blank aliquot analyzed is present in the sample aliquot analyzed.

Prepare a list of sample effected.

Are there field/rinse/equipment blanks associated with every sample?

Calibration

Are raw data and summary sheets present for both initial and continuing calibrations?

Are the % RSD values for the initial calibration less than or equal to 20% or correlation coefficient greater than 0.995?

ACTION: Associated sample data for those analytes with % RSD > 20 will be qualified as estimated.

Y N N/A

Are the % D values between the true and measured concentration values for the continuing calibrations ± 20 ?

ACTION: If no, data following the last in-control standard to the next-in-control standard are potentially affected. Associated detected sample data will be qualified as estimated and associated non-detected sample data will be qualified as estimated if low bias is determined to be present.

Check calibration factors and % RSD values back to raw data for 10% of data received.

Are miss-calculations or transcription errors found?

NOTE: If yes, contact the laboratory.

Compound Quantitation and Reported Detection Limits

Check data for one or more detected target analytes per sample for ten percent of the data packages. Recalculate from the raw data to check for calculation and transcription errors.

Were miscalculation/transcription errors found?

ACTION: If errors are found 100% of the data will be evaluated. Contact the lab for the explanation/resubmittals.

Field Duplicates

Were field duplicates submitted for TEPH analysis?

ACTION: Where both the sample duplicate values are greater than 5 times the SQL, acceptable sampling and analytical precision is indicated by an RPD for the two field duplicate results of less than or equal to 100 percent. Where one or both analytes of the field duplicate pair are less than 5 times the SQL, satisfactory precision is indicated if the field duplicate results agree within 2 times the SQL. If the above criteria are not met for an analyte, qualify all associated sample data for that analyte as estimated ("J").

Data Validation Qualifiers

Qualifier	Description
J	Estimated value (bias undetermined) – The analyte was positively identified; but the associated numerical value is the approximate concentration of the analyte in the sample.
JH	Estimated value (potential high bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential high bias, of the analyte in the sample.
JL	Estimated value (potential low bias) – The analyte was positively identified; but the associated numerical value is the approximate concentration, with a potential low bias, of the analyte in the sample.
UJ	Estimated non-detect - The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
UJL	Estimated non-detect (potential low bias) – The analyte was not detected and the report sample quantitation limit is biased low.
UJH	Estimated non-detect (potential high bias) – The analyte was not detected and the reported sample quantitation limit is biased high.
M	The analytical result reported was obtained from a sediment sample found to contain between 50 and 90 percent moisture and had no other data qualifiers added during the data validating process.
NJ	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.
NJH	The organic analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration with a potential high bias, of the analyte concentration.
EMPC	Estimated Maximum Possible Concentration (EMPC).
R	The sample results are rejected. Due to a significant QA/QC problem, the analysis is invalid and provides no information as to whether the analyte is present or not.

I. PURPOSE AND SCOPE:

This document is the Standard Operating Procedure (SOP) for laboratory data evaluation and validation of Hexavalent Chromium analyzed in accordance with USEPA SW-846 Methods 3060A, 7196A and 7199.

II. AUTHORITY:

This document was prepared and revised under the authority of the Assistant Director of the DRMR-HSSE and the Section Chief, ODQ. This revision, maintenance and use of this document is a work output under the NJDEP Quality Assurance Program Plan. The QA Program Plan was prepared by the NJDEP Office of Quality Assurance and in part by DRMR-HSSE-ODQ, and was approved by the USEPA Region II.

III. REFERENCE:

This document was prepared based on materials contained in the document entitled: USEPA Office of Solid Waste and Emergency Response Update III (July 1998) - "Test Methods for Evaluating Solid Waste", USEPA SW-846.

IV. RESPONSIBILITY:

The Assistant Director of DRMR HSSE is responsible for the final review and approval of this document. The Section Chief of ODQ is responsible for the annual review of this document. The Supervisor of ODQ is responsible for the preparation of any revision to this document as well as maintaining ODQ staff compliance with this document.

V. POLICY:

The actions contained in this document are the policy of DRMR- HSSE-ODQ and are derived based on requirements contained in the referenced USEPA SW-846 Methods 3060A, 7196A and 7199.

VI. PROCEDURE:

(A) Introduction

This document is designed to offer guidance in laboratory data evaluation and validation. In some aspects, it is equivalent to a Standard Operating Procedure (SOP); in other more subjective areas, only general guidance is offered due to the complexities and uniqueness of data relative to specific samples.

Those areas where specific SOPs are possible are primarily areas in which definitive performance requirements are established. These requirements are concerned with specifications that are not sample dependent; they specify performance requirements on matters that should be fully under a laboratory's control. These specific areas include laboratory preparation blanks, calibration standards, calibration check standards, and laboratory control standards. Failure to meet these performance requirements warrants that corrective action is taken by the laboratory.

At times, there may be an urgent need to use data that do not meet all QA/QC requirements. Any decision to utilize data for which non-sample specific criteria have not been met is strictly to facilitate the progress of projects requiring the availability of the data and such decisions should be clearly noted in the data validation report. Use of this data does not constitute acceptance of the data in terms of method compliance nor does it release the laboratory from the obligation to perform as per the analytical method. A laboratory submitting data, which are out of specification, may be required to re-run or resubmit data. The only exception to this is in the area of requirements for individual sample analysis; if the nature of the sample itself limits the attainment of specifications, appropriate allowances must be made. An overriding concern of the DRMR-ODQ is to prevent non-sample specific data validation requirements from adversely affecting overall data validation activities. There is ultimately no justification for noncompliance on requirements for performance relative to such areas as blanks, calibration and performance verification standards. Ideally, data validation activities should only be concerned with subjects requiring professional judgment on individual sample results.

With these concepts in mind, this document is designed to permit structured data review. To this end, the document is arranged in order, with the most objective, straightforward validation elements given first.

It will be the data reviewer's responsibility to notify the assigned NJDEP Technical Coordinator and Case Manager concerning problems and shortcomings in regards to laboratory data via a Data Validation Report and a Target Analyte Summary List. If mandatory actions are required, they should be specifically noted in a Data Validation Report. This report should also be used to note overall deficiencies requiring attention as well as comments on general laboratory performance and any discernible trends in the quality of data.

(B) Data Package Deliverables

Data generated using USEPA SW- 846, Update III Hex aivalent Chromium methods must be delivered to NJDEP in t he regulatory format as defined in the currently active Professional Laboratory Services Contract and the Technical Requirements for Site Remediation N.J.A.C. 7:26E. Data delivered in the "Reduced Regulat ory Format" can only be reviewed against the requirements of this SOP and cannot be validated.

(C) Preliminary Review

In order to use this document effectively, t he reviewer should have a general overview of the data deliverable package at hand. The exact number of samples, their assigned laboratory and field identification numbers, thei r matrix, and concentration level, the identity of any field QC samples (blanks, duplicates, spikes, splits) , sampling dates and t he name of laboratory performing sample analyses are essential informa tion. Background information on the site is helpful but at times, it is very difficult to lo cate. The NJDEP Technica l Coordinator or the Case Manager is the best sources for answers or further direction.

The chain-of-custody record provides sample descriptions and the date and time of sampling. Sampling procedures are addressed by NJ DEP "Field Sampling Procedures Manual" requirements. Any discrepancies found by the reviewer must be noted on the data validation report. The non-conformance summary that is s ubmitted by the laboratory is another source of general information. Notable pr oblems with matrices, insufficient sample size for analysis or reanalysis, sample temperature and preservation and unusual events should be found here.

(D) Data Validation

1. Sample Holding Times

A. Objective

The objective is to ascertain the validity of results, based on the holding time of the sample from time of collection to ti me of analysis. Fr om the standpoint of laboratory performance, the time of analysis is needed to determine compliance with the USEPA SW-846, Hexavalent Chromium methods.

B. Requirements

The following holding time requirements were established by the USEPA SW-846, Hexavalent Chromium methods.

- 1) Non Aqueous Samples for Hexavalent Chromium: thirty (30) days from time of sampling to digestion. In addition, the alkaline digestate has been shown to be stable for up to 168 hours after digestion.
- 2) Aqueous Samples for Hexavalent Chromium: 24 hours from time of sampling to analysis.
- 3) The non-aqueous samples should arrive at four degrees centigrade.

C. Evaluation Procedure

- 1) Actual holding times are established by comparing the sampling dates and times on the chain of custody with the dates and times of analysis found in the laboratory data. Exceeding the holding time for a sample may result in a loss of the Hexavalent Chromium. This occurs through any number of mechanisms, such as deposition on the sample container walls or chemical activity. Therefore, from a usability standpoint, when holding time violations occur, the results that are most severely called into question are those which fall below or close to the detection limit or a cleanup level.
- 2) Sample temperature can be found on the chain of custody.

D. Action

- 1) For nonaqueous samples, if the holding time is greater than thirty days but less than or equal to thirty-two days, then the sample concentration and the nondetects are qualified and flagged the data with a "J" or "UJ" respectively. If the holding time exceeds thirty-two days, then all sample results are rejected "R".
- 2) For aqueous samples, if the holding time is greater than 24 hours but less than or equal to 48 hours, then the sample concentration and the nondetects are qualified and flagged the data with a "J" or "UJ" respectively. If the holding time exceeds 48 hours, then all sample results are rejected "R".
- 3) If sample receiving temperature is greater than 6 degrees centigrade, then qualify all associated samples.

2. Instrument Calibration Curve

A. Objective

The objective in establishing compliance requirements for satisfactory instrument calibration is to ensure that the instrument is capable of producing acceptable quantitative data.

B. Requirements

- 1) The instrument must be calibrated daily (once every 24 hours) or each time the instrument is set up, whichever is more frequent.
- 2) The instrument standardization date and time must be included in the raw data.
- 3) A calibration blank and at least four (4) standards in graduated amounts and in the appropriate range (0.10 to 2.0 mg/L) are recommended in establishing the analytical curve for Method 7196A.
- 4) A calibration blank and at least three (3) standards bracketing the anticipated concentration range of the samples are recommended in establishing the analytical curve for Method 7199.
- 5) The calibration curve must have a correlation coefficient of 0.995 or greater for Method 7196A.
- 6) The calibration curve must have a correlation coefficient of 0.999 or greater for Method 7199.

C. Evaluation Procedure

- 1) By checking the raw data, verify that the instrument was calibrated at the proper frequency.
- 2) Verify that the correct number of standards and calibration blanks was used.
- 3) Verify that the date and time of sample analysis was provided.
- 4) Verify that the correlation coefficient for the calibration curve was greater than or equal to 0.995 for Method 7196A.
- 5) Verify that the correlation coefficient for the calibration curve was greater than or equal to 0.999 for Method 7199.
- 6) Verify that if the correlation coefficient was less than the 0.995/0.999, the laboratory analyzed a new calibration curve.

D. Action

- 1) If there are inconsistent time(s), date(s) or instrument IDs on the raw data sheets and reporting forms, the laboratory must be contacted and all inconsistencies must

be resolved. If the reviewer is unable to resolve any discrepancies with the laboratory, then the reviewer must determine on a case by case basis whether to accept, qualify "J", or reject "R" the data in question.

- 2) If the instrument calibration was not performed or calibrated daily, then all associated data are rejected "R".
- 3) If the correct number of instrument calibration standards was not analyzed then all associated data are qualified "J".
- 5) If the correlation coefficient for the calibration curve was less than 0.995 for Method 7196, then all associated data are rejected "R".
- 6) If the correlation coefficient for the calibration curve was less than 0.999 for Method 7199, then all associated data are rejected "R".

3. Calibration Check Standard (CCS)

A. Objective

The CCS documents satisfactory instrument performance (calibration accuracy) during each analysis run.

B. Requirements

- 1) The CCS analyses must be performed at a minimum frequency of once every 10 samples during an analysis run. The CCS should be analyzed at the beginning of the run and after the last analytical sample. For Method 7199, the calibration curve must be verified by analyzing a Quality Control Sample (QCS).
- 2) The CCS should be at or near the mid range level of the calibration curve.
- 3) The same concentration for the CCS must be used throughout the sample analyses.
- 4) The CCS and the QCS results must fall within the control limits of 90-110% of the established value.
- 5) The CCS must be an independently prepared standard from a different source than that used for the initial calibration.

C. Evaluation Procedure

- 1) Review the supporting raw data to verify that the CCS/QCS was performed at the proper frequency.
- 2) Verify that the CCS/QCS was independently prepared and the standard used was at or near the mid range level of the curve.
- 3) Verify that the same CCS concentration was used throughout the analyses.
- 4) Verify that the standard used for performing the CCS/QCS met the acceptance criteria for 90-110%.

D. Action

- 1) If there are inconsistent time(s), date(s) or instrument IDs on the raw data sheets and reporting forms, the laboratory must be contacted and all inconsistencies must be resolved. If the reviewer is unable to resolve any discrepancies with the laboratory, then the reviewer must determine on a case by case basis whether to accept, qualify, or reject the data questioned.
- 2) If the CCS/QCS analysis was not performed, then all associated sample data are rejected "R".
- 3) If the CCS analysis was not performed at the correct frequency, then all associated sample data are qualified "J".
- 4) If the CCS was not at or near the mid range level of the curve, then all associated sample data are qualified "J".
- 5) If the CCS concentration was not the same throughout the analysis, then qualify "J" all associated sample data if the concentration was within the calibration range and reject "R" all associated sample data if the concentration was not within the calibration range.
- 6) If the CCS/QCS analysis was performed but did not meet the percent recovery requirements, use the following guidelines:
 - a) If the CCS/QCS falls outside the acceptance windows but within the ranges of 80-89% or 111-120%, flag the positive hit data of associated samples as estimated (J). In the data validation report, give an indication to the data end user as to the bias of the results (i.e., if the CCS for an analyte is 115%, then it could be stated that the reported results for that analyte should be biased high.)

- b) If an analyte is not detected in a sample and the associated CCS/QCS result is greater than 110% but less than or equal to 120%, then the analytical sample determination is acceptable.
 - c) If the analyte is not detected in a sample and the associated CCS/QCS result is less than 90% but greater than or equal to 80%, then the detection limit may be biased low. In the data validation report, note that the detection limit for that sample may be elevated and flag the data for these samples as estimated (UJ).
 - d) If the CCS/QCS result is less than 80% or greater than 120%, this is indicative of severe analytical deficiencies and the data are rejected as unusable (R).
- 7) For a given CCS, the actions described in item 6) will affect the samples that are analyzed between the two acceptable CCSs that bracket the unacceptable CCS.

4. Calibration Blanks

A. Objective

Calibration Blanks are analyzed in order to establish that the instrument has no contamination or drifting problems, and to ensure that the instrument is capable of producing acceptable quantitative data.

B. Requirements

- 1) A Calibration Blank must be used in establishing the analytical curve.
- 2) The absolute value of the calibration blank should not exceed the Method Detection Limit (MDL).
- 3) A Calibration Blank must be analyzed before the initial instrument's calibration standards and after each CCS.

C. Evaluation Procedure

- 1) Review the supporting raw data to verify that the Calibration Blank analysis was performed and at the proper sequence.
- 2) Verify that the Calibration Blank absolute value was less than the MDL.

D. Action

- 1) If there are inconsistent time(s), date(s) or instrument IDs on reporting forms and raw data sheets, the laboratory must be contacted and all inconsistencies resolved. If the reviewer is unable to resolve any discrepancies with the laboratory, then the reviewer must determine on a case by case basis whether to accept, qualify "J", or reject "R" the data in question.
- 2) If the absolute value of the Calibration Blank exceeds the MDL, then highly qualify "J" the data in all associated analytical samples.
- 3) If no Calibration Blank was analyzed before the initial instrument's calibration standards was run, then all associated sample data are rejected "R".

5. Preparation/Reagent Blanks and Field Blanks

A. Objective

The assessment of results regarding blank analyses is for determining the existence and magnitude of contamination problems. The criteria for the evaluation of blanks apply to all blanks, including, but not limited to preparation/reagent blanks and field blanks. The responsibility for action in the case of unsuitable blank results depends upon the circumstances and the origin of the blank. If problems with any blank exist, all associated data must be carefully evaluated to determine whether there is an inherent variability in the data set or the problem is an isolated occurrence not affecting other data.

B. Requirements

- 1) The laboratory preparation/ reagent blank is an in-house blank the laboratory is responsible for reporting.
- 2) At least one preparation/reagent blank, consisting of deionized distilled water, processed through each sample preparation and analysis procedure must be prepared and analyzed with every Sample Delivery Group (SDG), or for each batch of samples digested, whichever is more frequent. (Exception: If only soil samples were analyzed, an aqueous preparation blank is not required for the associated field blank.)
- 3) The preparation/reagent blank concentration must be less than the method detection limit or one-tenth the regulatory limit or action level, whichever is greater or the entire batch must be redigested.

- 4) The minimum field blank requirement is as follows. There should be at least one field blank/matrix/per sampling date.
- 5) It should be noted that inorganic analysis for trip blanks is not required unless specifically requested by NJDEP on a site by site basis.

C. Evaluation Procedure

- 1) Review the results for the preparation/reagent blank(s) (raw data, strip charts, printer tapes, bench sheets, et c.) in order to verify that results were accurately reported.
- 2) Verify that the proper number of preparation/reagent blanks was analyzed.
- 3) Verify that the proper number of field blanks was analyzed, as per the request of the data end user.
- 4) Verify that the sample concentration is not corrected for any preparation/reagent blank, trip blank or field blank values.
- 5) Verify that the preparation/reagent blank concentration was less than the method detection limit or one-tenth the regulatory limit or action level, whichever is greater.

D. Action

- 1) If there are inconsistent time(s), date(s) or instrument IDs on reporting forms and raw data sheets, the laboratory must be contacted and all inconsistencies must be resolved. If the reviewer is unable to resolve any discrepancies with the laboratory, then the reviewer must determine on a case by case basis whether to accept, qualify "J", or reject "R" the data.
- 2) If any samples are not associated with a preparation/reagent blank, all data from the affected samples are rejected "R". (An aqueous reagent blank for the field blank is not required if only soil samples were analyzed).
- 3) If no field blanks were requested for analyses or if the incorrect number was collected and analyzed, note it in the data validation report.
- 4) If the preparation/reagent blank or field blank results were subtracted from associated sample results, add the applicable blank results to the sample results before proceeding to steps 6) and 7) below. The laboratory must be notified of the data reporting error and a revised data report package must be submitted.

- 5) If the sample concentration of Hexavalent Chromium is greater than ten (10) times the preparation/reagent blank and the blank was less than the MDL or one-tenth the regulatory limit, then no qualifications are necessary. If the preparation/reagent blank was greater than the MDL or one-tenth the regulatory limit and the samples were not redigested, then all associated sample results are rejected "R".
- 6) When the sample concentration of Hexavalent Chromium is less than or equal to ten (10) times the preparation/reagent blank, then the following actions are to be taken.
 - a) If the concentration of Hexavalent Chromium in a sample is less than or equal to three (3) times the concentration of Hexavalent Chromium in the associated preparation/reagent blank, the presence of Hexavalent Chromium in the sample is negated due to laboratory contamination, as indicated by the preparation/reagent blank. The "B" qualifier must be reported with the analytical result.
 - b) If the concentration of Hexavalent Chromium in a sample is greater than three (3) times the concentration of Hexavalent Chromium in the associated preparation/reagent blank, the presence of Hexavalent Chromium in the sample is considered "real". The "B" qualifier must be reported with the analytical result. The concentration must also be reported with the "J" qualifier and is quantitatively qualified due to preparation/reagent blank contamination.
 - c) If the value of Hexavalent Chromium in the preparation/reagent blank is negative, then all positive values found in a field sample will be quantitatively qualified because of the possibility of a negative drift in the instrument and may be biased low.
 - d) If the value of Hexavalent Chromium in the preparation/reagent blank is negative, then all non-detected values found in a field sample are reported "UJ" because of the possibility of a negative drift in the instrument and may give rise to a false negative (ND).
- 7) When the sample concentration of Hexavalent Chromium is less than or equal to ten (10) times the field blank concentration, then the following actions are to be taken.
 - a) If the concentration of Hexavalent Chromium in a sample is less than or equal to three (3) times the concentration of Hexavalent Chromium in the associated field blank, then the presence of Hexavalent Chromium in the

sample is negated due to introduced contamination, as indicated by the field blank.

- b) If the concentration of Hexavalent Chromium in a sample is greater than three (3) times the concentration of Hexavalent Chromium in the associated field blank, then the presence of Hexavalent Chromium in the sample is considered "real". The concentration must be reported with the "J" qualifier and is quantitatively qualified due to field blank contamination.

6. Predigestion Spike Sample Analyses (non aqueous samples only)

A. Objective

The soluble and insoluble spiked samples analyses are designed to provide information about the effect of the sample matrix on the digestion and measurement methodology. The insoluble spike is used to evaluate the dissolution during the digestion process.

B. Requirements

- 1) At least two spiked sample (soluble and insoluble) analyses must be performed on each group of samples of a similar matrix type (e.g., sediment and soil) and concentration (e.g., low and medium) for each digestion batch of samples or for each 20 samples received, whichever is more frequent.
- 2) If the spike analyses are performed on the same sample that was also chosen for the duplicate sample analysis, spike calculations must be performed using the results of the original sample analysis.
- 3) The analyte spikes must be added before sample digestion and the spike recovery must be within the control limits of 75-125%.
- 4) The soluble spike concentration should be at 40 mg Cr(VI)/Kg or at twice the sample concentration whichever is greater.
- 5) The insoluble spike concentration should be around 400 to 800 mg Cr(VI)/Kg.

C. Evaluation Procedure

- 1) Verify that the proper number of spikes and the proper spike concentrations were used.
- 2) If the spike analyses are performed on the same sample that was chosen for

duplicate analysis, verify that the laboratory used the original sample results for calculations.

- 3) Spot check the raw data to verify that results were correctly calculated and reported on the spike analysis form. Predigestion spike percent recoveries (% R) are calculated as follows:

$$\% \text{ Recovery} = \frac{\text{SSR} - \text{SR}}{\text{SA}} \times 100$$

Where: SSR = Spike sample results
SR = Sample results
SA = Spike added

- 4) Verify that the spike recoveries fall within the control limits of 75-125%.
- 5) Verify that if spike recoveries fell outside the control limits of 75-125% that the entire batch was rehomogenized/redigested/reanalyzed.
- 6) Verify that a field sample and not a field blank was used for predigestion spike analyses as per method requirements.

D. Action

- 1) If there are inconsistent time(s), date(s) or instrument IDs on reporting forms and raw data sheets, the laboratory must be contacted and all inconsistencies resolved. If the reviewer is unable to resolve any discrepancies with the laboratory, then the reviewer must determine on a case by case basis whether to accept, qualify "J", or reject "R" the data in question.
- 2) If no spike analyses were performed for non-aqueous samples (i.e., either soil and/or sediment samples) or if a field blank was used, then all associated sample data are rejected "R".
- 3) If the frequency of the spike analysis exceeded 1 in 20 samples but was within 1 in 25, qualify "J" the data from samples 21-25.
- 4) If the frequency of a spike analysis exceeded 1 in 25 samples, reject "R" all sample data that follow the 25th sample.
- 5) If either spike recovery was outside the QC limit and the laboratory failed to rehomogenize/redigest/reanalyze, then all associated sample data are rejected "R".
- 6) If the wrong spike concentration was used, then qualify "J" hexavalent chromium in

all associated sample data.

- 7) If the reported sample concentration for hexavalent chromium is greater than four times the concentration of the spike, no further action needs to be taken and the sample data are acceptable for use.
- 8) The following guidelines are recommended for use in evaluating data usability when the spike recoveries do not fall within control limits and the reported sample concentration is less than four times the concentration of the spike.
 - a) If the spike recovery is $> 125\%$ and the reported sample results are less than the MDL, this data are acceptable for use.
 - b) If the spike recovery is $> 125\%$ but $< 150\%$ and the reported sample levels are greater than the MDL, flag the data as estimated "J" and indicate in the data validation report as to the potential high bias in the results.
 - c) If the spike recovery is $\geq 50\%$ but $< 75\%$ and the reported sample levels are greater than the MDL, flag the data as estimated "J" and indicate in the data validation report as to the potential low bias of the results.
 - d) If an analyte is not detected and the spike recovery is $\geq 50\%$ but $< 75\%$, the detection limit may be biased low. In the data validation report, note that the detection limit reported by the laboratory for that sample may be biased low. Flag the data for these samples as estimated "UJ".
 - e) For sample spike recovery results that fall $< 50\%$, the data should be reported as unusable "R". This is indicative of severe analytical deficiency and the reviewer should state it in the narrative.
 - f) If the spike recovery is $> 150\%$, and the reported sample results $> MDL$, the data should be reported as unusable "R". This is indicative of severe analytical deficiency and the reviewer should state it in the narrative.
 - g) The laboratory should be contacted and they should consider redigesting the spike sample with a higher matrix spike level.

7. Post-Digestion Spike Sample (PDS)

A. Objective

The PDS analysis is designed to verify that neither a reducing condition nor a chemical interference is affecting the analysis.

B. Requirements

- 1) At least one PDS analysis must be performed on each group of samples of a similar matrix type (e.g., water and soil) for each batch of samples or for each 20 samples received, whichever is more frequent.
- 2) As per method requirements, samples identified as field or preparation/reagent blanks cannot be used for PDS analysis.
- 3) If the PDS analysis is performed on the same sample that was also chosen for the duplicate sample analysis, PDS spike recovery calculations must be performed using the result of the original sample analysis.
- 4) The aqueous sample chosen for PDS should be spiked at twice the sample concentration or at 30ug/L whichever is greater.
- 5) The soil sample chosen for PDS should be spiked at 40 mg/Kg or twice the sample concentration, whichever is greater.
- 6) The PDS spike recovery must be within the control limits of 85-115%.
- 7) If the PDS recovery is less than 85% for method 7196A, then reanalyze the PDS to determine if the low spike recovery is due to a reducing agent.
- 8) When the sample concentration is less than the MDL, use 0 for the sample results only for calculating the % recovery.

C. Evaluation Procedure

- 1) Verify that the PDS analysis was performed at the proper frequency (1 for every 20 samples) and that the proper PDS concentration was used.
- 2) Verify that a field sample and not a field blank or preparation/ reagent blank was used for PDS analysis as per method requirements.
- 3) Spot-check the raw data to verify that PDS recovery result was correctly calculated and reported. PDS percent recoveries (% R) are calculated as follows:

$$\% \text{ Recovery} = \frac{\text{SSR} - \text{SR}}{\text{SA}} \times 100$$

Where: SSR = PDS sample result
 SR = Sample result
 SA = Spike added

- 4) Verify that the PDS recovery results fall within the specified limits of 85-115%.
- 5) Verify that the PDS was reanalyzed if the recovery was less than 85% for method 7196A.
- 6) Verify that when the addition of a PDS to a sample extends the concentration beyond the calibration range, a dilution was performed.

D. Action

- 1) If there are inconsistent time(s), date(s) or instrument IDs on reporting forms or raw data sheets, the laboratory must be contacted and all inconsistencies resolved. If the reviewer is unable to resolve any of the discrepancies, then the reviewer must determine on a case by case basis whether to accept, qualify "J", or reject "R" the data in question.
- 2) If no PDS analysis was performed for either soil and/or aqueous samples, all associated sample data are rejected "R".
- 3) If a field blank or preparation/ reagent blank was used for PDS analysis, then reject "R" all associated sample data.
- 5) If the frequency of the PDS analysis exceeded 1 in 20 samples but was within 1 in 25 qualify "J" the data from samples 21-25.
- 5) If the frequency of a PDS analysis exceeded 1 in 25 samples, reject "R" all sample data that follow the 25th sample.
- 6) If the wrong PDS concentration was used, qualify "J", Hexavalent Chromium in all associated sample data.
- 7) The following guidelines are recommended for use in evaluating data usability when the PDS recoveries do not fall within 85-115% limits:
 - a) If the PDS recovery is > 115% and the reported sample results are less than the MDL, the data are acceptable for use.
 - b) If the PDS recovery is > 115% and the reported sample concentrations are greater than the MDL, then flag data as estimated "J" and give an indication in the data validation report as to the potential high bias in the results.
 - c) If the PDS recovery is less than 85%, the following actions are taken:

- i) If no reanalysis was performed, and the reported sample levels are greater than the IDL, then the data are qualified "J". In the data validation report, give an indication as to the low bias of the results.
 - ii) If no reanalysis was performed, and the reported sample levels are less than the IDL then the detection limit is qualified "UJ". In the data validation report, note that the detection limit reported by the laboratory for that sample may be biased low.
 - iii) If the laboratory reanalyzes the aliquot and the recovery is within 85-115% recovery limits, no action is needed.
 - iv) If the reanalysis is still outside the (recovery) limits, then qualify "J" all associated samples.
- 8) If the laboratory failed to make a dilution to any PDS that exceeded the calibration range, qualify "J" all associated samples.

8. Duplicate Sample Analysis

A. Objective

The duplicate sample analysis is used to evaluate the precision of the method for Hexavalent Chromium. The data reviewer can use the results of the duplicate analysis as an indicator of the precision of the sample results.

B. Requirements

- 1) One duplicate sample must be analyzed from each group of samples of a similar matrix type (i.e., water, and soil) and for each batch of samples or for each 20 samples received, whichever is more frequent.
- 2) As per method requirements, samples identified as field blanks or preparation/reagent blanks cannot be used for duplicate sample analysis.
- 3) Duplicate results must be reported on duplicate form in ug/L for aqueous samples and mg/Kg dry weight basis for solid samples.
- 4) A control limit of ≤ 20 % Relative Percent Different (RPD) shall be used if both the original and the duplicate results are greater than or equal to four times the laboratory reporting limit.

The RPD for Hexavalent Chromium is calculated as follows:

$$RPD = \frac{S - D}{(S + D)/2} \times 100$$

Where: RPD = Relative Percent Difference
S = First sample value (original)
D = Second sample value (duplicate)

- 5) A control limit of \pm the reporting limit shall be used when either the original or the duplicate sample is less than four times the laboratory reporting limit.

C. Evaluation Procedure

- 1) Verify that duplicate samples were analyzed for each matrix type and at the proper frequency.
- 2) Spot-check the raw data to verify that the results have been correctly reported on the duplicate form.
- 3) Verify that a field sample was used for duplicate analysis as per method requirements.
- 4) Verify that the correct control limits were used.

D. Action

- 1) If there are inconsistent time(s), date(s), or instrument IDs on reporting forms and raw data sheets, the laboratory must be contacted and all inconsistencies resolved. If the reviewer is unable to resolve any discrepancies with the laboratory, then the reviewer must determine on a case by case basis whether to accept, qualify "J", or reject "R" the data in question.
- 2) If no duplicate sample was analyzed for either soil and/or aqueous matrices, then all associated sample data are rejected "R".
- 3) If a field blank or preparation/reagent blank was used for duplicate analysis, then all associated sample data are rejected "R".
- 4) If the frequency of the duplicate analysis exceeded 1 in 20 samples but was within 1 in 25, qualify "J" the data from samples 21-25.
- 5) If the frequency of a duplicate analysis exceeded 1 in 25 samples, reject "R" all sample data that follow the 25th sample.
- 6) If the duplicate sample analyses results for Hexavalent Chromium fall outside the

control windows of 20% RPD or \pm the reporting limit, whichever is appropriate, the results in all associated samples of the same matrix type should be flagged as estimated "J".

9. Laboratory Control Sample Analysis (non aqueous samples only)

A. Objective

The laboratory control sample analysis (LCS) is designed to serve as a monitor of the efficiency of the digestion procedure. The inability of the laboratory to successfully analyze a known LCS is indicative of an analytical problem related to digestion/sample preparation procedures and/or instrument operations.

B. Requirements

- 1) One LCS must be analyzed for every SDG of non-aqueous samples received or for each batch of samples digested whichever is more frequent. Results for each Hexavalent Chromium should be reported on the LCS form.
- 2) The LCS must be prepared by the laboratory.
- 3) The LCS percent recovery (%R) control limit is 80% -120%.

C. Evaluation

- 1) Verify that the LCS was analyzed and at the proper frequency.
- 2) Review the LCS form and verify that the results fall within the specified control limits.
- 3) Spot check the raw data (printouts, strip chart, and bench sheets) to verify the reported recoveries on the LCS form.
- 4) Verify that if the LCS recovery fell outside the control limits of 80% -120% that the LCS was reanalyzed.

D. Action

- 1) If there are inconsistent time(s), date(s) or instrument IDs on reporting forms and raw data sheets, the laboratory must be contacted and all inconsistencies resolved. If the reviewer is unable to resolve any discrepancies with the laboratory, then the reviewer must determine on a case by case basis whether to accept, qualify "J", or reject "R" the data.

- 2) If the frequency of a LCS analysis exceeded 1 in 20 samples, qualify "J" the data from the 21st sample on.
- 3) If the LCS was not within control limit and the laboratory failed to reanalyze the LCS, then reject "R" all associated samples.
- 4) If the LCS was not within control limit, and the laboratory reanalyzed and the LCS is still outside the control limit then qualify "J" all associated samples.

10. Sample Result Verification

A. Objective

The sample results verification process checks the correctness of the data acquisition, computation, transcription and the validity of the calibration curve construction.

B. Requirements

- 1) It is implicit within the USEPA SW-846 Final Update III document that all required data reduction, reporting and documentation be performed and presented in such a manner so as to ensure the data package is both complete as well as free of computational and/or transcription errors.
- 2) Percent solids determinations are required for all non-aqueous samples. Sample dry weight corrections are made using the percent solids results.
- 3) USEPA SW-846 methods 3060A, 7196A & 7199 require pH adjustments for each sample and their final readings recorded in a laboratory notebook.
 - a) Method 3060A-pHs of all analytical solutions for non-aqueous samples analyzed by Method 7196A must be adjusted within a range of 7.0 - 8.0.
 - b) Method 3060A-pHs of all analytical solutions for non-aqueous samples analyzed by Method 7199 must be adjusted within a range of 9.0 - 9.5.
 - c) Method 7196A - pHs of all analytical solutions must be adjusted within a range of 1.5 - 2.5.
- 4) USEPA SW-846 Method 3060A requires that the digestion solution temperature range of 90 - 95 degrees centigrade must be maintained for at least 60 minutes. The laboratory should monitor and record the temperature in the laboratory notebook for one sample.
- 5) For Method 7199, each sample should be injected twice and the relative standard

deviation of the duplicates should be $\leq 20\%$ RPD.

C. Evaluation Procedure

- 1) Examine the raw data for any anomalies (i.e., negative absorbance, omissions, etc.).
- 2) Verify that there were no computational errors in sample concentration by recalculating the results for Hexavalent Chromium in a percentage of samples.
- 3) Calculations

- a) For aqueous samples, calculate the Hexavalent Chromium results as follows:

$$\text{Hexavalent Chromium in mg/L} = A \times E$$

Where: A = concentration from the calibration curve in mg/L.
E = Dilution (if necessary)

- b) For solid samples, when concentrations are reported as mg/Kg on a dry basis use the following formula.

$$\text{mg Hexavalent Chromium/Kg sample} = \frac{A \times B \times E}{C \times D}$$

Where: A = concentration from the calibration curve in mg/L.
B = Final digested volume in liters.
C = Wet weight of sample in kilograms.
D = % Solids/100
E = Dilution (if necessary)

- 4) Verify that there were no transcription errors by checking the raw data versus the analytical result summary sheet.
- 5)
 - a) Verify that percent solids analysis for all non-aqueous samples was performed.
 - b) Verify the percent solids determinations by spot checking the laboratory results using the following formula.

$$\% \text{ Solids} = \frac{\text{Sample dry weight}}{\text{Sample wet weight}} \times 100$$

- 6) Verify that the laboratory has provided pH readings for Methods 3060A, 7196A and/or 7199.
- 7) Verify that the pH reading(s) were within the specified range(s) for each sample.
- 6) Verify that the sample digestion solution temperature readings were provided, and were within a temperature range of 90 – 95 degrees centigrade.
- 9) Verify that for Method 7199, each sample was injected twice and the relative standard deviation of the duplicates was $\leq 20\%$ RPD.

D. Action

- 1) If any raw data anomalies were found, the reviewer should use judgement on how the sample data would be affected.
- 2) If differences are identified between the laboratory reported result and the reviewer calculated result, the following actions should be taken:
 - a) If the laboratory reported result is within 10% of the reviewer calculated result and the difference could be attributed to rounding, no corrective action is required.
 - b) If the laboratory reported result differs by 10% from the reviewer calculated result, but not attributable to rounding, try to determine the source(s) of error. If this cannot be determined, the laboratory should be contacted about the sample result discrepancy. If an error is confirmed, request submission of corrected data sheets from the laboratory. Summarize all actions taken in the Data Validation Report.
- 3) Transcription errors that affect the data shall be noted in Data Validation Report. Also, the laboratory shall be contacted and the submission of corrected data sheets shall be requested.
- 4) If the percent solids data were not provided then note the deficiency in the data validation report. The results are qualified and possibly biased low.
- 5) If the pH readings are not provided, then contact the laboratory. The data are conditionally rejected pending satisfactory verification of the pH results.
- 6) If the laboratory failed to record the pH data in a laboratory notebook, then the

following actions are taken:

- a) The data are qualified with an unknown bias if the positive results exceed the clean-up action level.
 - b) The data are suspect if the positive results are below the clean-up action level.
 - c) The "non-detected" data are rejected because the possibility of false NDs exists.
- 7) If the sample digestion solution temperature readings are not provided, then contact the laboratory. The data are conditionally rejected pending satisfactory verification of the digestion solution temperature.
- 8) If the laboratory failed to record the sample digestion solution temperature in a laboratory notebook, then the following actions are taken:
- a) The data are qualified with an unknown bias if the positive results exceed the clean-up action level.
 - b) The data are suspect if the positive results are below the clean-up action level.
 - c) The "non-detected" data are rejected because the possibility of false NDs exists.
- 7) For Method 7199, if the samples were not injected twice, then qualify the affected sample.
- 8) For Method 7199, if the sample was injected twice but relative standard deviation of the duplicates was > 20 % RPD, then qualify the affected sample.

APPENDIX I - GLOSSARY OF TERMS

ABSORBANCE - a measure of decrease in incident light passing through a sample into the detector. It is defined mathematically as:

$$A = \frac{I(\text{solvent})}{I(\text{solution})} = \log \frac{I_0}{I}$$

Where, I = radiation intensity

ALiquot- a measured portion of a field sample taken for analysis.

ANALYSIS DATE/TIME - the date and military time (24-hour clock) of the injection of the sample, standard, or blank into the analysis system.

ANALYTE - the element or ion an analysis seeks to determine; the element of interest.

AUTOZERO - zeroing the instrument at the proper wavelength. It is equivalent to running a standard blank with the absorbance set at zero.

AVERAGE INTENSITY - the average of two different injections (exposures).

BACKGROUND CORRECTION - a technique to compensate for variable background contribution to the instrument signal in the determination of trace elements.

BATCH - the basic unit for analytical quality control is the analytical batch. The analytical batch is defined as 20 samples or less which are analyzed together with the same method sequence and the same lots of reagents and the manipulations common to each sample within the same time period or in continuous sequential time periods. Samples in each batch should be of similar composition (e.g. groundwater, sludge, ash, etc.).

CALIBRATION - the establishment of an analytical curve based on the absorbance, emission intensity, or other measured characteristic of known standards. The calibration standards must be prepared using the same type of reagents as used in the sample preparation.

CALIBRATION BLANK - a volume of digestion solution/distilled water.

CALIBRATION CHECK STANDARD - analytical standard run every 10 analytical samples to verify the calibration of the analytical system.

COEFFICIENT OF VARIATION (CV) - the standard deviation as a percent of the arithmetic mean.

CONTROL LIMITS - a range within which specified measurement results must fall to be compliant. Control limits may be mandatory, requiring corrective action if exceeded, or advisory, requiring that noncompliant data be flagged.

CORRELATION COEFFICIENT - a number (r) which indicates the degree of dependence between two variables (concentration - absorbance). The more dependent they are the closer the value to one. Determined based on the least squares line.

DAY - unless otherwise specified, day shall mean calendar day.

DIGESTION LOG - an official record of the sample preparation (digestion).

DUPLICATE - a second aliquot of a sample that is treated the same as the original sample in order to determine the precision of the method.

FIELD BLANK – an analytical sample design to assess specific sources of field contamination.

HOLDING TIME - the elapsed time expressed in days from the date of sample collection until the date of its analysis.

$$\text{Holding time} = (\text{sample analysis date} - \text{sampling date})$$

INDEPENDENT STANDARD - a laboratory-prepared standard solution that is composed of Hexavalent Chromium from a different source other than that used in the standards for the initial calibration.

INJECTION - introduction of the analytical sample into the instrument excitation system for the purpose of measuring absorbance, emission or concentration of an analyte. May also be referred to as exposure.

INSTRUMENT DETECTION LIMIT (IDL) - determined by multiplying by three the standard deviation obtained for the analysis of a standard solution (each analyte in reagent water) at a concentration of 3x-5x IDL on three nonconsecutive days with seven consecutive measurements per day.

INTERFERENTS - substances which affect the analysis for the element of interest.

MATRIX - the predominant material of which the sample to be analyzed is composed.

MATRIX SPIKE - aliquot of a sample (water or soil) fortified (spiked) with known quantities of specific compounds and subjected to the entire analytical procedure in order to indicate the appropriateness of the method for the matrix by measuring recovery.

METHOD DETECTION LIMIT (MDL) - The minimum concentration of a substance that can be measured and reported with 99 % confidence that the analyte concentration is greater than zero and is determined from analysis of a sample in a given matrix containing the analyte. The procedures for determining the MDL are located in Chapter 1 of SW-846.

PREPARATION BLANK (reagent blank, method blank) - an analytical control that contains distilled, deionized water and reagents, which is carried through the entire analytical procedure (digested and analyzed). An aqueous method blank is treated with the same reagents as a sample with a water matrix; A solid method blank is treated with the same reagents as a soil sample.

PROTOCOL - a compilation of the procedures to be followed with respect to sample receipt and handling, analytical methods, data reporting and deliverables, and document control.

ROUNDING RULES - if the figure following those to be retained is less than 5, the figure is dropped, and the retained figures are kept unchanged. As an example, 11.443 is rounded off to 11.44.

If the figure following those to be retained is greater than 5, the figure is dropped, and the last retained figure is raised by 1. As an example, 11.446 is rounded off to 11.45.

If the figure following those to be retained is 5, and if there are no figures other than zeros beyond the five, the figure 5 is dropped, and the last-place figure retained is increased by one if it is an odd number or it is kept unchanged if an even number. As an example, 11.435 is rounded off to 11.44, while 11.425 is rounded off to 11.42.

If a series of multiple operations is to be performed (add, subtract, divide, multiply), all figures are carried through the calculations. Then the final answer is rounded to the proper number of significant figures.

RUN - a continuous analytical sequence consisting of prepared samples and all associated quality assurance measurements as required by the USEPA, SW-846.

SOIL - synonymous with soil/sediment or sediment as used herein.

SPECTROMETER - An instrument with an entrance slit, a dispersing device, and one or more exit slits, in which measurements are made at selected wavelengths within the spectral range, or by scanning over the range.

STOCK SOLUTION - a standard solution which can be diluted to derive other standards.

WET WEIGHT - the weight of a sample aliquot including moisture (undried).

INTRODUCTION

This document is designed to offer the data reviewer guidance in determining the usability of analytical data generated through the USEPA Contract Laboratory Program (CLP) Statement of Work (SOW) ISM01.X Inorganic Superfund Methods (Multi-Media, Multi-Concentration), hereinafter referred to as the ISM01.2 SOW, and any future editorial revisions of ISM01.2. This guidance is somewhat limited in scope and is intended to be used as an aid in the formal technical review process. It should not be used to establish specific contract compliance; use of this document to evaluate data generated under Inorganic SOWs other than ISM01.2 is cautioned. Definitive guidance is provided where performance should be fully under a laboratory's control [e.g., blanks, calibration verification standards, Interference Check Samples (ICSs), Quality Control (QC) audit samples, and instrument performance checks (tuning)], while general guidance is provided for evaluating subjective data that is affected by site conditions.

The guidelines presented in the document will aid the data reviewer in establishing (a) if data meets the specific technical and QC criteria established in the SOW, and (b) the usability and extent of bias of any data not meeting the specific technical and QC criteria established in the SOW. It must be understood by the reviewer that acceptance of data not meeting technical requirements is based upon many factors, including, but not limited to site-specific technical requirements, the need to facilitate the progress of specific projects, and availability for re-sampling. To make judgments at this level requires the reviewer to have a complete understanding of the intended use of the data. The reviewer is strongly encouraged to establish a dialogue with the user prior to and after data review, to discuss usability issues and to answer questions regarding the review. It should also be understood that in all cases, data which do not meet specified criteria are never to be fully acceptable without qualification.

The reviewer should note that while this document is to be used as an aid in the formal data review process, other sources of guidance and information, as well as professional judgment, should also be used to determine the ultimate usability of data, especially in those cases where all data does not meet specific technical criteria. The reviewer should also be aware that minor modifications to some of the analytical methods may be made through the "Request for Quote (RFQ) for Modified Analysis" to meet site-specific requirements, and that these modifications could affect certain validation criteria such as Contract Required Quantitation Limits (CRQLs) and Target Analyte Lists (TALs). A copy of any modification request made to the analytical method should be included in the data package by the laboratory.

Please visit the CLP Web site at <http://www.epa.gov/superfund/programs/clp/index.htm> for more information on how to obtain service through the CLP.

DATA QUALIFIER DEFINITIONS

The following definitions provide brief explanations of the national qualifiers assigned to results in the data review process. If the Regions choose to use additional qualifiers, a complete explanation of those qualifiers should accompany the data review.

U	The analyte was analyzed for, but was not detected above the level of the reported sample quantitation limit.
J	The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.
J+	The result is an estimated quantity, but the result may be biased high.
J-	The result is an estimated quantity, but the result may be biased low.
R	The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.
UJ	The analyte was analyzed for, but was not detected. The reported quantitation limit is approximate and may be inaccurate or imprecise.

DATA PACKAGE INSPECTION

For data obtained through the Contract Laboratory Program (CLP), the Data Assessment Tool (DAT) report is a useful tool in the data review process. The DAT report incorporates Contract Compliance Screening (CCS) and National Functional evaluation results, and is transmitted electronically via email. For more information about DAT, please refer to the following CLP Web site:

http://www.epa.gov/superfund/programs/clp/data_assessment.htm

The DAT report will identify any missing and/or incorrect information in the data package. The CLP laboratory may submit a reconciliation package for any missing items or to correct data.

If there are any concerns regarding the data package, contact the CLP Project Officer (CLP PO) from the Region where the samples were taken. For personnel contact information, please refer to the following CLP Web site:

<http://www.epa.gov/superfund/programs/clp/contacts.htm>

PRELIMINARY REVIEW

This document is for the review of analytical data generated through the ISM01.2 SOW and any future editorial revisions of ISM01.2. To use this document effectively, the reviewer should have an understanding of the analytical method and a general overview of the Sample Delivery Group (SDG) or sample Case at hand. The exact number of samples, their assigned numbers, their matrix, and the number of laboratories involved in the analysis are essential information.

It is suggested that an initial review of the data package be performed, taking into consideration all information specific to the sample data package [e.g., Modified Analysis requests, Traffic Report/Chain of Custody (TR/COC) documentation, SDG Narratives, etc.].

The reviewer should also have a copy of the Quality Assurance Project Plan (QAPP) or similar document for the project for which the samples were analyzed. The reviewer should contact the appropriate Regional Contract Laboratory Program Project Officer (CLP PO) to obtain copies of the QAPP and relevant site information. This information is necessary in determining the final usability of the analytical data.

The SDGs or Cases routinely have unique samples that require special attention from the reviewer. These include field blanks and trip blanks, field duplicates, and Performance Evaluation (PE) samples which must be identified in the sampling records. The sampling records (e.g., TR/COC records, field logs, and/or contractor tables) should identify:

1. The Region where the samples were taken, and
2. The complete list of samples with information on:
 - a. Sample matrix;
 - b. Field blanks*;
 - c. Field duplicates*;
 - d. Field spikes*;
 - e. PE samples*;
 - f. Shipping dates;
 - g. Preservatives;
 - h. Types of analysis; and
 - i. Laboratories involved.

* If applicable.

The TR/COC documentation includes sample descriptions and date(s) of sampling. The reviewer must consider lag times between sampling and start of analysis when assessing technical sample holding times. The laboratory's SDG Narrative is another source of general information. Notable problems with matrices, insufficient sample volume for analysis or reanalysis, samples received in broken containers, preservation, and unusual events should be documented in the SDG Narrative. The reviewer should also inspect any email or telephone/communication logs detailing any discussion of sample or analysis issues between the laboratory, the CLP Sample Management Office (SMO), and the USEPA Region.

DATA REVIEW NARRATIVE

A Data Review Narrative, including the Inorganic Data Review Summary form (see Appendix B), must accompany the laboratory data forwarded to the intended data recipient (client) or user to promote communication. A copy of the Data Review Narrative should be submitted to the CLP PO assigned oversight responsibility for the laboratory producing the data.

The Data Review Narrative should include comments that clearly identify the problems associated with a Case or SDG and state the limitations of the data. Documentation should also include the CLP Sample Number, analytical method, extent of the problem, and assigned qualifiers.

ICP-AES DATA REVIEW

The inorganic data requirements for Inductively Coupled Plasma-Atomic Emission Spectroscopy (ICP-AES) to be reviewed during validation are listed below:

I.	Preservation and Holding Times	7
II.	Calibration	9
III.	Blanks	12
IV.	Inductively Coupled Plasma - Interference Check Sample (ICP-ICS)	15
V.	Laboratory Control Sample (LCS)	18
VI.	Duplicate Sample Analysis	20
VII.	Spike Sample Analysis	22
VIII.	ICP Serial Dilution	25
IX.	Regional Quality Assurance (QA) and Quality Control (QC)	27
X.	Overall Assessment	28
	Calculations for ICP-AES	30

Preservation and Holding Times

A. Review Items:

Form IA-IN, Form IB-IN, Form XII-IN, Form XIII-IN, Traffic Report/Chain of Custody (TR/COC) documentation, Form DC-1, raw data, and the Sample Delivery Group (SDG) Narrative checking for: pH; cooler temperature; holding time; and other sample conditions.

B. Objective:

The objective is to ascertain the validity of the analytical results based on the sample condition, and the holding time of the sample from the date of collection to the date of analysis.

C. Criteria:

1. The technical holding time criteria for aqueous/water metal samples is 180 days, preserved (with nitric acid) to $\text{pH} \leq 2$. The addition of nitric acid to adjust the pH is only required for aqueous/water samples.
2. The technical holding time criteria for soil/sediment metal samples is 180 days, based on the technical holding time criteria for aqueous/water samples.
3. The technical holding time criteria for wipe and air filter samples is 180 days, based on the technical holding time criteria for aqueous/water samples.
4. Aqueous/water and soil/sediment samples shall be maintained at 4°C ($\pm 2^{\circ}\text{C}$) until preparation. Wipe and air filter samples may be maintained at room temperature until preparation.

D. Evaluation:

Technical holding times are established by comparing the sampling date(s) on the TR/COC documentation with the dates of analysis on Form XIII-IN and the raw data. Information contained in the Complete SDG File (CSF) should also be considered in the determination of holding times. Verify that the analysis dates on the Form XIII-INs and the raw data are identical. Review the SDG Narrative and raw data preparation logs to determine if samples were properly preserved. If there is an indication that there were problems with the samples, the integrity of the samples may be compromised and professional judgment should be used to evaluate the effect of the problem on the sample results.

E. Action:

NOTE: Apply the action to each sample for which the preservation or holding time criteria was not met.

1. If the pH of aqueous/water metal samples is > 2 at the time of sample receipt, determine if the laboratory adjusted the pH of the sample to ≤ 2 at the time of sample receipt. If not, use professional judgment to qualify the samples based on the pH of the sample and the chemistry of the metal(s) of interest. Qualify results that are \geq Method Detection Limit (MDL) as estimated low (J-), and qualify non-detects as unusable (R).
2. If technical holding times are exceeded, use professional judgment to determine the reliability of the data, based on the magnitude of the additional time compared to the technical requirement and whether the samples were properly preserved. The expected bias would be low. Qualify results that are \geq MDL as estimated low (J-), and qualify non-detects as unusable (R).
3. Due to limited information concerning holding times for soil/sediment, wipe, and filter samples, it is left to the discretion of the data reviewer whether to apply aqueous/water holding time criteria to soil/sediment, wipe, or filter samples. If they are applied, it must be clearly documented in the Data Review Narrative.
4. When the holding times are exceeded, the reviewer should comment in the Data Review Narrative on any possible consequences for the analytical results.
5. When holding times are grossly exceeded, note it for Contract Laboratory Program Project Officer (CLP PO) action.

Table 1. Technical Holding Time Actions for ICP-AES Analysis

Preservation & Holding Time Results	Action for Samples
Aqueous/water metals samples received with pH > 2 and pH not adjusted	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Aqueous/water and soil/sediment metals samples not maintained at 4°C ($\pm 2^\circ\text{C}$)	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Aqueous/water Metals > 180 day	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Soil/sediment, wipe, filter Metals > 180 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

Calibration

A. Review Items:

Form II-IN (Part A), Form XI-IN, Form XIII-IN, Form XVI-IN, preparation logs, calibration standard logs, instrument logs, instrument printouts, and raw data.

B. Objective:

Method requirements for satisfactory instrument calibration are established to ensure that the instrument is capable of producing acceptable quantitative data for the metals on the Inorganic Target Analyte List (TAL). Initial Calibration Verification (ICV) demonstrates that the instrument is capable of acceptable performance at the beginning of the analytical run. Continuing Calibration Verification (CCV) demonstrates that the initial calibration is still valid by checking the performance of the instrument on a continuing basis.

C. Criteria:

1. Initial Calibration

The instruments shall be successfully calibrated each time the instrument is set up and after Continuing Calibration Verification (CCV) failure. The calibration date and time shall be included in the raw data.

- a. A blank and at least five calibration standards shall be used to establish each analytical curve. At least one of these standards shall be at or below the CRQL. All measurements shall be within the instrument working range where the interelement correction factors are valid. A minimum of three replicate exposures are required for standardization, all Quality Control (QC), and sample analyses. The average result of all the multiple exposures for the standardization, QC, and sample analyses shall be used. The calibration curve shall be fitted using linear regression or weighted linear regression. The curve may be forced through zero. The curve must have a correlation coefficient ≥ 0.995 . The percent differences calculated for all of the non-zero standards must be within $\pm 30\%$ of the true value of the standard. The y-intercept of the curve must be less than the CRQL.

2. Initial and Continuing Calibration Verification (ICV and CCV)

The acceptance criteria for the ICVs and CCVs are presented in Table 2:

Table 2. Acceptance Criteria for ICVs and CCVs,

Analytical Method	Inorganic Analytes	ICV/CCV Low Limit (% of True Value)	ICV/CCV High Limit (% of True Value)
ICP-AES	Metals	90	110

a. Initial Calibration Verification (ICV)

- 1) Immediately after each system has been calibrated, the accuracy of the initial calibration must be verified and documented for each target analyte by the analysis of an ICV solution(s). If the ICV %R falls outside of the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and all affected samples reanalyzed.
- 2) Only if the ICV is not available from USEPA, analyses shall be conducted using a certified solution of the analytes from an independent commercial standard source, at a concentration level other than that used for instrument calibration, but within the calibrated range.
- 3) The ICV solution shall be run at each analytical wavelength used for analysis.

b. Continuing Calibration Verification (CCV)

- 1) To ensure accuracy during the course of each analytical run, the CCV shall be analyzed and reported for each wavelength used for the analysis of each analyte.
- 2) The CCV standard shall be analyzed at a frequency of every two hours during an analytical run. The CCV standard shall also be analyzed at the beginning of the run, and again after the last analytical sample.
- 3) The analyte concentration(s) in the CCV standard(s) shall be different than the concentration used for the ICV, and at a concentration equivalent to the mid level of their respective calibration curves.
- 4) The same CCV standard solution shall be used throughout the analysis runs for a Sample Delivery Group (SDG).
- 5) The CCV shall be analyzed in the same fashion as an actual sample. If the %R of the CCV was outside of the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and all analytical samples analyzed since the last compliant CCV reanalyzed.

D. Evaluation:

1. Verify that the instrument was calibrated each time the instrument was set up, utilizing a blank and at least five calibration standards, one of which was at or below the CRQL.
2. Confirm that the measurements were within the working range, and were the average result of at least three replicate exposures.
3. Verify that the ICV and CCV standards were analyzed for each analyte at the proper frequency and at the appropriate concentration. Verify that acceptable %R results were obtained.
4. Recalculate one or more of the ICV and CCV %R using the following equation and verify that the recalculated value agrees with the laboratory-reported values on Form IIA-IN.

$$\%R = \frac{\text{Found (value)}}{\text{True (value)}} \times 100$$

Where,

- Found (value) = Concentration (in µg/L) of each analyte measured in the analysis of the ICV or CCV solution
- True (value) = Concentration (in µg/L) of each analyte in the ICV or CCV source

E. Action:

NOTES: For initial calibrations or ICVs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCVs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the QC sample and a subsequent technically acceptable analysis of the QC sample in the analytical run.

1. If the instrument was not calibrated each time the instrument was set up, qualify the data as unusable (R). If the instrument was not calibrated with at least the minimum number of standards, or if the calibration curve does not include standards at required concentrations (e.g., a blank and at least one at or below CRQL), use professional judgment to qualify results that are \geq Method Detection Limit (MDL) as estimated (J) or unusable (R), and non-detects as estimated (UJ) or unusable (R).
2. If the correlation coefficient is <0.995 , percent differences are outside the $\pm 30\%$ limit, or the y-intercept \geq CRQL, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).

3. If the ICV or CCV %R falls outside the acceptance windows, use professional judgment to qualify all associated data. If possible, indicate the bias in the review. The following guidelines are recommended:
 - a. If the ICV or CCV %R is $< 75\%$, qualify non-detects as unusable (R). Use professional judgment to qualify all results that are \geq MDL as estimated low (J-) or unusable (R).
 - b. If the ICV or CCV %R falls within the range of 75-89%, qualify sample results that are \geq MDL as estimated low (J-), and qualify non-detects as estimated (UJ).
 - c. If the ICV or CCV %R falls within the range of 111-125%, qualify sample results that are \geq MDL as estimated high (J+).
 - d. If the ICV or CCV %R is within the range of 111-125%, non-detects should not be qualified.
 - e. If the ICV or CCV %R is $> 125\%$, use professional judgment to qualify results that are \geq MDL as estimated high (J+) or unusable (R). Non-detects should not be qualified.
 - f. If the %R is $> 160\%$, qualify all results that are \geq MDL as unusable (R).
4. If the laboratory failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
5. Note the potential effects on the reported data due to exceeding the calibration criteria in the Data Review Narrative.
6. If calibration criteria are grossly exceeded, note this for CLP Project Officer (CLP PO) action.

NOTE: For truly critical samples, a further in-depth evaluation of the calibration curve may be warranted to determine if additional qualification is necessary.

Table 3. Calibration Actions for ICP-AES Analysis

Calibration Result	Action for Samples
Calibration not performed	Qualify all results as unusable (R)
Calibration incomplete	Use professional judgment Qualify results that are \geq MDL as estimated (J) or unusable (R) Qualify non-detects as estimated (UJ) or unusable (R)
Correlation coefficient < 0.995 ; %D outside $\pm 30\%$; y-intercept \geq CRQL	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
ICV/CCV %R $< 75\%$	Qualify results that are \geq MDL as estimated low (J-) or unusable (R) Qualify all non-detects as unusable (R)
ICV/CCV %R 75-89%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICV/CCV %R 111-125%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R $> 125\%$	Qualify results that are \geq MDL as estimated high (J+) or unusable (R)
ICV/CCV %R $> 160\%$	Qualify results that are \geq MDL as unusable (R)

Blanks

A. Review Items:

Form I-IN, Form III-IN, Form XII-IN, Form XIII-IN, preparation logs, calibration standard logs, instrument logs, and raw data.

B. Objective:

The objective of blank analysis results assessment is to determine the existence and magnitude of contamination resulting from laboratory (or field) activities. The criteria for evaluation of blanks apply to any blank associated with the samples (e.g., method blanks, calibration blanks, field blanks, etc.). If problems with any blank exist, all associated data must be carefully evaluated to determine whether or not there is an inherent variability in the data, or if the problem is an isolated occurrence not affecting other data.

C. Criteria:

1. No contaminants should be found in the blank(s).
2. The Initial Calibration Blank (ICB) shall be analyzed after the analytical standards, but not before analysis of the Initial Calibration Verification (ICV) during the initial calibration of the instrument (see Section II.C.1).
3. A Continuing Calibration Blank (CCB) shall be analyzed at each wavelength used for the analysis, immediately after every Continuing Calibration Verification (CCV). The CCB shall be analyzed at a frequency of every two hours during the run. The CCB shall be analyzed at the beginning of the run, and again after the last CCV that was analyzed after the last analytical sample of the run. The CCB result (absolute value) shall not exceed the Contract Required Quantitation Limit (CRQL) of each analyte for which analysis is performed.
4. At least one Preparation Blank shall be prepared and analyzed for each matrix, with every Sample Delivery Group (SDG), or with each batch of samples digested, whichever is more frequent. The Preparation Blank consists of reagent water or a clean wipe or filter processed through the appropriate sample preparation and analysis procedure.
5. If any analyte concentration in the Preparation Blank is $> \text{CRQL}$, the lowest concentration of that analyte in the associated samples must be ≥ 10 times ($10x$) the Preparation Blank concentration. Otherwise, all samples associated with that Preparation Blank with the analyte's concentration $< 10x$ the Preparation Blank concentration, and $> \text{CRQL}$, should be redigested and reanalyzed for that analyte (except for an identified field blank). The laboratory is not to correct the sample concentration for the blank value.
6. If the concentration of the Preparation Blank for a certain analyte is $< (-\text{CRQL})$ all samples reported $< 10x$ the CRQL (associated with that analyte in that blank), should be redigested and reanalyzed.

D. Evaluation:

1. Verify that an ICB was analyzed after the calibration, the CCB was analyzed at the proper frequency and location during the run, and Preparation Blanks were prepared and analyzed as appropriate for the SDG (e.g., total number of samples, various types of matrices present, number of digestion batches, etc.).
2. Review the results reported on the Blank Summary (Form III-IN), as well as the raw data for all blanks, and verify that the results were accurately reported.
3. Evaluate all of the associated blanks for the presence of target analytes. Verify that if target analytes were present in a Preparation Blank or if a concentration was $< (-\text{CRQL})$ the affected samples were redigested and reanalyzed. Verify that if target analytes were present in an ICB or a CCB, the analysis was terminated, the problem corrected, the instrument recalibrated, and the preceding 10 analytical samples or all analytical samples analyzed since the last compliant calibration blank reanalyzed.

E. Action:

NOTES: For ICBs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCBs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the CCB and a subsequent technically acceptable analysis of the CCB in the analytical run.

For Preparation Blanks that do not meet the technical criteria, apply the action to all samples prepared in the same preparation batch.

1. If the appropriate blanks were not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank (including Preparation Blanks) reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank (including Preparation Blanks) reported with a negative result, whose value is $<$ (-CRQL) qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. Specific “method” actions include:
 - a. If the absolute value of an ICB or a CCB result is $>$ CRQL, the analysis should be terminated. If the analysis was not terminated and the affected samples were not reanalyzed, report non-detects and results that are \geq MDL, but \leq CRQL as CRQL-U. For results that are $>$ CRQL but $<$ Blank Result, use professional judgment to qualify the data as unusable (R) or to report the results at the level of the blank with a “U” qualifier. Use professional judgment to qualify results that are $>$ Blank Result. Note this situation for CLP PO action and record it in the Data Review Narrative.
 - b. If the absolute value of the concentration of the Preparation Blank is \leq CRQL, report non-detects and results that are \geq MDL but \leq CRQL as CRQL-U. Use professional judgment to qualify results that are $>$ CRQL.
 - c. If any analyte concentration in the Preparation Blank is $>$ CRQL, the lowest concentration of that analyte in the associated samples must be 10x the Preparation Blank concentration. Otherwise, all samples associated with that blank with concentrations $<$ 10x the Preparation Blank concentration and $>$ CRQL should be redigested and reanalyzed. Raise the CRQL to the concentration found in the Preparation Blank and report those samples that do not require redigestion (that are \geq MDL but \leq CRQL) as CRQL-U. Note for CLP PO action and record in the Data Review Narrative if the laboratory failed to redigest and reanalyze the affected samples. The reviewer shall then use professional judgment to assess the data.

Table 4. Blank Actions for ICP-AES Analysis

Blank Type	Blank Result	Sample Result	Action for Samples
ICB/CCB	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
ICB/CCB	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ Blank Result	Report at level of Blank Result with a "U" or qualify data as unusable (R)
		$>$ Blank Result	Use professional judgment
ICB/CCB	\leq (-MDL) but \geq (-CRQL)	\geq MDL, or non-detect	Use professional judgment
ICB/CCB	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)
Preparation Blank	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ 10x the Blank Result	Use professional judgment to qualify results as unusable (R) or estimated high (J+)
		\geq 10x the Blank Result	No action
Preparation Blank	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
Preparation Blank	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)

Inductively Coupled Plasma - Interference Check Sample (ICP-ICS)

A. Review Items:

Form IVA-IN, Form XIII-IN, instrument printouts, and raw data.

B. Objective:

The Inductively Coupled Plasma (ICP) - Interference Check Sample (ICS) verifies the analytical instrument's ability to overcome interferences typical of those found in samples.

NOTE: The laboratory should have analyzed and reported ICS results for all elements being reported from the analytical run and for all interferents (target and non-target) for these reported elements.

C. Criteria:

1. The ICS consists of two solutions: Solution A and Solution AB. Solution A consists of the interferents, and Solution AB consists of the analytes mixed with the interferents. An ICS analysis consists of analyzing both solutions consecutively, starting with Solution A, for all wavelengths used for each analyte reported by Inductively Coupled Plasma - Atomic Emission Spectroscopy (ICP-AES).
2. An ICS must be run at the beginning of each sample analysis run. The ICS is not to be run prior to the Initial Calibration Verification (ICV), and is to be immediately followed by a Continuing Calibration Verification (CCV), which will be followed by a Continuing Calibration Blank (CCB).
3. Results for the analysis of ICS Solution A must fall within the control limits of \pm Contract Required Quantitation Limit (CRQL), or $\pm 20\%$ of the true value (whichever is greater) for the analytes and interferents.
4. Results for the analysis of ICS Solution AB must fall within the control limits of \pm CRQL, or $\pm 20\%$ of the true value (whichever is greater) for the analytes and interferents included in the solution.
5. If the value of an ICS result exceeds \pm CRQL, or $\pm 20\%$ of true value (whichever is greater) criteria, the analysis shall be terminated, the problem corrected, the instrument recalibrated, the new calibration then reverified, and the affected samples reanalyzed.
6. The ICS should be obtained from USEPA if available, and analyzed according to the instructions supplied with the solutions. The ICS may be prepared with the interferents at 2x the level specified in the Statement of Work (SOW) if high levels of interferents are found in the field samples. If the ICS is not available from USEPA, an independent ICS solution shall be prepared with the interferent and analyte concentrations at the levels specified in the method.

D. Evaluation:

1. Verify using the raw data (ICP instrument printout) that the ICS was analyzed at the proper frequency and location during the analytical run.
2. Evaluate the ICS raw data for results with an absolute value that is \geq Method Detection Limit (MDL) for those analytes which are not present in the ICS solution.
3. Recalculate using the raw data and the following equation, one or more of the analyte Percent Recoveries (%R), and verify that the recalculated value agrees with the laboratory-reported values on Form IV-IN.

$$\%R = \frac{\text{Found (value)}}{\text{True (value)}} \times 100$$

Where,

- Found (value) = Concentration (in $\mu\text{g/L}$) of each analyte interferent measured in the analysis of ICS Solution A or ICS Solution AB
- True (value) = Concentration (in $\mu\text{g/L}$) of each analyte or interferent in ICS Solution A or ICS Solution AB

4. If the value of an ICS result exceeds the \pm CRQL, or \pm 20% of true value (whichever is greater) criteria, and the laboratory failed to terminate the analysis, and take the appropriate corrective action, note this for Contract Laboratory Program Project Officer (CLP PO) action and record in the Data Review Narrative. Use professional judgment to assess the data.

E. Action:

NOTE: For an ICS that does not meet the technical criteria, apply the action to all samples analyzed in the analytical run.

1. The raw data should, but may not, contain results for interferences. If not, the reviewer shall use professional judgment to qualify the data. If the data does contain results for interferences, the reviewer should apply the following actions to samples with concentrations of interferences that are comparable to, or greater than, their respective levels in the ICS:
 - a. If the ICS %R for an analyte or interference is $> 120\%$ (or greater than the true value + CRQL, as applicable) and the sample results are non-detects, the data should not be qualified.
 - b. If the ICS %R for an analyte or interference is $> 120\%$ (or greater than the true value + CRQL, as applicable) qualify sample results that are \geq MDL as estimated high (J+). If the ICS %R (or true value) grossly exceeds the limits, use professional judgment to qualify the data.
 - c. If the ICS %R for an analyte or interference falls within the range of 50-79% (or less than the true value - CRQL, as applicable) qualify sample results that are \geq MDL as estimated low (J-).
 - d. If the ICS recovery for an analyte falls within the range of 50-79% (or less than the true value - CRQL, as applicable), the possibility of false negatives exists. Qualify sample non-detects as estimated (UJ).
 - e. If the ICSAB %R for an analyte or interference is $< 50\%$, qualify all sample results that are \geq MDL as estimated low (J-) and all sample non-detects as unusable (R).
2. If results that are \geq MDL are observed for analytes that are not present in the ICS solution, the possibility of false positives exists. An evaluation of the associated sample data for the affected elements should be made. For samples with comparable or higher levels of interferences and with analyte concentrations that approximate those levels found in the ICS, qualify sample results that are \geq MDL as estimated high (J+). Non-detects should not be qualified.
3. If negative results are observed for analytes that are not present in the ICS solution, and their absolute value is \geq MDL, the possibility of false negatives in the samples exists. An evaluation of the associated sample data for the affected analytes should be made. For samples with comparable or higher levels of interferences, qualify non-detects for the affected analytes as estimated (UJ), and results that are \geq MDL but $< 10x$ the absolute value of the negative result as estimated low (J-).

4. In general, ICP-AES sample data can be accepted if the concentrations of Al, Ca, Fe, and Mg in the sample are found to be less than or equal to their respective concentrations in the ICS. If these elements are present at concentrations greater than the level in the ICS, or other elements are present in the sample at > 10 mg/L, the reviewer should investigate the possibility of other interference effects as given in the ICP-AES method or as indicated by the laboratory's interelement correction factors reported on Forms XA-IN and XB-IN for that particular instrument. The analyte concentration equivalents presented in the method should be considered only as estimated values since the exact value of any analytical system is instrument-specific. Therefore, estimate the concentration produced by an interfering element. If the estimate is > 2x the CRQL, and also > 10% of the reported concentration of the affected element, qualify the affected results as estimated (J).
5. If the raw data does not contain results for the interferents, note it in the Data Review Narrative.
6. Actions regarding the interpretation and/or the subsequent qualification of ICP data due to the ICS analytical results can be extremely complex. Use professional judgment to determine the need for the associated sample data to be qualified. The reviewer may need to obtain additional information from the laboratory. All interpretive situations should then be recorded in the Data Review Narrative.
7. If the ICS acceptance criteria are grossly exceeded, note the specifics for CLP PO action.

Table 5. Interference Check Actions for ICP-AES Analysis

Interference Check Sample Results	Action for Samples
ICS %R > 120% (or greater than true value + CRQL)	Qualify results that are \geq MDL as estimated high (J+)
ICS %R 50-79% (or less than true value - CRQL)	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICSAB %R < 50%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Potential false positives in field samples with interferents	Qualify results that are \geq MDL as estimated high (J+)
Potential false negatives in field samples with interferents	Qualify results that are \geq MDL but < 10x(negative value) as estimated low (J-) Qualify non-detects as estimated (UJ)

Laboratory Control Sample (LCS)

A. Review Items:

Form VII-IN, Form XII-IN, preparation logs, instrument printouts, and raw data.

B. Objective:

The Laboratory Control Sample (LCS) serves as a monitor of the overall performance of each step during the analysis, including the sample preparation.

C. Criteria:

1. Aqueous/water, soil/sediment, wipe, and filter LCSs shall be analyzed for each analyte utilizing the same sample preparations, analytical methods, and Quality Assurance/Quality Control (QA/QC) procedures as employed for the samples.
 - a. One LCS shall be prepared and analyzed for every group of aqueous/water or soil/sediment samples in a Sample Delivery Group (SDG), or with each batch of samples digested, whichever is more frequent. The LCS shall be spiked such that the final digestate contains each analyte at two times the CRQL for the associated matrix.
 - b. All LCS Percent Recoveries (%R) must fall within the control limits of 70-130%, except for Sb and Ag which must fall within the control limits of 50-150%. If the %R for the aqueous/water and soil/sediment LCS falls outside of the control limits, the analysis should be terminated, the problem corrected, and the samples prepared with that LCS redigested and reanalyzed.
 - c. One LCS shall be prepared and analyzed for each group of wipe or filter samples in an SDG, or with each batch of wipe or filter samples digested, whichever is more frequent. The wipe or filter LCS shall be spiked such that the final digestate contains each analyte at two times the CRQL for the associated matrix.
 - d. All wipe or filter sample LCS %R shall fall within the control limits of 70-130%.

D. Evaluation:

1. Verify using Form VII-IN, Form XII-IN, and raw data that the appropriate number of required LCSs were prepared and analyzed for the SDG.
2. Evaluate Form VII-IN and verify that all results for each analyte fall within the established control limits.
 - a. Check the raw data to verify that the %Rs on Form VII-IN were accurately transcribed. Recalculate one or more of the reported %Rs using the following equation:

$$\%R = \frac{\text{Found (value)}}{\text{True (value)}} \times 100$$

Where,

Found (value) = Concentration of each analyte (in µg/L, mg/kg, or µg) measured in the analysis of the LCS

True (value) = Concentration of each analyte (in µg/L, mg/kg, or µg) in the LCS

3. Verify that the LCS was prepared at the same time as the associated samples using the same procedures.

E. Action:

If the LCS criteria are not met, the laboratory performance and method accuracy are in question. Professional judgment should be used to determine if the data should be qualified or rejected. The following guidance is suggested for qualifying sample data associated with an LCS that does not meet the required criteria.

For an LCS that does not meet the technical criteria, apply the action to all samples in the same preparation batch.

1. Aqueous/Water and Soil/Sediment LCS:

- a. If the LCS %R falls within the range of 40-69% (20-49% for Ag and Sb), qualify sample results that are \geq Method Detection Limit (MDL) as estimated low (J-). If the LCS %R is $>$ 130% (150% for Ag and Sb), qualify sample results that are \geq MDL as estimated high (J+).
- b. If the LCS recovery is $>$ 130% (150% for Ag and Sb) and the sample results are non-detects, the data should not be qualified.
- c. If the LCS recovery falls within the range of 40-69% (20-49% for Ag and Sb), qualify non-detects as estimated (UJ).
- d. If LCS %R is $<$ 40% ($<$ 20% for Ag and Sb), qualify all results that are \geq MDL as estimated low (J-) and all non-detects as unusable (R).
- e. If the LCS %R is $>$ 150% (170% for Ag and Sb), qualify all affected data (both detects and non-detects) as unusable (R).

2. Wipe/Filter LCS:

- a. If the LCS %R is in the range of 40-69%, qualify sample results that are \geq MDL as estimated low (J-) and qualify non-detects as estimated (UJ).
 - b. If the LCS %R is $<$ 40%, qualify all results that are \geq MDL as estimated low (J-) and all non-detects as unusable (R).
 - c. If the LCS %R is $>$ 130% and the sample results are non-detects, do not qualify the data.
 - d. If the LCS %R is $>$ 130%, qualify all results \geq MDL as estimated high (J+).
3. If a laboratory fails to analyze an LCS with each SDG, or if a laboratory consistently fails to generate acceptable LCS recoveries, note this for CLP Project Officer (CLP PO) action.
 4. Whenever possible, the potential effects on the data due to out-of-control LCS results should be noted in the Data Review Narrative.

Table 6. LCS Actions for ICP-AES Analysis

LCS Result	Action for Samples
Aqueous/Water and Soil/Sediment %R 40-69% (20-49% Ag, Sb)	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
Aqueous/Water and Soil/Sediment %R $>$ 130% (150% Ag, Sb)	Qualify results that are \geq MDL as estimated high (J+)
Aqueous/Water and Soil/Sediment %R $<$ 40% ($<$ 20% Ag, Sb)	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Aqueous/Water and Soil/Sediment %R $>$ 150% ($>$ 170% Ag, Sb)	Qualify all results as unusable (R)
Wipe/Filter %R 40-69%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
Wipe/Filter %R $>$ 130%	Qualify results that are \geq MDL as estimated high (J+)
Wipe/Filter %R $<$ 40%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

Duplicate Sample Analysis

A. Review Items:

Cover Page, Form VI-IN, Form XII-IN, instrument printouts, and raw data.

B. Objective:

The objective of duplicate sample analysis is to demonstrate acceptable method precision by the laboratory at the time of analysis. Duplicate analyses are also performed to generate data that determines the long-term precision of the analytical method on various matrices. Non-homogenous samples can impact the apparent method precision. However, aqueous/water samples are generally homogenous and most soil/sediment samples are homogenous within a factor of two or three.

C. Criteria:

1. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for duplicate sample analysis.
2. At least one duplicate sample shall be prepared and analyzed from each group of samples of a similar matrix type (e.g., water or soil) or for each Sample Delivery Group (SDG). Duplicates are not required for wipe or filter samples. Duplicates cannot be averaged for reporting on Form I-IN. Additional duplicate sample analyses may be required by USEPA Regional request. Alternately, the Region may require that a specific sample be used for the duplicate sample analysis.
3. A control limit of 20% for the Relative Percent Difference (RPD) shall be used for original and duplicate sample values \geq five times (5x) the Contract Required Quantitation Limit (CRQL).
4. A control limit of the CRQL shall be used if either the sample or duplicate value is $< 5x$ the CRQL. The absolute value of the control limit (CRQL) shall be entered in the "Control Limit" column on Form VI-IN. If both samples are non-detects, the RPD is not calculated for Form VI-IN.

NOTE: The above control limits are **method requirements** for duplicate samples, regardless of the sample matrix type. However, it should be noted that laboratory variability arising from the sub-sampling of non-homogenous soil samples is a common occurrence. Therefore, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., 35% RPD, 2x the CRQL) to be assessed against duplicate soil samples.

D. Evaluation:

1. Verify from the Cover Page, Form XII-IN, and the raw data that the appropriate number of required duplicate samples were prepared and analyzed for the SDG.
2. Evaluate Form VI-IN and the raw data to verify that all duplicate results for each analyte and method fall within the established control limits.
3. Verify that a field blank or PE sample was not used for duplicate analysis.
4. Check the raw data and recalculate one or more of the RPD values using the following equation to verify that the results were correctly reported on Form VI-IN:

$$RPD = \frac{|S - D|}{(S + D)/2} \times 100$$

Where,

- RPD = Relative Percent Difference
S = Sample Result (original)
D = Duplicate Result

E. Action:

NOTE: For a duplicate sample analysis that does not meet the technical criteria, apply the action to all samples of the same matrix if the reviewer considers the samples to be sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data when determining similarity, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions]. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar to the duplicate sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for the duplicate, and thus that only the field sample used to prepare the duplicate sample should be qualified.

1. If the appropriate number of duplicate samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for CLP Project Officer (CLP PO) action.
2. If the results from a duplicate analysis for a particular analyte fall outside the appropriate control limits, qualify sample results that are \geq Method Detection Limit (MDL) as estimated (J) and non-detects as estimated (UJ).
3. If a field blank or PE sample was used for the duplicate sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
4. Note the potential effects on the data due to out-of-control duplicate sample results in the Data Review Narrative.

Table 7. Duplicate Sample Actions for ICP-AES Analysis

Duplicate Sample Results	Action for Samples
Both original sample and duplicate sample $> 5x$ the CRQL and RPD $> 20\%$ *	Qualify those results that are \geq MDL that professional judgment determines to be affected as estimated (J) and non-detects as estimated (UJ)
Original sample or duplicate sample $\leq 5x$ the CRQL (including non-detects) and absolute difference between sample and duplicate $> CRQL$ *	Qualify those results that are \geq MDL that professional judgment determines to be affected as estimated (J) and non-detects as estimated (UJ)

- * The above control limits are **method requirements** for duplicate samples, regardless of the sample matrix type. However, it should be noted that laboratory variability arising from the sub-sampling of non-homogenous soil samples is a common occurrence. Therefore, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., 35% RPD, 2x the CRQL) to be assessed against duplicate soil samples.

Spike Sample Analysis

A. Review Items:

Cover Page, Form V-IN (Part A & B), Form XII-IN, instrument printouts, and raw data.

B. Objective:

The spiked sample analysis is designed to provide information about the effect of each sample matrix on the sample preparation procedures and the measurement methodology. Non-homogenous samples can impact the apparent method recovery. However, aqueous/water samples are generally homogenous and most soil/sediment samples are homogenous within a factor of two or three. If the spike is added to the sample before the digestion (e.g., prior to the addition of other reagents), it is referred to as a spiked sample, pre-digestion spike, or Matrix Spike. If the spike is added to the sample after the completion of the digestion procedures, it is referred to as a post-digestion spike, or analytical spike.

C. Criteria:

1. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for spiked sample analysis.
2. At least one spiked sample (pre-digestion) shall be prepared and analyzed from each group of samples with a similar matrix type (e.g., water or soil), or for each Sample Delivery Group (SDG). Matrix Spikes are not required for wipe or filter samples.
3. When the Matrix Spike recovery falls outside of the control limits and the sample result is < four times (4x) the spike added, a post-digestion spike shall be performed for those analytes that do not meet the specified criteria. An aliquot of the remaining unspiked sample shall be spiked at 2x the indigenous level or 2x the Contract Required Quantitation Limit (CRQL), whichever is greater.

NOTE: Post-digestion spikes are not required for Ag.

4. The spike Percent Recovery (%R) shall be within the established acceptance limits. However, spike recovery limits do not apply when the sample concentration is $\geq 4x$ the spike added. In such an event, the data shall be reported unflagged, even if the %R does not meet the acceptance criteria.
5. If the spiked sample analysis was performed on the same sample that was chosen for the duplicate sample analysis, spike calculations shall be performed using the results of the sample designated as the "original sample". The average of the duplicate results cannot be used for the purpose of determining %R.

NOTE: The final spike concentrations required for the various target analytes are presented in the methods described in the Statement of Work (SOW).

D. Evaluation:

1. Verify using the Cover Page, Form VA-IN, Form XII-IN, and raw data, that the appropriate number of required spiked samples were prepared and analyzed for the SDG.
2. Verify that a field blank or PE sample was not used for the spiked sample analysis.
3. Evaluate Form VA-IN and the raw data to verify that all pre-digestion spiked sample results for each required analyte fall within the established control limits. If not, verify that a post-digestion/post-distillation spike was prepared and analyzed.
4. Recalculate using the raw data, one or more of the %R using the following equation, and verify that the recalculated value agrees with the laboratory-reported values on Forms V (A & B)-IN:

$$\% \text{ Recovery} = \frac{\text{SSR} - \text{SR}}{\text{SA}} \times 100$$

Where,

- SSR = Spiked Sample Result
SR = Sample Result
SA = Spike Added

NOTE: When the sample concentration is < Method Detection Limit (MDL), use SR = 0 only for the purpose of calculating the %R. The actual spiked sample results, sample results, and %R (positive or negative) shall still be reported on Forms VA-IN and VB-IN.

E. Action:

NOTE: For a Matrix Spike that does not meet the technical criteria, apply the action to all samples of the same matrix, if the reviewer considers the samples sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions], in determining similarity. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar to the Matrix Spike sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for the Matrix Spike, and thus that only the field sample used to prepare the Matrix Spike sample should be qualified.

1. If the appropriate number of Matrix Spike samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for Contract Laboratory Program Project Officer (CLP PO) action.
2. If a field blank or PE sample was used for the spiked sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
3. If the Matrix Spike recovery does not meet the evaluation criteria and a required post-digestion spike was not performed, note this for CLP PO action.
4. If the Matrix Spike %R is < 30%, verify that a post-digestion spike was analyzed (if required). If the post-digestion spike %R is < 75% or is not performed, qualify sample results that are \geq MDL as estimated low (J-) and non-detects as unusable (R). If the post-digestion spike %R is \geq 75%, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
5. If the Matrix Spike %R is 30-74% and the sample results are \geq MDL, verify that a post-digestion spike was analyzed (if required). If the %R for the post-digestion is also < 75% or is not performed, qualify the affected data as estimated low (J-). If the %R for the post-digestion spike is \geq 75%, qualify the affected data as estimated (J).
6. If the Matrix Spike %R falls within the range of 30-74% and the sample results are non-detects, qualify the affected data as estimated (UJ).
7. If the Matrix Spike %R is > 125% and the reported sample results are non-detects, the sample data should not be qualified.

8. If the Matrix Spike %R is $> 125\%$ and the sample results are \geq MDL, verify that a post-digestion spike was analyzed if required. If the %R for the post-digestion spike is also $> 125\%$ or is not performed, qualify the affected data as estimated high (J+). If the %R for the post-digestion spike is $\leq 125\%$, qualify the affected data as estimated (J).
9. Note the potential effects on the data due to out-of-control spiked sample results in the Data Review Narrative.

Table 8. Spike Sample Actions for ICP-AES Analysis

Spike Sample Results	Action for Samples
Matrix Spike %R $< 30\%$ Post-digestion spike %R $< 75\%$	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R $< 30\%$ Post-digestion spike %R $\geq 75\%$	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-digestion Spike %R $< 75\%$	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-digestion spike %R $\geq 75\%$	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R $> 125\%$ Post-digestion spike %R $> 125\%$	Qualify affected results that are \geq MDL as estimated high (J+)
Matrix Spike %R $> 125\%$ Post-digestion spike %R $\leq 125\%$	Qualify affected results that are \geq MDL as estimated (J)
Matrix Spike %R $< 30\%$ No post-digestion spike performed (e.g., not required for Ag)	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R 30-74% No post-digestion spike performed (e.g., not required for Ag)	Qualify affected results that are \geq MDL as estimated low (J-) and non-detects as estimated (UJ)
Matrix Spike %R $> 125\%$ No post-digestion spike performed (e.g., not required for Ag)	Qualify affected results that are \geq MDL as estimated high (J+) Non-detects are not qualified

ICP Serial Dilution

A. Review Items:

Form I-IN, Form VIII-IN, instrument printouts, and raw data.

B. Objective:

The serial dilution of samples quantitated by Inductively Coupled Plasma - Atomic Emission Spectroscopy (ICP-AES) determines whether or not significant physical or chemical interferences exist due to sample matrix.

C. Criteria:

1. An ICP Serial Dilution analysis shall be performed on a sample from each group of samples with a similar matrix type (e.g., water, soil, wipe, or filter) or for each Sample Delivery Group (SDG), whichever is more frequent.
2. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for the ICP Serial Dilution analysis.
3. If the analyte concentration is sufficiently high [concentration in the original sample is > 50 times (50x) the Method Detection Limit (MDL)], the Percent Difference (%D) between the original determination and the serial dilution analysis (a five-fold dilution) after correction for dilution shall be less than 10.

NOTE: The above criteria are **method requirements** for serial dilution samples, regardless of the sample matrix type. However, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., %D < 15) to be assessed against serial dilution soil samples.

D. Evaluation:

1. Verify that a field blank or PE sample was not used for the serial dilution analysis.
2. Check the raw data and recalculate the %D using the following equation. Verify that the serial dilution analysis results, and the calculated %D results agree with the values reported by the laboratory on Form VIII-IN:

$$\% \text{ Difference} = \frac{|I - S|}{I} \times 100$$

Where,

I = Initial Sample Result
S = Serial Dilution Result

3. Check the raw data for any evidence of positive or negative interference (results from the diluted sample which are significantly different than the original sample), possibly due to high levels of dissolved solids in the sample, ionization effects, etc.

E. Action:

NOTE: For a serial dilution that does not meet the technical criteria, apply the action to all samples of the same matrix if the reviewer considers the samples sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions], in determining similarity. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar

to the serial dilution sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for serial dilution, and thus that only the field sample used to prepare the serial dilution sample should be qualified.

1. If the required %D criteria are not met, qualify all affected results that are \geq MDL as estimated (J) and all affected non-detects as estimated (UJ).
2. If evidence of positive or negative interference is found, use professional judgment to qualify the associated sample data. Note the potential effects on the reported data in the Data Review Narrative.
3. It should be noted for Contract Laboratory Program Project Officer (CLP PO) action and in the Data Review Narrative if a field blank or PE sample was used for the serial dilution analysis.

Table 9. Serial Dilution Actions for ICP-AES Analysis

Serial Dilution Result	Action for Samples
Sample concentration > 50x MDL and %D > 10*	Qualify affected results that are \geq MDL as estimated (J) Qualify affected non-detects as estimated (UJ)
Interferences present	Use professional judgment

* The above criteria are **method requirements** for serial dilution samples, regardless of the sample matrix type. However, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., %D < 15) to be assessed against serial dilution soil samples.

Regional Quality Assurance (QA) and Quality Control (QC)**A. Review Items:**

Form I-IN, instrument printouts, and raw data.

B. Objective:

Regional QA/QC samples refer to any QA and/or QC sample initiated by the Region, including field duplicate samples, Performance Evaluation (PE) samples, blind spikes and blind blanks. The use of these QA/QC samples is highly recommended (e.g., the use of field duplicates can provide information on sampling precision and homogeneity).

C. Criteria:

Criteria are determined by each Region.

D. Evaluation:

Evaluation procedures must follow the Region's Standard Operating Procedure (SOP) for data review. Each Region will handle the evaluation of PE samples on an individual basis. Compare results for PE samples to the acceptance criteria for the specific PE samples if possible.

Calculate the Relative Percent Difference (RPD) between field duplicates and provide this information in the Data Review Narrative.

E. Action:

Any action must be in accordance with Regional specifications and criteria for acceptable PE sample results. Note any unacceptable PE sample results for Contract Laboratory Program Project Officer (CLP PO) action.

Overall Assessment

A. Review Items:

Entire sample data package, data review results, preparation logs, calibration standard logs, instrument logs, instrument printouts, and raw data (including any confirmation data).

B. Objective:

1. The objective is to ensure that the reported sample quantitation results are accurate. It is appropriate for the data reviewer to make professional judgments and express concerns, as well as to comment on the validity of the overall data for a Case. This is particularly appropriate when there are several Quality Control (QC) criteria that are outside of the specification parameters. The additive nature of QC factors that fall outside of specification parameters is difficult to assess in an objective manner, but the reviewer has a responsibility to inform the user of data quality and data limitations to assist that user to avoid inappropriate use of the data, while not precluding any consideration of the data. If qualifiers other than those used in this document are necessary to describe or qualify the data, it is necessary to thoroughly document/explain the additional qualifiers used. The data reviewer would be greatly assisted in this endeavor if the acceptance or performance criteria were provided. The Inorganic Review Summary (see Appendix B) and supplementary documentation must be included with the review.

C. Criteria:

1. Review all available materials to assess the overall quality of the data, keeping in mind the additive nature of analytical problems.
2. Reported analyte concentrations must be quantitated according to the appropriate analytical method, as listed in the method.

D. Evaluation:

Examine the raw data to verify that correct calculations of the sample results were reported by the laboratory. Digestion logs, instrument printouts, etc., should be compared to the reported sample results recorded on the appropriate Inorganic Summary Forms (Form I-IN through Form XIII-IN).

1. Evaluate any technical problems not previously addressed.
2. Examine the raw data for any anomalies (e.g., baseline shifts, negative absorbance, omissions, illegibility, etc.).
3. Verify that appropriate methods and amounts were used in preparing the samples for analysis. If reduced volumes were used, verify that the laboratory had received Contract Laboratory Program Project Officer (CLP PO) approval for the use of the reduced volume.
4. Verify that there are no transcription or reduction errors [e.g., dilutions, Percent Solids (%S), sample weights, etc.] on one or more samples.
5. Verify that results fall within the calibrated range(s) of the Inductively Coupled Plasma (ICP) instrument(s).
6. If appropriate information is available, the reviewer may assess the usability of the data to assist the data user in avoiding inappropriate use of the data. Review all available information, including the Quality Assurance Project Plan (QAPP), focusing specifically on the acceptance or performance criteria, the Standard Operating Procedure(s) (SOPs), and communication with the user concerning the intended use and desired quality of these data.

E. Action:

1. Use professional judgment to determine if there is any need to qualify data which were not qualified based on the QC criteria previously discussed.

2. Write a brief Data Review Narrative to give the user an indication of the analytical limitations of the data. Note any discrepancies between the data and the Sample Delivery Group (SDG) Narrative for Contract Laboratory Program Project Officer (CLP PO) action. If sufficient information on the intended use and required quality of the data is available, the reviewer should include an assessment of the data usability within the given context.
3. If any discrepancies are found, the laboratory may be contacted by the Region's designated representative to obtain additional information for resolution. If a discrepancy remains unresolved, the reviewer may determine that qualification of the data is warranted.

Calculations for ICP-AES**Aqueous/Water Samples by Inductively Coupled Plasma-Atomic Emission Spectroscopy (ICP-AES):**

The concentrations determined in the digestate are to be reported in units of $\mu\text{g/L}$:

$$\text{Concentration (}\mu\text{g/L)} = C \times \frac{V_f}{V} \times \text{DF}$$

Where,

- C = Instrument value in $\mu\text{g/L}$ (The average of all replicate exposures.)
- V_f = Final digestion volume (mL)
- V = Initial aliquot amount (mL)
- DF = Dilution Factor

Soil/Sediment Samples by ICP-AES:

The concentrations determined in the digestate are to be reported on the basis of the dry weight of the sample, in units of mg/kg :

$$\text{Concentration (drywt.)(mg/kg)} = C \times \frac{V_f}{W \times S} \times \text{DF}/1000$$

Where,

- C = Instrument value in $\mu\text{g/L}$ (The average of all replicate exposures.)
- V_f = Final digestion volume (mL)
- W = Initial aliquot amount (g)
- S = % Solids/100 (see Exhibit D - Introduction to Analytical Methods, Section 1.6).
- DF = Dilution Factor

Adjusted Method Detection Limit (MDL)/Adjusted Contract Required Quantitation Limit (CRQL) Calculation:

To calculate the adjusted MDL or adjusted CRQL for aqueous/water samples, substitute the value of the MDL ($\mu\text{g/L}$) or CRQL ($\mu\text{g/L}$) into the "C" term in the equation above.

Calculate the adjusted MDL or adjusted CRQL for soil/sediment samples as follows:

$$\text{Adjusted Concentration (mg/kg)} = C \times \frac{W_M}{W \times S} \times \frac{V_f}{V_M} \times \text{DF}$$

Where,

- C = MDL or CRQL (mg/kg)
- W_M = Minimum method required aliquot amount (g) (1.00 g or 0.50 g)
- W = Initial aliquot amount (g)
- V_M = Method required final sample digestion volume (mL) (100 mL or 50 mL)
- V_f = Final digestion volume (mL)
- S = % Solids/100 (see Exhibit D - Introduction to Analytical Methods, Section 1.6).
- DF = Dilution Factor

Wipe/Filter Mass:

$$\text{Mass } (\mu\text{g}) = C \times V_f \times \text{DF} / 1000$$

Where,

- C = Instrument value in $\mu\text{g/L}$ (The average of all replicate exposures).
- V_f = Final digestion volume (mL)
- DF = Dilution Factor

ICP-MS DATA REVIEW

The inorganic data requirements for Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) to be reviewed during validation are listed below:

I.	Preservation and Holding Times	34
II.	ICP-MS Tune Analysis	36
III.	Calibration	38
IV.	Blanks	41
V.	Inductively Coupled Plasma - Interference Check Sample (ICP-ICS)	44
VI.	Laboratory Control Sample (LCS)	47
VII.	Duplicate Sample Analysis	49
VIII.	Spike Sample Analysis	51
IX.	ICP Serial Dilution	54
X.	ICP-MS Internal Standards	56
XI.	Regional Quality Assurance (QA) and Quality Control (QC)	58
XII.	Overall Assessment	59
	Calculations for ICP-MS	61

I. Preservation and Holding Times

A. Review Items:

Form IA-IN, Form IB-IN, Form XII-IN, Form XIII-IN, Traffic Report/Chain of Custody (TR/COC) documentation, Form DC-1, raw data, and the Sample Delivery Group (SDG) Narrative checking for: pH; cooler temperature; holding time; and other sample conditions.

B. Objective:

The objective is to determine the validity of the analytical results based on the sample condition, and the holding time of the sample from the date of collection to the date of analysis.

C. Criteria:

1. The technical holding time criteria for aqueous/water metal samples is 180 days, preserved (with nitric acid) to $\text{pH} \leq 2$. The addition of nitric acid to adjust the pH is only required for aqueous/water samples.
2. The technical holding time criteria for soil/sediment metal samples is 180 days, based on the technical holding time criteria for aqueous/water samples.
3. Samples shall be maintained at 4°C ($\pm 2^{\circ}\text{C}$) until preparation and analysis.

D. Evaluation:

Technical holding times are established by comparing the sampling date(s) on the TR/COC documentation with the dates of analysis on Form XIII-IN, and the raw data. Information contained in the Complete SDG File (CSF) should also be considered in the determination of holding times. Verify that the analysis dates on the Form XIII-INs and the raw data are identical. Review the SDG Narrative and raw data preparation logs to determine if samples were properly preserved. Review the SDG Narrative to determine if the aqueous/water samples were received in glass containers. If there is an indication that there were problems with the samples, the integrity of the samples may be compromised and professional judgment should be used to evaluate the effect of the problem on the sample results.

E. Action:

NOTE: Apply the action to each sample for which the preservation or holding time criteria was not met.

1. If the pH of aqueous/water metals samples is > 2 at the time of sample receipt, determine if the laboratory adjusted the pH to ≤ 2 at the time of sample receipt. If not, use professional judgment to qualify the samples based on the pH of the sample and the chemistry of the metal(s) of interest. Qualify results that are \geq Method Detection Limit (MDL) as estimated low (J-), and qualify non-detects as unusable (R).
2. If technical holding times are exceeded, use professional judgment to determine the reliability of the data based on the magnitude of the additional time compared to the technical requirement and whether the samples were properly preserved. The expected bias would be low. Qualify results that are \geq MDL as estimated low (J-), and qualify non-detects as unusable (R).
3. Due to limited information concerning holding times for soil/sediment samples, it is left to the discretion of the data reviewer whether to apply 180 day holding time criteria to soil/sediment samples. If it is applied, it must be clearly documented in the Data Review Narrative.
4. When the holding times are exceeded, the reviewer should comment in the Data Review Narrative on any possible consequences for the analytical results.
5. When holding times are grossly exceeded, note this for Contract Laboratory Program Project Officer (CLP PO) action.

Table 10. Technical Holding Time Actions for ICP-MS Analysis

Preservation & Holding Time Results	Action for Samples
Aqueous/water metals samples received with pH > 2 and pH not adjusted	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Metals samples not maintained at 4°C ($\pm 2^\circ\text{C}$)	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Aqueous/water Metals > 180 day	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Soil/sediment Metals > 180 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

ICP-MS Tune Analysis

A. Review Items:

Form XIV-IN, instrument printouts, and raw data.

B. Objective:

The Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) tune serves as an initial demonstration of instrument stability and precision.

C. Criteria:

1. Prior to calibration, the laboratory shall analyze or scan the ICP-MS tuning solution at least five times (5x) consecutively. The tuning solution contains 100 µg/L of Be, Mg, Co, In, and Pb. The solution shall contain all required isotopes of the above elements. The laboratory shall make any adjustments necessary to bring peak width within the instrument manufacturer's specifications and adjust mass resolution to within 0.1 u over the range of 6-210 u.
2. The Percent Relative Standard Deviation (%RSD) of the absolute signals for all analytes in the tuning solution must be < 5%.

D. Evaluation:

1. Verify using the raw data and Form XIV-IN that the appropriate number of analyses or scans of the ICP-MS tuning solution were performed, and that the appropriate analytes were present in the solution.
2. Verify using the raw data and Form XIV-IN that the mass calibration falls within the limits for each isotope of each analyte.
3. Verify using the raw data and Form XIV-IN that the %RSD is < 5% for each isotope of each analyte.
4. Check the raw data to verify that the reported average mass and %RSD on Form XIV-IN was accurately calculated. Recalculate one or more of the average masses and %RSDs for an isotope using the following equations:

$$\text{Mean} = \frac{\sum x}{n}$$

Where,

- x = Mass from analysis
n = Number of analyses

$$\text{Percent Relative Standard Deviation} = \frac{\sigma_{n-1} \times 100}{\bar{x}}$$

Where,

- \bar{x} = Mean
 σ_{n-1} = Standard Deviation

E. Action:

NOTE: For ICP-MS tunes that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

1. If the ICP-MS instrument was not tuned prior to calibration, the sample data should be qualified as unusable (R).

2. If the tuning solution was not analyzed or scanned at least 5x consecutively or the tuning solution does not contain the required analytes spanning the analytical range, the reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should be recorded in the Data Review Narrative and noted for Contract Laboratory Program Project Officer (CLP PO) action.
3. If the resolution of the mass calibration is not within 0.1 u for any isotope in the tuning solution, qualify all analyte results that are \geq Method Detection Limit (MDL) associated with that isotope as estimated (J), and all non-detects associated with that isotope as estimated (UJ). The situation should be recorded in the Data Review Narrative and noted for CLP PO action.
4. If the %RSD exceeds 5% for any isotope in the tuning solution, qualify all sample results that are \geq MDL associated with that tune as estimated (J), and all non-detects associated with that tune as estimated (UJ). The situation should be recorded in the Data Review Narrative and noted for CLP PO action.

Table 11. ICP-MS Tune Actions for ICP-MS Analysis

ICP-MS Tune Results	Action for Samples
Tune not performed	Qualify all results as unusable (R)
Tune not performed properly	Use professional judgment
Resolution of mass calibration not within 0.1 u	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
%RSD > 5%	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)

Calibration

A. Review Items:

Form II-IN (Part A), Form XI-IN, Form XIII-IN, Form XVI-IN, preparation logs, calibration standard logs, instrument logs, instrument printouts, and raw data.

B. Objective:

Method requirements for satisfactory instrument calibration are established to ensure that the instrument is capable of producing acceptable quantitative data for the metals on the Inorganic Target Analyte List (TAL). Initial Calibration Verification (ICV) demonstrates that the instrument is capable of acceptable performance at the beginning of the analytical run. Continuing Calibration Verification (CCV) demonstrates that the initial calibration is still valid by checking the performance of the instrument on a continual basis.

C. Criteria:

1. Initial Calibration

The instruments shall be successfully calibrated each time the instrument is set up and after Continuing Calibration Verification (CCV) failure. The calibration date and time shall be included in the raw data.

- a. A blank and at least five calibration standards shall be used to establish each analytical curve. At least one standard shall be at or below the CRQL. All measurements shall be within the instrument working range. A minimum of three replicate scans are required for standardization and all Quality Control (QC) and sample analyses. The average result of all the multiple scans for the standardization, QC, and sample analyses shall be used. The calibration curve shall be fitted using linear regression or weighted linear regression. The curve may be forced through zero. The curve must have a correlation coefficient of ≥ 0.995 . The calculated percent differences for all of the non-zero standards must be within $\pm 30\%$ of the true value of the standard. The y-intercept of the curve must be less than the CRQL.

2. Initial and Continuing Calibration Verification (ICV and CCV)

The acceptance criteria for the ICVs and CCVs are presented in Table 12:

Table 12. Acceptance Criteria for ICV and CCV Standards

Analytical Method	Inorganic Analytes	ICV/CCV Low Limit (% of True Value)	ICV/CCV High Limit (% of True Value)
ICP-MS	Metals	90	110

a. Initial Calibration Verification (ICV)

- 1) Immediately after each ICP-MS system has been calibrated, the accuracy of the initial calibration must be verified and documented for each target analyte by the analysis of an ICV solution(s). If the ICV Percent Recovery (%R) falls outside of the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and all affected samples reanalyzed.
- 2) Only if the ICV is not available from USEPA, analyses shall be conducted using a certified solution of the analytes from an independent commercial standard source, at a concentration level other than that used for instrument calibration, but within the calibrated range.
- 3) The ICV solution shall be run at each analytical mass used for analysis.

b. Continuing Calibration Verification (CCV)

- 1) To ensure accuracy during the course of each analytical run, the CCV shall be analyzed and reported for each mass used for the analysis of each analyte.
- 2) The CCV standard shall be analyzed at a frequency of every two hours during an analytical run. The CCV standard shall also be analyzed at the beginning of the run, and again after the last analytical sample.
- 3) The analyte concentration(s) in the CCV standard(s) shall be different than the concentration used for the ICV, and at a concentration equivalent to the mid level of their respective calibration curves.
- 4) The same CCV standard solution shall be used throughout the analysis runs for a Sample Delivery Group (SDG).
- 5) The CCV shall be analyzed in the same fashion as an actual sample. If the %R of the CCV was outside of the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and all analytical samples analyzed since the last compliant calibration verification reanalyzed.

D. Evaluation:

1. Verify that the instrument was calibrated each time the instrument was set up, utilizing a blank and at least five calibration standards, one of which was at or below the CRQL.
2. Confirm that the measurements were within the working range, and were the average result of at least three replicate exposures.
3. Verify that the ICV and CCV standards were analyzed for each analyte at the proper frequency and at the appropriate concentration. Verify that acceptable %R results were obtained.
4. Recalculate one or more of the ICV and CCV %Rs using the following equation and verify that the recalculated value agrees with the laboratory-reported values on Form IIA-IN.

$$\%R = \frac{\text{Found (value)}}{\text{True (value)}} \times 100$$

Where,

Found (value) = Concentration (in $\mu\text{g/L}$) of each analyte measured in the analysis of the ICV or CCV solution

True (value) = Concentration (in $\mu\text{g/L}$) of each analyte in the ICV or CCV source

E. Action:

NOTE: For initial calibrations or ICVs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCVs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the QC sample and a subsequent technically acceptable analysis of the QC sample in the analytical run.

1. If the instrument was not calibrated each time the instrument was set up, qualify the data as unusable (R). If the instrument was not calibrated with at least the minimum number of standards, or if the calibration curve does not include standards at required concentrations (e.g., a blank and at least one at or below CRQL), use professional judgment to qualify results that are \geq MDL as estimated (J) or unusable (R), and non-detects as estimated (UJ) or unusable (R).
2. If the correlation coefficient is <0.995 , percent differences are outside the $\pm 30\%$ limit, or the y-intercept \geq CRQL, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).

3. If the ICV or CCV %R falls outside the acceptance windows, use professional judgment to qualify all associated data. If possible, indicate the bias in the review. The following guidelines are recommended:
 - a. If the ICV or CCV %R is $< 75\%$, qualify non-detects as unusable (R). Use professional judgment to qualify all results that are \geq MDL as estimated low (J-) or unusable (R).
 - b. If the ICV or CCV %R falls within the range of 75-89%, qualify sample results that are \geq MDL as estimated low (J-), and qualify non-detects as estimated (UJ).
 - c. If the ICV or CCV %R falls within the range of 111-125%, qualify sample results that are \geq MDL as estimated high (J+).
 - d. If the ICV or CCV %R falls within the range of 111-125%, non-detects should not be qualified.
 - e. If the ICV or CCV %R is $> 125\%$, use professional judgment to qualify results that are \geq MDL as estimated high (J+) or unusable (R). Non-detects should not be qualified.
 - f. If the %R is $> 160\%$, qualify all results that are \geq MDL as unusable (R).
4. If the laboratory failed to provide adequate calibration information, the USEPA Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
5. Note the potential effects on the reported data due to exceeding the calibration criteria in the Data Review Narrative.
6. If calibration criteria are grossly exceeded, note this for Contract Laboratory Program Project Officer (CLP PO) action.

NOTE: For truly critical samples, a further in-depth evaluation of the calibration curve may be warranted to determine if additional qualification is necessary.

Table 13. Calibration Actions for ICP-MS Analysis

Calibration Result	Action for Samples
Calibration not performed	Qualify all results as unusable (R)
Calibration incomplete	Use professional judgment Qualify results that are \geq MDL as estimated (J) or unusable (R) Qualify non-detects as estimated (UJ) or unusable (R)
Correlation coefficient < 0.995 ; %D outside $\pm 30\%$; y-intercept \geq CRQL	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
ICV/CCV %R $< 75\%$	Qualify results that are \geq MDL as estimated low (J-) or unusable (R) Qualify all non-detects as unusable (R)
ICV/CCV %R 75-89%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICV/CCV %R 111-125%	Qualify results that are \geq MDL as estimated (J)
ICV/CCV %R $> 125\%$	Qualify results that are \geq MDL as estimated high (J+) or unusable (R)
ICV/CCV %R $> 160\%$	Qualify results that are \geq MDL as unusable (R)

Blanks

A. Review Items:

Form I-IN, Form III-IN, Form XII-IN, Form XIII-IN, preparation logs, calibration standard logs, instrument logs, and raw data.

B. Objective:

The objective of blank analysis results assessment is to determine the existence and magnitude of contamination resulting from laboratory (or field) activities. The criteria for evaluation of blanks apply to any blank associated with the samples (e.g., method blanks, calibration blanks, field blanks, etc.). If problems with any blank exist, all associated data must be carefully evaluated to determine whether or not there is an inherent variability in the data, or if the problem is an isolated occurrence not affecting other data.

C. Criteria:

1. No contaminants should be found in the blank(s).
2. The Initial Calibration Blank (ICB) shall be analyzed after the analytical standards, but not before analysis of the Initial Calibration Verification (ICV) during the initial calibration of the instrument (see Section III.C.1).
3. A Continuing Calibration Blank (CCB) shall be analyzed at each mass used for the analysis, immediately after every Continuing Calibration Verification (CCV). The CCB shall be analyzed at a frequency of every two hours during the run. The CCB shall be analyzed at the beginning of the run, and again after the last CCV that was analyzed after the last analytical sample of the run. The CCB result (absolute value) shall not exceed the Contract Required Quantitation Limit (CRQL) of each analyte for which analysis is performed.
4. At least one Preparation Blank shall be prepared and analyzed for each matrix, with every Sample Delivery Group (SDG), or with each batch of samples digested, whichever is more frequent. The Preparation Blank consists of reagent water processed through the appropriate sample preparation and analysis procedure.
5. If any analyte concentration in the Preparation Blank is $> \text{CRQL}$, the lowest concentration of that analyte in the associated samples must be ≥ 10 times (10x) the Preparation Blank concentration. Otherwise, all samples associated with that Preparation Blank with the analyte's concentration $< 10x$ the Preparation Blank concentration, and $> \text{CRQL}$, should be redigested and reanalyzed for that analyte (except for an identified field blank). The laboratory is not to correct the sample concentration for the blank value.
6. If the concentration of the Preparation Blank for a certain analyte is $< (-\text{CRQL})$, all samples reported $< 10x$ the CRQL (associated with that analyte in that blank), should be redigested and reanalyzed.

D. Evaluation:

1. Verify that an ICB was analyzed after the calibration, the CCB was analyzed at the proper frequency and location during the run, and Preparation Blanks were prepared and analyzed as appropriate for the SDG (e.g., total number of samples, various types of matrices present, number of digestion batches, etc.).
2. Review the results reported on the Blank Summary (Form III-IN), as well as the raw data for all blanks, and verify that the results were accurately reported.
3. Evaluate all of the associated blanks for the presence of target analytes. Verify that if target analytes were present in a Preparation Blank or if a concentration was $< (-\text{CRQL})$, the affected samples were redigested and reanalyzed. Verify that if target analytes were present in an ICB or a CCB, the analysis was terminated, the problem corrected, the instrument recalibrated, and the preceding 10 analytical samples or all analytical samples analyzed since the last compliant calibration blank reanalyzed.

E. Action:

NOTES: For ICBs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCBs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the CCB and a subsequent technically acceptable analysis of the CCB in the analytical run.

For Preparation Blanks that do not meet the technical criteria, apply the action to all samples prepared in the same preparation batch.

1. If the appropriate blanks were not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank (including Preparation Blanks) reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank (including Preparation Blanks) reported with a negative result, whose value is $<$ (-CRQL), qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. Specific “method” actions include:
 - a. If the absolute value of an ICB or a CCB result $>$ CRQL, the analysis should be terminated. If the analysis was not terminated and the affected samples were not reanalyzed, report non-detect and results that are \geq MDL but \leq CRQL as CRQL-U. For results that are $>$ CRQL but $<$ Blank Result, use professional judgment to qualify the data as unusable or to report the results at the level of the blank with a “U” qualifier. Use professional judgment to qualify results that are $>$ Blank Result. Note this situation for CLP PO action and record it in the Data Review Narrative.
 - b. If the absolute value of the concentration of the Preparation Blank is \leq CRQL, report non-detects and results that are \geq MDL but \leq CRQL as CRQL-U. Use professional judgment to qualify results that are $>$ CRQL.
 - c. If any analyte concentration in the Preparation Blank is $>$ CRQL, the lowest concentration of that analyte in the associated samples must be 10x the Preparation Blank concentration. Otherwise, all samples associated with that blank with concentrations $<$ 10x the Preparation Blank concentration and $>$ CRQL should be redigested and reanalyzed. Raise the CRQL to the concentration found in the Preparation Blank and report those samples that do not require redigestion (that are \geq MDL but \leq CRQL) as CRQL-U. Note for CLP PO action and record in the Data Review Narrative if the laboratory failed to redigest and reanalyze the affected samples. The reviewer shall then use professional judgment to assess the data.

Table 14. Blank Actions for ICP-MS Analysis

Blank Type	Blank Result	Sample Result	Action for Samples
ICB/CCB	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
ICB/CCB	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ Blank Result	Report at level of Blank Result with a "U" or qualify data as unusable (R)
		$>$ Blank Result	Use professional judgment
ICB/CCB	\leq (-MDL), but \geq (-CRQL)	\geq MDL, or non-detect	Use professional judgment
ICB/CCB	$<$ (-CRQL)	$<$ 10x CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)
Preparation Blank	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ 10x the Blank Result	Qualify results as unusable (R) or estimated high (J+)
		\geq 10x the Blank Result	No action
Preparation Blank	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
Preparation Blank	$<$ (-CRQL)	$<$ 10x CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)

Inductively Coupled Plasma - Interference Check Sample (ICP-ICS)

A. Review Items:

Form IVA-IN, Form IVB-IN, Form XIII-IN, instrument printouts, and raw data.

B. Objective:

The Inductively Coupled Plasma-Interference Check Sample (ICP-ICS) verifies the analytical instrument's ability to overcome isobaric interferences typical of those found in samples.

C. Criteria:

1. The ICS consists of two solutions: Solution A and Solution AB. Solution A consists of the interferences, and Solution AB consists of the analytes mixed with the interferences. An ICS analysis consists of analyzing both solutions consecutively, starting with Solution A, for all masses used for each analyte or interferent reported by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS).
2. An ICS must be run at the beginning of each analysis run. The ICS is not to be run prior to the Initial Calibration Verification (ICV), and shall be immediately followed by a Continuing Calibration Verification/Continuing Calibration Blank (CCV/CCB).
3. Results for the ICP-MS analysis of the ICS Solution A shall fall within the control limits of $\pm 2x$ the CRQL, or $\pm 20\%$ of the true value (whichever is greater) for the analytes included in the solution.
4. Results for the ICP-MS analysis of the ICS Solution AB must fall within the control limits of $\pm 2x$ the CRQL, or $\pm 20\%$ of the true value (whichever is greater) for the analytes included in the solution.
5. If the value of an ICS result exceeds $\pm 2x$ the CRQL, or $\pm 20\%$ of true value (whichever is greater) criteria, the analysis shall be terminated, the problem corrected, the instrument recalibrated, the new calibration then reverified, and all analytical samples analyzed since the last compliant ICS reanalyzed.
6. The ICS should be obtained from USEPA, if available, and analyzed according to the instructions supplied with the solutions. If the ICS is not available from USEPA, an independent ICS solution shall be prepared with the interferent and analyte concentrations at the levels specified in the method.

D. Evaluation:

1. Verify using the raw data (ICP instrumental printout) that the ICS was analyzed at the proper frequency and location during the analytical run.
2. Evaluate the ICS raw data for results with an absolute value that is \geq Method Detection Limit (MDL) for those analytes that are not present in the ICS solution.
3. Recalculate using the raw data and the following equation, one or more of the analyte Percent Recoveries (%R), and verify that the recalculated value agrees with the laboratory-reported values on Form IV-IN.

$$\%R = \frac{\text{Found (value)}}{\text{True (value)}} \times 100$$

Where,

Found (value) = Concentration (in $\mu\text{g/L}$) of each analyte interferent measured in the analysis of ICS Solution A or ICS Solution AB

True (value) = Concentration (in $\mu\text{g/L}$) of each analyte or interferent in ICS Solution A or ICS Solution AB

4. If the value of an ICS result exceeds $\pm 2x$ the CRQL, or $\pm 20\%$ of true value (whichever is greater) criteria, and the laboratory failed to terminate the analysis and take the appropriate corrective action, note this for Contract Laboratory Program Project Officer (CLP PO) action and record in the Data Review Narrative. Use professional judgment to assess the data.

E. Action:

NOTE: For an ICS for ICP-MS that does not meet the technical criteria, apply the action to all samples reported from the analytical run.

1. The raw data may not contain results for interferences. In this case, the reviewer shall use professional judgment to qualify the data. If the data does contain results for interferences, the reviewer should apply the following actions to samples with concentrations of interferences that are comparable to, or greater than, their respective levels in the ICS:
 - a. the ICS %R for an analyte is $> 120\%$ (or greater than the true value + $2x$ the CRQL as applicable) and the sample results are non-detects, the data should not be qualified.
 - b. If the ICS %R for an analyte is $> 120\%$ (or greater than the true value + $2x$ the CRQL as applicable) qualify sample results that are \geq MDL as estimated high (J+). If the ICS %R (or true value) grossly exceeds the limits, use professional judgment to qualify the data.
 - c. If the ICS %R for an analyte falls within the range of 50-79% (or less than the true value - $2x$ the CRQL as applicable) qualify sample results that are \geq MDL as estimated low (J-).
 - d. If the ICS recovery for an analyte falls within the range of 50-79% (or less than the true value - $2x$ the CRQL as applicable), the possibility of false negatives exists. Qualify sample non-detects as estimated (UJ).
 - e. If the ICSAB %R for an analyte or interference is $< 50\%$, qualify all sample results that are \geq MDL and all sample non-detects as unusable (R).
2. If results that are \geq MDL are observed for analytes which are not present in the ICS solution, the possibility of false positives exists. An evaluation of the associated sample data for the affected elements should be made. For samples with comparable or higher levels of interferences and with analyte concentrations that approximate those levels found in the ICS, qualify sample results that are \geq MDL as estimated high (J+). Non-detects should not be qualified.
3. If negative results are observed for analytes that are not present in the ICS solution, and their absolute value is \geq MDL, the possibility of false negatives in the samples exists. An evaluation of the associated sample data for the affected analytes should be made. For samples with comparable or higher levels of interferences, qualify non-detects for the affected analytes as estimated (UJ), and results that are \geq MDL but $< 10x$ the absolute value of the negative result as estimated low (J-).
4. If the raw data does not contain results for the interferences, note this in the Data Review Narrative.
5. Actions regarding the interpretation and/or the subsequent qualification of ICP data due to the ICS analytical results can be extremely complex. Use professional judgment to determine the need for the associated sample data to be qualified. The reviewer may need to obtain additional information from the laboratory. All interpretive situations should then be recorded in the Data Review Narrative.
6. If the ICS acceptance criteria are grossly exceeded, note the specifics for CLP PO action.

Table 15. Interference Check Actions for ICP-MS Analysis

Interference Check Sample Results	Action for Samples
ICS %R > 120% (or > true value + 2x the CRQL)	Qualify results that are \geq MDL as estimated high (J+)
ICS %R 50-79% (or < true value - 2x the CRQL)	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICSAB %R < 50%	Qualify all sample data as unusable (R)
Potential false positives in field samples with interferences	Qualify results that are \geq MDL as estimated high (J+)
Potential false negatives in field samples with interferences	Qualify results that are \geq MDL but < 10x(negative value) as estimated low (J-) Qualify non-detects as estimated (UJ)

Laboratory Control Sample (LCS)

A. Review Items:

Form VII-IN, Form XII-IN, preparation logs, instrument printouts, and raw data.

B. Objective:

The Laboratory Control Sample (LCS) serves as a monitor of the overall performance of each step during the analysis, including the sample preparation.

C. Criteria:

1. LCSs shall be analyzed for each analyte utilizing the same sample preparations, analytical methods, and Quality Assurance/Quality Control (QA/QC) procedures as employed for the samples.
 - a. LCS shall be prepared and analyzed for every group of aqueous/water or soil/sediment samples in a Sample Delivery Group (SDG), or with each batch of samples digested, whichever is more frequent. The aqueous/water and soil/sediment LCS shall be spiked such that the final digestate contains each analyte at two times the CRQL for the associated matrix.
 - b. All LCS Percent Recoveries (%R) must fall within the control limits of 70-130%. If the %R for the LCS falls outside of the control limits, the analysis should be terminated, the problem corrected, and the samples prepared with that LCS redigested and reanalyzed.

D. Evaluation:

1. Verify using Form VII-IN, Form XII-IN, and raw data that the appropriate number of required LCSs were prepared and analyzed for the SDG.
 - a. Check the LCSs documentation from the supplier and verify that the LCSs identification and the control limits for it are listed on the Form VII-IN match those of the specific LCSs used for the analysis.
 - b. Evaluate Form VII-IN and verify that all results for each analyte fall within the established control limits.
2. Check the raw data to verify that the %Rs on Form VII-IN were accurately transcribed. Recalculate one or more of the reported %Rs using the following equation:

$$\%R = \frac{\text{Found (value)}}{\text{True (value)}} \times 100$$

Where,

Found (value) = Concentration of each analyte (in $\mu\text{g/L}$ or mg/kg) measured in the analysis of the LCS

True (value) = Concentration of each analyte (in $\mu\text{g/L}$ or mg/kg) in the LCS

3. Verify that the LCS was prepared at the same time as the associated samples using the same procedures.

E. Action:

If the LCS criteria are not met, the laboratory performance and method accuracy are in question. Professional judgment should be used to determine if the data should be qualified or rejected. The following guidance is suggested for qualifying sample data associated with an LCS that does not meet the required criteria.

For an LCS that does not meet the technical criteria, apply the action to all samples in the same preparation batch.

1. LCS:

- a. If the LCS %R falls within the range of 40-69%, qualify sample results that are \geq Method Detection Limit (MDL) as estimated low (J-). If the LCS %R is $> 130\%$, qualify sample results that are \geq MDL as estimated high (J+).
 - b. If the LCS recovery is $> 130\%$ and the sample results are non-detects, the data should not be qualified.
 - c. If the LCS recovery falls within the range of 40-69%, qualify non-detects as estimated (UJ).
 - d. If LCS %R is $< 40\%$, qualify all results that are \geq MDL as estimated low (J-) and all non-detects as unusable (R).
 - e. If the LCS %R is $> 150\%$, qualify all affected data (both detects and non-detects) as unusable (R).
2. If a laboratory fails to analyze an LCS with each SDG, or if a laboratory consistently fails to generate acceptable LCS recoveries, note this for Contract Laboratory Program Project Officer (CLP PO) action
 3. Whenever possible, the potential effects on the data due to out-of-control LCS results should be noted in the Data Review Narrative.

Table 16. LCS Actions for ICP-MS Analysis

LCS Result	Action for Samples
Aqueous/Water and Soil/Sediment %R 40-69%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
Aqueous/Water and Soil/Sediment %R $> 130\%$	Qualify results that are \geq MDL as estimated high (J+)
Aqueous/Water and Soil/Sediment %R $< 40\%$	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Aqueous/Water and Soil/Sediment %R $> 150\%$	Qualify all results as unusable (R)

Duplicate Sample Analysis

A. Review Items:

Cover Page, Form VI-IN, Form XII-IN, instrument printouts, and raw data.

B. Objective:

The objective of duplicate sample analysis is to demonstrate acceptable method precision by the laboratory at the time of analysis. Duplicate analyses are also performed to generate data that determines the long-term precision of the analytical method on various matrices. Non-homogenous samples can impact the apparent method precision. However, aqueous/water samples are generally homogenous and most soil/sediment samples are homogenous within a factor of two or three.

C. Criteria:

1. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for duplicate sample analysis.
2. At least one duplicate sample shall be prepared and analyzed from each group of samples of a similar matrix type (e.g., water or soil) or for each Sample Delivery Group (SDG). Duplicates cannot be averaged for reporting on Form I-IN. Additional duplicate sample analyses may be required by USEPA Regional request. Alternately, the Region may require that a specific sample be used for the duplicate sample analysis.
3. A control limit of 20% for the Relative Percent Difference (RPD) shall be used for original and duplicate sample values \geq five times (5x) the Contract Required Quantitation Limit (CRQL).
4. A control limit of the CRQL shall be used if either the sample or duplicate value is $< 5x$ the CRQL. The absolute value of the control limit (CRQL) shall be entered in the "Control Limit" column on Form VI-IN. If both samples are non-detects, the RPD is not calculated for Form VI-IN.

NOTE: The above control limits are **method requirements** for duplicate samples, regardless of the sample matrix type. However, it should be noted that laboratory variability arising from the sub-sampling of non-homogenous soil samples is a common occurrence. Therefore, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., 35% RPD, 2x the CRQL) to be assessed against duplicate soil samples.

D. Evaluation:

1. Verify from the Cover Page, Form XII-IN, and the raw data that the appropriate number of required duplicate samples were prepared and analyzed for the SDG.
2. Evaluate Form VI-IN and the raw data to verify that all duplicate results for each analyte and method fall within the established control limits.
3. Verify that a field blank or PE sample was not used for duplicate analysis.
4. Check the raw data and recalculate one or more of the RPD values using the following equation to verify that the results were correctly reported on Form VI-IN:

$$RPD = \frac{|S - D|}{(S + D)/2} \times 100$$

Where,

- RPD = Relative Percent Difference
S = Sample Result (original)
D = Duplicate Result

E. Action:

NOTE: For a duplicate sample analysis that does not meet the technical criteria, apply the action to all samples of the same matrix, if the reviewer considers the samples to be sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, when determining similarity, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions]. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar to the duplicate sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for the duplicate, and thus only the field sample used to prepare the duplicate sample should be qualified.

1. If the appropriate number of duplicate samples were not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for Contract Laboratory Program Project Officer (CLP PO) action.
2. If the results from a duplicate analysis for a particular analyte fall outside the appropriate control limits, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
3. If a field blank or PE sample was used for the duplicate sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
4. Note the potential effects on the data due to out-of-control duplicate sample results in the Data Review Narrative.

Table 17. Duplicate Sample Actions for ICP-MS Analysis

Duplicate Sample Results	Action for Samples
Both original sample and duplicate sample $> 5x$ the CRQL and RPD $> 20\%$ *	Qualify those results that are \geq MDL that professional judgment determines to be affected as estimated (J) and non-detects as estimated (UJ)
Original sample or duplicate sample $\leq 5x$ the CRQL (including non-detects) and absolute difference between sample and duplicate $> CRQL$ *	Qualify those results that are \geq MDL that professional judgment determines to be affected as estimated (J) and non-detects as estimated (UJ)

* The above control limits are **method requirements** for duplicate samples, regardless of the sample matrix type. However, it should be noted that laboratory variability arising from the sub-sampling of non-homogenous soil samples is a common occurrence. Therefore, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., 35% RPD, 2x the CRQL) to be assessed against duplicate soil samples.

Spike Sample Analysis

A. Review Items:

Cover Page, Form V-IN (Parts A & B), Form XII-IN, instrument printouts, and raw data.

B. Objective:

The spike sample analysis is designed to provide information about the effect of each sample matrix on the sample preparation procedures and the measurement methodology. Non-homogenous samples can impact the apparent method recovery. However, aqueous/water samples are generally homogenous and most soil/sediment samples are homogenous within a factor of two or three. If the spike is added to the sample before the digestion (e.g., prior to the addition of other reagents), it is referred to as a spiked sample, pre-digestion spike, or Matrix Spike. If the spike is added to the sample after the completion of the digestion procedures, it is referred to as a post-digestion spike, or analytical spike.

C. Criteria:

1. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for spiked sample analysis.
2. At least one spiked sample (pre-digestion) shall be prepared and analyzed from each group of samples with a similar matrix type (e.g., water or soil), or for each Sample Delivery Group (SDG).
3. When the matrix spike recovery falls outside of the control limits and the sample result is < four times (4x) the spike added, a post-digestion spike shall be performed for those analytes that do not meet the specified criteria. An aliquot of the remaining unspiked sample shall be spiked at 2x the indigenous level or 2x the Contract Required Quantitation Limit (CRQL), whichever is greater.
4. The spike Percent Recovery (%R) shall be within the established acceptance limits. However, spike recovery limits do not apply when the sample concentration is $\geq 4x$ the spike added. In such an event, the data shall be reported unflagged, even if the %R does not meet the acceptance criteria.
5. If the spiked sample analysis was performed on the same sample that was chosen for the duplicate sample analysis, spike calculations shall be performed using the results of the sample designated as the "original sample". The average of the duplicate results cannot be used for the purpose of determining %R.

NOTE: The final spike concentrations required for the various target analytes are presented in the methods described in the Statement of Work (SOW).

D. Evaluation:

1. Verify using the Cover Page, Form VA-IN, Form XII-IN, and raw data that the appropriate number of required spiked samples were prepared and analyzed for the SDG.
2. Verify that a field blank or PE sample was not used for the spiked sample analysis.
3. Evaluate Form VA-IN and the raw data to verify that all pre-digestion spiked sample results for each required analyte fall within the established control limits. If not, verify that a post-digestion spike was prepared and analyzed.
4. Recalculate using the raw data, one or more of the %R using the following equation, and verify that the recalculated value agrees with the laboratory-reported values on Forms V (A & B)-IN:

$$\% \text{ Recovery} = \frac{\text{SSR} - \text{SR}}{\text{SA}} \times 100$$

Where,

SSR	=	Spiked Sample Result
SR	=	Sample Result
SA	=	Spike Added

NOTE: When the sample concentration is < Method Detection Limit (MDL), use SR = 0 only for the purposes of calculating the %R. The actual spiked sample results, sample results, and %R (positive or negative) shall still be reported on Forms VA-IN and VB-IN.

E. Action:

NOTE: For a Matrix Spike that does not meet the technical criteria, apply the action to all samples of the same matrix, if the reviewer considers the samples sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions], in determining similarity. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar to the Matrix Spike sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for the Matrix Spike, and thus that only the field sample used to prepare the Matrix Spike sample should be qualified.

1. If the appropriate number of Matrix Spike samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for CLP Project Officer (CLP PO) action.
2. If a field blank or PE sample was used for the spiked sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
3. If the Matrix Spike recovery does not meet the evaluation criteria and a required post-digestion spike was not performed, note this for CLP PO action.
4. If the Matrix Spike %R is < 30%, verify that a post-digestion spike was analyzed if required. If the post-digestion spike %R is < 75% or is not performed, qualify sample results that are \geq MDL as estimated low (J-) and non-detects as unusable (R). If the post-digestion spike %R is \geq 75%, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
5. If the Matrix Spike %R is 30-74% and the sample results are \geq MDL, verify that a post-digestion spike was analyzed, if required. If the %R for the post-digestion spike is also < 75% or is not performed, qualify the affected data as estimated low (J-). If the %R for the post-digestion spike is \geq 75%, qualify the affected data as estimated (J).
6. If the Matrix Spike %R falls within the range of 30-74% and the sample results are non-detects, qualify the affected data as estimated (UJ).
7. If the Matrix Spike %R is > 125% and the reported sample results are non-detects, the sample data should not be qualified.

8. If the Matrix Spike %R is $> 125\%$ and the sample results are \geq MDL, verify that a post-digestion spike was analyzed, if required. If the %R for the post-digestion spike is also $> 125\%$ or is not performed, qualify the affected data as estimated high (J+). If the %R for the post-digestion spike is $\leq 125\%$, qualify the affected data as estimated (J).
9. Note the potential effects on the data due to out-of-control spiked sample results in the Data Review Narrative.

Table 18. Spike Sample Actions for ICP-MS Analysis

Spike Sample Results	Action for Samples
Matrix Spike %R $< 30\%$ Post-digestion spike %R $< 75\%$	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R $< 30\%$ Post-digestion spike %R $\geq 75\%$	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-digestion spike %R $< 75\%$	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-digestion spike %R $\geq 75\%$	Qualify affected results that are \geq MDL as estimated (J) affected non-detects as estimated (UJ)
Matrix Spike %R $> 125\%$ Post-digestion spike %R $> 125\%$	Qualify affected results that are \geq MDL as estimated high (J+)
Matrix Spike %R $> 125\%$ Post-digestion spike %R $\leq 125\%$	Qualify affected results that are \geq MDL as estimated (J)
Matrix Spike %R $< 30\%$ No post-digestion spike performed	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R 30-74% No post-digestion spike performed	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R $> 125\%$ No post-digestion spike performed	Qualify affected results that are \geq MDL as estimated high (J+) Non-detects are not qualified

ICP Serial Dilution

A. Review Items:

Form I-IN, Form VIII-IN, instrument printouts, and raw data.

B. Objective:

The serial dilution of samples quantitated by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) determines whether or not significant physical or chemical interferences exist due to sample matrix.

C. Criteria:

1. An ICP Serial Dilution analysis shall be performed on a sample from each group of samples with a similar matrix type (e.g., water or soil) or for each Sample Delivery Group (SDG), whichever is more frequent.
2. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for the ICP serial dilution analysis.
3. If the analyte concentration is sufficiently high [concentration in the original sample is > 50 times (50x) the Method Detection Limit (MDL)], the Percent Difference (%D) between the original determination and the serial dilution analysis (a five-fold dilution) after correction shall be less than 10.

NOTE: The above criteria are **method requirements** for serial dilution samples, regardless of the sample matrix type. However, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., %D < 15) to be assessed against serial dilution soil samples.

D. Evaluation:

1. Verify that a field blank or PE sample was not used for the serial dilution analysis.
2. Check the raw data and recalculate the %D using the following equation. Verify that the serial dilution analysis results, and the calculated %D results agree with the values reported by the laboratory on Form VIII-IN:

$$\% \text{ Difference} = \frac{|I - S|}{I} \times 100$$

Where,

I = Initial Sample Result

S = Serial Dilution Result

3. Check the raw data for any evidence of positive or negative interference (results from the diluted sample which are significantly different than the original sample), possibly due to high levels of dissolved solids in the sample, ionization effects, etc.

E. Action:

NOTE: For a serial dilution that does not meet the technical criteria, apply the action to all samples of the same matrix if the reviewer considers the samples sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions], in determining similarity. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar

to the serial dilution sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for serial dilution, and thus only the field sample used to prepare the serial dilution sample should be qualified.

1. If the required %D criteria are not met, qualify all affected results that are \geq MDL as estimated (J) and all affected non-detects as estimated (UJ).
2. If evidence of positive or negative interference is found, use professional judgment to qualify the associated sample data. Note the potential effects on the reported data in the Data Review Narrative.
3. It should be noted for CLP Project Officer (CLP PO) action and in the Data Review Narrative if a field blank or PE sample was used for the serial dilution analysis.

Table 19. Serial Dilution Actions for ICP-MS Analysis

Serial Dilution Result	Action for Samples
Sample concentration $>$ 50x MDL and %D $>$ 10*	Qualify affected results that are \geq MDL as estimated (J) Qualify affected non-detects as estimated (UJ)
Interferences present	Use professional judgment

* The above criteria are **method requirements** for serial dilution samples, regardless of the sample matrix type. However, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., %D $<$ 15) to be assessed against serial dilution soil samples.

ICP-MS Internal Standards

A. Review Items:

Form XIII-IN, Form XV-IN, Form XVII-IN, instrument printouts, and raw data.

B. Objective:

The analysis of Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) internal standards determines the existence and magnitude of instrument drift and physical interferences. The criteria for evaluation of internal standard results apply to all analytical and Quality Control (QC) samples analyzed during the run, beginning with the calibration.

C. Criteria:

1. All samples analyzed during a run, with the exception of the ICP-MS tune, shall contain internal standards. A minimum of five internal standards from the following list shall be added to each sample: Li (the Li⁶ isotope); Sc; Y; Rh; Tb; Ho; Lu; and Bi. If the laboratory uses lithium as an internal standard, the laboratory shall use an Li⁶-enriched standard. The laboratory shall monitor the same internal standards throughout the entire analytical run and shall assign each analyte to at least one internal standard.
2. The intensity of the internal standard response in a sample is monitored and compared to the intensity of the response for that internal standard in the calibration blank. The Percent Relative Intensity (%RI) in the sample shall fall within 60-125% of the response in the calibration blank.
3. If the %RI of the response in the sample falls outside of these limits, the laboratory shall reanalyze the original sample at a two-fold dilution with internal standard added.

D. Evaluation:

1. Verify using Forms XV-IN, XVII-IN, and the raw data that a minimum of five internal standards from the specified list were used for the analysis, that the same internal standards were monitored for the entire run, and that each analyte was associated to at least one internal standard.
2. Verify using Form XV-IN and the raw data that these internal standards were added to each sample in the run, including calibrations, samples, and QC samples (except tune).
3. Verify using Form XV-IN that the %RI between an internal standard in a sample and the internal standard in the calibration blank was reported for each sample.
4. Verify using Form XIII-IN, Form XV-IN, and the raw data that if the %RI for a sample was outside the limits (60-125%), the sample was reanalyzed of a 2x dilution with internal standard added.

E. Action:

NOTE: Apply the action to the affected analytes for each sample that does not meet the internal standard criteria.

1. If no internal standards were analyzed with the run, the sample data should be qualified as unusable (R). Record this in the Data Review Narrative and note for CLP Project Officer (CLP PO) action.
2. If less than five of the required internal standards were analyzed with the run, or a target analyte(s) is (are) not associated to an internal standard, the sample data, or analyte data not associated to an internal standard should be qualified as unusable (R). Record this in the Data Review Narrative and note for CLP PO action.
3. If the %RIs for all internal standards in a sample is within the 60-125% limit, the sample data should not be qualified.
4. If the %RI for an internal standard in a sample is not within the 60-125% limit, qualify the data for those analytes associated with the internal standard(s) outside the limit as follows:

- a. If the sample was reanalyzed at a two-fold dilution with internal standard %RI within the limits, report the result of the diluted analysis without qualification. If the %RI of the diluted analysis was not within the 60-125% limit, report the results of the original undiluted analyses and qualify the data for all analytes that are \geq Method Detection Limit (MDL) in the sample associated with the internal standard as estimated (J), and non-detected analytes associated with the internal standard as estimated (UJ).
- b. If the sample was not reanalyzed at a two-fold dilution, the reviewer should use professional judgment to determine the reliability of the data. The reviewer may determine that the results are estimated (J) or unusable (R).

Table 20. Internal Standard Actions for ICP-MS Analysis

Internal Standard Results	Action for Samples
No internal standards	Qualify all results as unusable (R)
< 5 of the required internal standards	Qualify all analyte results not as unusable (R)
Target analyte not associated with internal standard	Qualify all analyte results not associated with internal standard as unusable (R)
%RI < 60% or > 125%, and original sample reanalyzed at 2-fold dilution	If %RI of diluted sample analysis 60-125%, do not qualify the data If the %RI of the diluted sample analysis is outside the 60-125% limit, qualify results that are \geq MDL as estimated (J) and qualify non-detects as estimated (UJ)
Original sample not reanalyzed at 2-fold dilution	Use professional judgment Qualify sample results as estimated (J) or unusable (R)

Regional Quality Assurance (QA) and Quality Control (QC)**A. Review Items:**

Form I-IN, instrument printouts, and raw data.

B. Objective:

Regional QA/QC samples refer to any QA and/or QC samples initiated by the Region, including field duplicate samples, Performance Evaluation (PE) samples, blind spikes, and blind blanks. The use of these QA/QC samples is highly recommended (e.g., the use of field duplicate samples can provide information on sampling precision and sample homogeneity).

C. Criteria:

Criteria are determined by each Region.

D. Evaluation:

Evaluation procedures must follow the Region's Standard Operating Procedure (SOP) for data review. Each Region will handle the evaluation of PE samples on an individual basis. Compare results for PE samples to the acceptance criteria for the specific PE samples if possible.

Calculate the Relative Percent Difference (RPD) between field duplicates and provide this information in the Data Review Narrative.

E. Action:

Any action must be in accordance with Regional specifications and criteria for acceptable PE sample results. Note any unacceptable PE sample results for Contract Laboratory Program Project Officer (CLP PO) action.

Overall Assessment

A. Review Items:

Entire sample data package, data review results, preparation logs, calibration standard logs, instrument logs, instrument printouts, and raw data (including any confirmation data).

B. Objective:

The objective is to ensure that the reported sample quantitation results are accurate. It is appropriate for the data reviewer to make professional judgments and express concerns, as well as to comment on the validity of the overall data for a Case. This is particularly appropriate when there are several Quality Control (QC) criteria that are outside of the specification parameters. The additive nature of QC factors that fall outside of specification parameters is difficult to assess in an objective manner, but the reviewer has a responsibility to inform the user of data quality and data limitations to assist that user in avoiding inappropriate use of the data, while not precluding any consideration of the data at all. If qualifiers other than those used in this document are necessary to describe or qualify the data, it is necessary to thoroughly document/explain the additional qualifiers used. The data reviewer would be greatly assisted in this endeavor if the acceptance or performance criteria were provided. The Inorganic Review Summary (see Appendix B) and supplementary documentation must be included with the review.

C. Criteria:

1. Review all available materials to assess the overall quality of the data, keeping in mind the additive nature of analytical problems.
2. Reported analyte concentrations must be quantitated according to the appropriate analytical method, as listed in the method.

D. Evaluation:

Examine the raw data to verify that the correct calculation of the sample results was reported by the laboratory. Digestion logs, instrument printouts, etc., should be compared to the reported sample results recorded on the appropriate Inorganic Summary Forms (Form I-IN through Form XV-IN).

1. Evaluate any technical problems not previously addressed.
2. Examine the raw data for any anomalies (e.g., baseline shifts, negative response, mass dependent drift, omissions, illegibility, etc.).
3. Verify appropriate methods and volumes were used in preparing the samples for analysis. If reduced volumes were used, verify that the laboratory had received Contract Laboratory Program Project Officer (CLP PO) approval for the use of the reduced volume.
4. Verify that there are no transcription or reduction errors [e.g., dilutions, Percent Solids (%S), sample weights, etc.] on one or more samples.
5. Verify that results fall within the calibrated range(s) of the Inductively Coupled Plasma (ICP) instrument(s) (Form XI).
6. If appropriate information is available, the reviewer may assess the usability of the data to assist the data user in avoiding inappropriate use of the data. Review all available information, including the Quality Assurance Project Plan (QAPP), focusing specifically on the acceptance or performance criteria, the Standard Operating Procedure(s) (SOPs), and communication with the user concerning the intended use and desired quality of these data.

E. Action:

1. Use professional judgment to determine if there is any need to qualify data which were not qualified based on the QC criteria previously discussed.

2. Write a brief Data Review Narrative to give the user an indication of the analytical limitations of the data. Note any discrepancies between the data and the SDG Narrative for CLP PO action. If sufficient information on the intended use and required quality of the data is available, the reviewer should include an assessment of the data usability within the given context.
3. If any discrepancies are found, the laboratory may be contacted by the Region's designated representative to obtain additional information for resolution. If a discrepancy remains unresolved, the reviewer may determine that qualification of the data is warranted.

Calculations for ICP-MS**Aqueous/Water Sample Concentration by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS):**

The concentrations determined in the digestate are to be reported in units of µg/L:

$$\text{Concentration (ug/L)} = C \times \frac{V_f}{V} \times DF$$

Where,

- C = Instrument value in µg/L (The average of all replicate integrations).
 V_f = Final digestion volume (mL)
 V = Initial Aliquot Amount (mL)
 DF = Dilution Factor

Soil/Sediment Sample Concentration by ICP-MS:

The concentrations determined in the digestate are to be reported on the basis of the dry weight of the sample, in units of mg/kg:

$$\text{Concentration (dry wt.)(mg/kg)} = C \times \frac{V_f}{W \times S} \times DF / 1000$$

Where,

- C = Instrument value in µg/L (The average of all replicate integrations).
 V_f = Final digestion volume (mL)
 W = Initial aliquot amount (g)
 S = % Solids/100 (see Exhibit D - Introduction to Analytical Methods, Section 1.6)
 DF = Dilution Factor

Adjusted Method Detection Limit (MDL)/Adjusted Contract Required Quantitation Limit (CRQL) Calculation:

To calculate the adjusted MDL or adjusted CRQL for aqueous/water samples, substitute the value of the MDL (µg/L) or CRQL (µg/L) into the “C” term in the equation above.

Calculate the adjusted MDL or adjusted CRQL for soil/sediment samples as follows:

$$\text{Adjusted Concentration (mg/kg)} = C \times \frac{W_M}{W \times S} \times \frac{V_f}{V_M} \times DF$$

Where,

- C = MDL or CRQL (mg/kg)
 W_M = Minimum method required aliquot amount (g) (1.00g or 0.50g)
 W = Initial aliquot amount (g)
 V_M = Method required final sample digestion volume (mL) (100 mL)
 V_f = Final digestion volume (mL)
 S = % Solids/100 (see Exhibit D - Introduction to Analytical Methods, Section 1.6)
 DF = Dilution Factor

MERCURY DATA REVIEW

The inorganic data requirements for mercury data review to be reviewed during validation are listed below:

I.	Preservation and Holding Times	64
II.	Calibration.....	66
III.	Blanks.....	69
IV.	Duplicate Sample Analysis.....	72
V.	Spike Sample Analysis.....	74
VI.	Regional Quality Assurance (QA) and Quality Control (QC).....	76
VII.	Overall Assessment	77
	Calculations for Mercury	79

I. Preservation and Holding Times

A. Review Items:

Form IA-IN, Form IB-IN, Form XII-IN, Form XIII-IN, Traffic Report/Chain of Custody (TR/COC) documentation, Form DC-1, raw data, and the Sample Delivery Group (SDG) Narrative checking for: pH; cooler temperature; holding time; and other sample conditions.

B. Objective:

The objective is to ascertain the validity of the analytical results based on the sample condition, and the holding time of the sample from the date of collection to the date of analysis.

C. Criteria:

1. The technical holding time criteria for aqueous/water mercury samples is 28 days; preserved (with nitric acid) to $\text{pH} \leq 2$. The addition of nitric acid to adjust the pH is only required for aqueous/water samples.
2. The technical holding time criteria for soil/sediment mercury samples is 28 days, based on the technical holding time criteria for aqueous/water samples.
3. Mercury samples shall be maintained at 4°C ($\pm 2^\circ\text{C}$) until preparation and analysis to allow for re-preparation.
4. Samples and standards shall be analyzed with 48 hours of preparation.

D. Evaluation:

Technical holding times are established by comparing the sampling date(s) on the TR/COC documentation with the dates of analysis on Form XIII-IN, and the raw data. Information contained in the Complete SDG File (CSF) should also be considered in the determination of holding times. Verify that the analysis dates on the Form XIII and the raw data are identical. Review the SDG Narrative and raw data preparation logs to determine if samples were properly preserved. If there is an indication that there were problems with the samples, the integrity of the samples may be compromised and professional judgment should be used to evaluate the effect of the problem on the sample results.

E. Action:

NOTE: Apply the action to each sample for which the preservation or holding time criteria was not met.

1. If the pH of aqueous/water metals samples is > 2 at the time of sample receipt, determine if the laboratory adjusted the pH to ≤ 2 at the time of sample receipt. If not, use professional judgment to qualify the samples based on the pH of the sample and the chemistry of the metal(s) of interest. Qualify results that are \geq Method Detection Limit (MDL) as estimated low (J-), and qualify non-detects as unusable (R).
2. If technical holding times are exceeded, use professional judgment to determine the reliability of the data based on the magnitude of the additional time compared to the technical requirement and whether the samples were properly preserved. The expected bias would be low. Qualify results that are \geq MDL as estimated low (J-), and qualify non-detects as unusable (R).
3. Due to limited information concerning holding times for soil/sediment samples, it is left to the discretion of the data reviewer whether to apply aqueous/water holding time criteria to soil/sediment samples. If they are applied, it must be clearly documented in the Data Review Narrative.
4. When the holding times are exceeded, the reviewer should comment in the Data Review Narrative on any possible consequences for the analytical results.
5. When holding times are grossly exceeded, note it for Contract Laboratory Program Project Officer (CLP PO) action.

6. When shipping or storage temperatures grossly exceed the requirements, the loss of volatile mercury compounds or metallic mercury is possible. The expected bias would be low. Use professional judgment to qualify the samples and note for CLP PO action.

Table 21. Technical Holding Time Actions for Mercury Analysis

Preservation & Holding Time Results	Action for Samples
Aqueous/water metals samples received with pH > 2 and pH not adjusted	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Samples not maintained at 4 °C (± 2 °C)	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding time exceeded: Aqueous/water Samples > 28 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Soil/sediment Metals > 28 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

Calibration

A. Review Items:

Form II-IN (Part A), Form XI-IN, Form XIII-IN, Form XVI-IN, preparation logs, calibration standard logs, instrument logs, instrument printouts, and raw data.

B. Objective:

Method requirements for satisfactory instrument calibration are established to ensure that the instrument is capable of producing acceptable quantitative data for mercury. Initial Calibration Verification (ICV) demonstrates that the instrument is capable of acceptable performance at the beginning of the analytical run. Continuing Calibration Verification (CCV) demonstrates that the initial calibration is still valid by checking the performance of the instrument on a continuing basis.

C. Criteria:

1. Initial Calibration

The instruments shall be successfully calibrated daily (or once every 24 hours), and each time the instrument is set up. The calibration date and time shall be included in the raw data. The calibration curve shall be prepared by the same method used to prepare the samples for analysis. The curve shall be prepared with the samples that will be analyzed using this calibration curve.

a. Cold Vapor Mercury Analysis

- 1) A blank and at least five calibration standards shall be employed to establish the analytical curve. At least one of the calibration standards shall be at or below the Contract Required Quantitation Limit (CRQL). The calibration curve shall be fitted using linear regression or weighted linear regression. The curve may be forced through zero. The calibration curves for mercury shall possess a correlation coefficient of ≥ 0.995 to ensure the linearity over the calibrated range. The percent differences calculated for all of the non-zero standards must fall within $\pm 30\%$ of the true value of the standard. The y-intercept of the curve must be less than the CRQL. All sample results shall be reported from an analysis within the calibrated range.

2. Initial and Continuing Calibration Verification (ICV and CCV)

The acceptance criteria for the ICVs and CCVs are presented in Table 22. These standards shall be prepared by the same method used to prepare the samples for analysis.

Table 22. Acceptance Criteria for ICVs and CCVs

Analytical Method	Inorganic Analyte	ICV/CCV Low Limit (% of True Value)	ICV/CCV High Limit (% of True Value)
Cold Vapor AA	Mercury	85	115

a. Initial Calibration Verification (ICV)

- 1) Immediately after each Atomic Absorption (AA) system has been calibrated, the accuracy of the initial calibration must be verified and documented for mercury by the analysis of an ICV solution(s). If the ICV %R falls outside of the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and all affected samples reanalyzed.
- 2) If the ICV is not available from USEPA, or where a certified solution of the analyte is not available from any source, analyses shall be conducted on an independent standard at a concentration level other than that used for instrument calibration, but within the calibrated range.

b. Continuing Calibration Verification (CCV)

- 1) To ensure accuracy during the course of each analytical run, the CCV shall be analyzed and reported.
- 2) The CCV standard shall be analyzed at a frequency of every hour during an analytical run. The CCV standard shall also be analyzed at the beginning of the run, and again after the last analytical sample.
- 3) The analyte concentration in the CCV standard shall be different than the concentration used for the ICV, and shall be at the mid level of the calibration curve.
- 4) The same CCV standard solution shall be used throughout the analysis runs for a Sample Delivery Group (SDG).
- 5) The CCV shall be analyzed in the same fashion as an actual sample. If the %R of the CCV was outside of the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and all analytical samples analyzed since the last compliant CCV reanalyzed.

D. Evaluation:

1. Verify that the instrument was calibrated daily (once every 24 hours) and each time the instrument was set up, utilizing a blank and at least five calibration standards. Confirm that at least one of the calibration standards was analyzed at or below the CRQL. Confirm that calibration standards and samples were prepared at the same time.
2. Confirm that the measurements were within the documented working range of the calibration standards.
3. Verify that the ICV and CCV standards were analyzed for mercury at the proper frequency and at the appropriate concentration. Verify that acceptable %R results were obtained.
4. Recalculate one or more of the ICV or CCV %R using the following equation and verify that the recalculated value agrees with the laboratory-reported values on Form IIA-IN.

$$\%R = \frac{\text{Found (value)}}{\text{True (value)}} \times 100$$

Where,

- Found (value) = Concentration (in µg/L) of mercury measured in the analysis of the ICV or CCV solution
- True (value) = Concentration (in µg/L) of mercury in the ICV or CCV source

E. Action:

NOTES: For initial calibrations or ICVs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCVs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the QC sample and a subsequent technically acceptable analysis of the QC sample in the analytical run.

1. If the instrument was not calibrated daily and each time the instrument was set up, qualify the data as unusable (R). If the instrument was not calibrated with at least the minimum number of standards, or if the calibration curve does not include standards at required concentrations (e.g., a blank, and at least one standard at or below the CRQL), or if the instrument was not calibrated with standards prepared at the same time as the samples, use professional judgment to qualify results that are \geq Method Detection Limit (MDL) as estimated (J) or unusable (R), and non-detects as estimated (UJ) or unusable (R).

2. If the correlation coefficient is < 0.995 , percent differences are outside the $\pm 30\%$ limit, or the y-intercept is $> \text{CRQL}$, qualify sample results that are $\geq \text{MDL}$ as estimated (J), and non-detects as estimated (UJ). Depending on the degree of the deviation from linearity, further qualification of the data may be required depending on the professional judgment of the reviewer [e.g., unusable data (R)].
3. If the ICV or CCV %R falls outside the acceptance windows, use professional judgment to qualify all associated data. If possible, indicate the bias in the review. The following guidelines are recommended:
 - a. If the ICV or CCV %R is $< 70\%$, qualify non-detects as unusable (R). Use professional judgment to qualify all results that are $\geq \text{MDL}$ as estimated low (J-) or unusable (R).
 - b. If the ICV or CCV %R falls within the range of 70-84%, qualify sample results that are $\geq \text{MDL}$ as estimated low (J-) and qualify non-detects as estimated (UJ).
 - c. If the ICV or CCV %R falls within the range of 116-130%, qualify sample results that are $\geq \text{MDL}$ as estimated high (J+).
 - d. If the ICV or CCV %R falls within the range of 116-130%, non-detects should not be qualified.
 - e. If the ICV or CCV %R is $> 130\%$, use professional judgment to qualify results that are $\geq \text{MDL}$ as estimated high (J+) or unusable (R). Non-detects should not be qualified.
 - f. If the %R is $> 165\%$, qualify all results that are $\geq \text{MDL}$ as unusable (R).
4. If the laboratory failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
5. Note the potential effects on the reported data due to exceeding the calibration criteria in the Data Review Narrative.
6. If calibration criteria are grossly exceeded, note this for CLP Project Officer (CLP PO) action.

NOTE: For truly critical samples, a further in-depth evaluation of the calibration curve may be warranted to determine if additional qualification is necessary.

Table 23. Calibration Actions for Mercury Analysis

Calibration Result	Action for Samples
Calibration not performed	Qualify all results as unusable (R)
Calibration incomplete	Use professional judgment Qualify results that are $\geq \text{MDL}$ as estimated (J) or unusable (R) Qualify non-detects as estimated (UJ) or unusable (R)
Correlation coefficient < 0.995 , %D outside $\pm 30\%$, y-intercept $\geq \text{CRQL}$	Qualify results that are $\geq \text{MDL}$ as estimated (J) Qualify non-detects as estimated (UJ)
ICV/CCV %R $< 70\%$	Qualify results that are $\geq \text{MDL}$ as estimated low (J-) or unusable (R) Qualify all non-detects as unusable (R)
ICV/CCV %R 70-84%	Qualify results that are $\geq \text{MDL}$ as estimated low (J-) Qualify non-detects as estimated (UJ)
ICV/CCV %R 116-130%	Qualify results that are $\geq \text{MDL}$ as estimated (J)
ICV/CCV %R $> 130\%$	Qualify results that are $\geq \text{MDL}$ as estimated high (J+) or unusable (R)
ICV/CCV %R $> 165\%$	Qualify results that are $\geq \text{MDL}$ as unusable (R)

Blanks

A. Review Items:

Form I-IN, Form III-IN, Form XII-IN, Form XIII-IN, preparation logs, calibration standard logs, instrument logs, and raw data.

B. Objective:

The objective of blank analysis results assessment is to determine the existence and magnitude of contamination resulting from laboratory (or field) activities. The criteria for evaluation of blanks apply to any blank associated with the samples (e.g., method blanks, calibration blanks, field blanks, etc.). If problems with any blank exist, all associated data must be carefully evaluated to determine whether or not there is an inherent variability in the data, or if the problem is an isolated occurrence not affecting other data.

C. Criteria:

1. No contaminants should be found in the blank(s).
2. The Initial Calibration Blank (ICB) shall be analyzed after the analytical standards, but not before analysis of the Initial Calibration Verification (ICV) during the initial calibration of the instrument (see Section II.C.1). The ICB shall be prepared by the same method used to prepare the samples for analysis.
3. A Continuing Calibration Blank (CCB) shall be analyzed immediately after every Continuing Calibration Verification (CCV). The CCB shall be prepared by the same method used to prepare the samples for analysis. The CCB shall be analyzed at a frequency of every hour during the run. The CCB shall be analyzed at the beginning of the run, and again after the last CCV that was analyzed after the last analytical sample of the run. The CCB result (absolute value) shall not exceed the Contract Required Quantitation Limit (CRQL) for mercury.
4. At least one Preparation Blank shall be prepared and analyzed for each matrix, with every Sample Delivery Group (SDG), or with each batch of samples digested, whichever is more frequent. The Preparation Blank consists of reagent water processed through the appropriate sample preparation and analysis procedure.
5. If the mercury concentration in the Preparation Blank is $> \text{CRQL}$, the lowest concentration of mercury in the associated samples must be ≥ 10 times (10x) the Preparation Blank concentration. Otherwise, all samples associated with that Preparation Blank with a mercury concentration $< 10x$ the Preparation Blank concentration, and $> \text{CRQL}$, should be redigested and reanalyzed (except for an identified field blank). The laboratory is not to correct the sample concentration for the blank value.
6. If the concentration of the Preparation Blank for mercury is $< (-\text{CRQL})$, all samples reported $< 10x$ the CRQL (associated with that analyte in that blank), should be redigested and reanalyzed.

D. Evaluation:

1. Verify that an ICB was analyzed after the calibration, the CCB was analyzed at the proper frequency and location during the run, and Preparation Blanks are prepared and analyzed as appropriate for the SDG (e.g., total number of samples, various types of matrices present, number of digestion batches, etc.).
2. Review the results reported on the Blank Summary (Form III-IN), as well as the raw data for all blanks, and verify that the results are accurately reported.
3. Evaluate all of the associated blanks for the presence of mercury. Verify that if mercury was present in a Preparation Blank or if a concentration was $< (-\text{CRQL})$, the affected samples were redigested and reanalyzed. Verify that if mercury was present in an ICB or a CCB, the analysis was terminated, the problem corrected, the instrument recalibrated, and the preceding 10 analytical samples or all analytical samples analyzed since the last compliant calibration blank reanalyzed.

E. Action:

NOTES: For ICBs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCBs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the CCB and a subsequent technically acceptable analysis of the CCB in the analytical run.

For Preparation Blanks that do not meet the technical criteria, apply the action to all samples prepared in the same preparation batch.

1. If the appropriate blanks are not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank (including Preparation Blanks) reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank (including Preparation Blanks) reported with a negative result, whose value is $<$ (-CRQL), qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. Specific “method” actions include:
 - a. If the absolute value of an ICB or a CCB result is $>$ CRQL, the analysis should be terminated. If the analysis was not terminated and the affected samples are not reanalyzed, report non-detects and results that are \geq MDL but \leq CRQL as CRQL-U. For results that are $>$ CRQL but $<$ Blank Result, use professional judgment to qualify the data as unusable (R), or to report the results at the level of the blank with a “U” qualifier. Use professional judgment to qualify results that are $>$ Blank Result. Note this situation for CLP PO action and record it in the Data Review Narrative.
 - b. If the absolute value of the concentration of the Preparation Blank is \leq CRQL, report non-detect and results that are \geq MDL but \leq CRQL as CRQL-U. Use professional judgment to qualify results that are $>$ CRQL.
 - c. If the mercury concentration in the Preparation Blank is $>$ CRQL, the lowest concentration of mercury in the associated samples must be 10x the Preparation Blank concentration. Otherwise, all samples associated with that blank with concentrations $<$ 10x the Preparation Blank concentration and $>$ CRQL should be redigested and reanalyzed. Raise the CRQL to the concentration found in the Preparation Blank and report those samples that do not require redigestion (that are \geq MDL but \leq CRQL) as CRQL-U. Note for CLP PO action and record in the Data Review Narrative if the laboratory failed to redigest and reanalyze the affected samples. The reviewer shall then use professional judgment to assess the data.

Table 24. Blank Actions for Mercury Analysis

Blank Type	Blank Result	Sample Result	Action for Samples
ICB/CCB	Absolute value is \geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
ICB/CCB	Absolute value is $>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ Blank Result	Report at level of Blank Result with a "U" or qualify data as unusable (R)
		$>$ Blank Result	Use professional judgment
ICB/CCB	\leq (-MDL), but \geq (-CRQL)	\geq MDL, or non-detect	Use professional judgment
ICB/CCB	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)
Preparation Blank	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ 10x the Blank Result	Qualify results as unusable (R) or estimated high (J+)
		\geq 10x the Blank Result	No action
Preparation Blank	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL with a "U"
		$>$ CRQL	Use professional judgment
Preparation Blank	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)

Duplicate Sample Analysis

A. Review Items:

Cover Page, Form VI-IN, Form XII-IN, instrument printouts, and raw data.

B. Objective:

The objective of duplicate sample analysis is to demonstrate acceptable method precision by the laboratory at the time of analysis. Duplicate analyses are also performed to generate data that determines the long-term precision of the analytical method on various matrices. Non-homogenous samples can impact the apparent method precision. However, aqueous/water samples are generally homogenous and most soil/sediment samples are homogenous within a factor of two or three.

C. Criteria:

1. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for duplicate sample analysis.
2. At least one duplicate sample shall be prepared and analyzed from each group of samples of a similar matrix type (e.g., water or soil) or for each Sample Delivery Group (SDG). Duplicates cannot be averaged for reporting on Form I-IN. Additional duplicate sample analyses may be required by USEPA Regional request. Alternately, the Region may require that a specific sample be used for the duplicate sample analysis.
3. A control limit of 20% for the Relative Percent Difference (RPD) shall be used for original and duplicate sample values \geq five times (5x) the Contract Required Quantitation Limit (CRQL).
4. A control limit of the CRQL shall be used if either the sample or duplicate value is $< 5x$ the CRQL. The absolute value of the control limit (CRQL) shall be entered in the "Control Limit" column on Form VI-IN. If both samples are non-detects, the RPD is not calculated for Form VI-IN.

NOTE: The above control limits are **method requirements** for duplicate samples, regardless of the sample matrix type. However, it should be noted that laboratory variability arising from the sub-sampling of non-homogenous soil samples is a common occurrence. Therefore, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., 35% RPD, 2x the CRQL) to be assessed against duplicate soil samples.

D. Evaluation:

1. Verify from the Cover Page, Form XII-IN, and the raw data that the appropriate number of required duplicate samples were prepared and analyzed for the SDG.
2. Evaluate Form VI-IN and the raw data to verify that all mercury duplicate results for each method fall within the established control limits.
3. Verify that a field blank or PE sample was not used for duplicate analysis.
4. Check the raw data and recalculate one or more of the RPD values using the following equation to verify that the results were correctly reported on Form VI-IN:

$$RPD = \frac{|S - D|}{(S + D)/2} \times 100$$

Where,

- RPD = Relative Percent Difference
S = Sample Result (original)
D = Duplicate Result

E. Action:

NOTE: For a duplicate sample analysis that does not meet the technical criteria, apply the action to all samples of the same matrix, if the reviewer considers the samples sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions], in determining similarity. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar to the duplicate sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for the duplicate, and thus that only the field sample used to prepare the duplicate sample should be qualified.

1. If the appropriate number of duplicate samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for Contract Laboratory Program Project Officer (CLP PO) action.
2. If the results from a duplicate analysis for mercury fall outside the appropriate control limits, qualify sample results that are \geq Method Detection Limit (MDL) as estimated (J) and non-detects as estimated (UJ).
3. If a field blank or PE sample was used for the duplicate sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
4. Note the potential effects on the data due to out-of-control duplicate sample results in the Data Review Narrative.

Table 25. Duplicate Sample Actions for Mercury Analysis

Duplicate Sample Results	Action for Samples
Both original sample and duplicate sample $> 5x$ the CRQL and RPD $> 20\%$ *	Qualify those results that are \geq MDL that professional judgment determines to be affected as estimated (J) and non-detects as estimated (UJ)
Original sample or duplicate sample $\leq 5x$ the CRQL (including non-detects) and absolute difference between sample and duplicate $> CRQL$ *	Qualify those results that are \geq MDL that professional judgment determines to be affected as estimated (J) and non-detects as estimated (UJ)

- * The above control limits are **method requirements** for duplicate samples, regardless of the sample matrix type. However, it should be noted that laboratory variability arising from the sub-sampling of non-homogenous soil samples is a common occurrence. Therefore, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., 35% RPD, 2x the CRQL) to be assessed against duplicate soil samples.

Spike Sample Analysis

A. Review Items:

Cover Page, Form V-IN (Parts A & B), Form XII-IN, instrument printouts, and raw data.

B. Objective:

The spiked sample analysis is designed to provide information about the effect of each sample matrix on the sample preparation procedures and the measurement methodology. Non-homogenous samples can impact the apparent method recovery. However, aqueous/water samples are generally homogenous and most soil/sediment samples are homogenous within a factor of two or three. If the spike is added to the sample before the digestion (e.g., prior to the addition of other reagents), it is referred to as a spiked sample, pre-digestion spike, or Matrix Spike.

C. Criteria:

1. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for spiked sample analysis.
2. At least one spiked sample (pre-digestion) shall be prepared and analyzed from each group of samples with a similar matrix type (e.g., water or soil), or for each Sample Delivery Group (SDG).
3. The spike Percent Recovery (%R) shall be within the established acceptance limits. However, spike recovery limits do not apply when the sample concentration is \geq four times (4x) the spike added. In such an event, the data shall be reported unflagged, even if the %R does not meet the acceptance criteria.
4. If the spiked sample analysis was performed on the same sample that was chosen for the duplicate sample analysis, spike calculations shall be performed using the results of the sample designated as the "original sample". The average of the duplicate results cannot be used for the purpose of determining %R.

NOTE: The final spike concentrations required for mercury are presented in the method described in the Statement of Work (SOW).

D. Evaluation:

1. Verify using the Cover Page, Form VA-IN, Form XII-IN, and raw data that the appropriate number of required spiked samples were prepared and analyzed for the SDG.
2. Verify that a field blank or PE sample was not used for the spiked sample analysis.
3. Evaluate Form VA-IN and the raw data to verify that all Matrix Spike sample results for mercury fall within the established control limits.
4. Recalculate using the raw data, one or more of the %R using the following equation, and verify that the recalculated value agrees with the laboratory-reported values on Forms V (A & B)-IN:

$$\% \text{Recovery} = \frac{\text{SSR} - \text{SR}}{\text{SA}} \times 100$$

Where,

SSR = Spiked Sample Result

SR = Sample Result

SA = Spike Added

NOTE: When the sample concentration is $<$ Method Detection Limit (MDL), use SR = 0 only for the purposes of calculating the %R. The actual spiked sample results, sample results, and %R (positive or negative) shall still be reported on Forms VA-IN and VB-IN.

E. Action:

NOTE: For a Matrix Spike that does not meet the technical criteria, apply the action to all samples of the same matrix, if the reviewer considers the samples sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions], in determining similarity. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar to the Matrix Spike sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for the Matrix Spike, and thus that only the field sample used to prepare the Matrix Spike sample should be qualified.

1. If the appropriate number of Matrix Spike samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for CLP Project Officer (CLP PO) action.
2. If a field blank or PE sample was used for the spiked sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
3. If the Matrix Spike %R is < 30%, qualify affected results that are \geq MDL as estimated low (J-). Qualify affected non-detects as unusable (R).
4. If the Matrix Spike %R falls within the range of 30-74% and the sample results are \geq MDL, qualify the affected data as estimated low (J-).
5. If the Matrix Spike %R falls within the range of 30-74% and the sample results are non-detects, qualify the affected data as estimated (UJ).
6. If the Matrix Spike %R is > 125% and the reported sample results are non-detects, the sample data should not be qualified.
7. If the Matrix Spike %R is > 125% and the sample results are \geq MDL, qualify the affected data as estimated high (J+).
8. Note the potential effects on the data due to out-of-control spiked sample results in the Data Review Narrative.

Table 26. Spike Sample Actions for Mercury Analysis

Spike Sample Results	Action for Samples
Matrix Spike %R < 30%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R 30-74%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R > 125%	Qualify affected results that are \geq MDL as estimated high (J+) Non-detects are not qualified

Regional Quality Assurance (QA) and Quality Control (QC)**A. Review Items:**

Form I-IN, instrument printouts, and raw data.

B. Objective:

Regional QA/QC samples refer to any QA and/or QC sample initiated by the Region, including field duplicates, Performance Evaluation (PE) samples, blind spikes, and blind blanks. The use of these QA/QC samples is highly recommended (e.g., the use of field duplicates can provide information on sampling precision and homogeneity).

C. Criteria:

Criteria are determined by the Region.

D. Evaluation:

Evaluation procedures must follow the Region's Standard Operating Procedure (SOP) for data review. Each Region will handle the evaluation of PE samples on an individual basis. Compare results for PE samples with the acceptance criteria for the specific PE samples if possible.

Calculate the Relative Percent Difference (RPD) between field duplicates and provide this information in the Data Review Narrative.

E. Action:

Any action must be in accordance with Regional specifications and criteria for acceptable PE sample results. Note any unacceptable PE sample results for Contract Laboratory Program Project Officer (CLP PO) action.

Overall Assessment

A. Review Items:

Entire data package, data review results, preparation logs, calibration standard logs, instrument logs, instrument printouts, and raw data (including any confirmation data).

B. Objective:

The objective is to ensure that the reported sample quantitation results are accurate. It is appropriate for the data reviewer to make professional judgments and express concerns, as well as to comment on the validity of the overall data for a Case. This is particularly appropriate when there are several Quality Control (QC) criteria that are outside of the specification parameters. The additive nature of QC factors that fall outside of specification parameters is difficult to assess in an objective manner, but the reviewer has a responsibility to inform the user concerning data quality and data limitations to assist that user in avoiding inappropriate use of the data, while not precluding any consideration of the data at all. If qualifiers other than those used in this document are necessary to describe or qualify the data, it is necessary to thoroughly document/explain the additional qualifiers used. The data reviewer would be greatly assisted in this endeavor if the acceptance or performance criteria are provided. The Inorganic Review Summary (see Appendix B) and supplementary documentation must be included with the review.

C. Criteria:

1. Review all available materials to assess the overall quality of the data, keeping in mind the additive nature of analytical problems.
2. Reported analyte concentrations must be quantitated according to the appropriate analytical method, as listed in the method.

D. Evaluation:

Examine the raw data to verify that the correct calculation of the sample results was reported by the laboratory. Digestion logs, instrument printouts, etc., should be compared to the reported sample results recorded on the appropriate Inorganic Summary Forms (Form I-IN through Form XV-IN).

1. Evaluate any technical problems not previously addressed.
2. Examine the raw data for any anomalies (e.g., baseline shifts, negative absorbance, omissions, illegibility, etc.).
3. Verify that the appropriate methods and amounts were used to prepare samples and standards for analysis. If reduced volumes are used, verify that the laboratory had received Contract Laboratory Program Project Officer (CLP PO) approval for the use of the reduced volume.
4. Verify that there are no transcription or reduction errors [e.g., dilutions, Percent Solids (%S), sample weights, etc.] on one or more samples.
5. Verify that results fall within the calibrated range for mercury.
6. If appropriate information is available, the reviewer may assess the usability of the data to assist the data user in avoiding inappropriate use of the data. Review all available information, including the Quality Assurance Project Plan (QAPP), focusing specifically on the acceptance or performance criteria, the Standard Operating Procedure(s) (SOPs), and communication with the user concerning the intended use and desired quality of these data.

E. Action:

1. Use professional judgment to determine if there is any need to qualify data which are not qualified based on the QC criteria previously discussed.
2. Write a brief Data Review Narrative to give the user an indication of the analytical limitations of the data. Note any discrepancies between the data and the SDG Narrative for CLP PO action. If sufficient information on the intended use and required quality of the data is available, the reviewer should include an assessment of the data usability within the given context.

3. If any discrepancies are found, the laboratory may be contacted by the Region's designated representative to obtain additional information for resolution. If a discrepancy remains unresolved, the reviewer may determine that qualification of the data is warranted.

Calculations for Mercury**Aqueous/Water Samples:**

$$\text{Hg Concentration (}\mu\text{g/L)} = C \times \text{DF}$$

Where,

- C = Instrument value in $\mu\text{g/L}$ from the calibration curve
DF = Dilution Factor of the original sample

Soil/Sediment Samples:

$$\text{Hg Concentration (mg/kg)} = C \times \frac{1}{W \times S} \times \text{DF} \times 0.1$$

Where,

- C = Instrument value in $\mu\text{g/L}$ from the calibration curve
W = Initial aliquot amount (g)
S = % Solids/100 (see Exhibit D - Introduction to Analytical Methods, Section 1.6).
DF = Dilution Factor

Adjusted Method Detection Limit (MDL)/Adjusted Contract Required Quantitation Limit (CRQL) Calculation:

To calculate the adjusted MDL or adjusted CRQL for aqueous/water samples, multiply the value of the MDL ($\mu\text{g/L}$) or CRQL ($\mu\text{g/L}$) by the Dilution Factor (DF). Calculate the adjusted MDL or adjusted CRQL for soil/sediment samples as follows:

$$\text{Adjusted Concentration (mg/kg)} = C \times \frac{W_m}{W \times S} \times \text{DF}$$

Where,

- C = MDL or CRQL (mg/kg)
 W_m = Method required minimum sample weight (g) (0.50 g)
W = Initial aliquot amount (g)
S = % Solids/100 (see Exhibit D - Introduction to Analytical Methods, Section 1.6).
DF = Dilution Factor

CYANIDE DATA REVIEW

The inorganic data requirements for cyanide data review to be reviewed during validation are listed below:

I.	Preservation and Holding Times	82
II.	Calibration.....	84
III.	Blanks.....	87
IV.	Duplicate Sample Analysis.....	90
V.	Spike Sample Analysis.....	92
VI.	Regional Quality Assurance (QA) and Quality Control (QC).....	95
VII.	Overall Assessment	96

CCB
samples
CCV
CCB, etc.

I. Preservation and Holding Times

A. Review Items:

Form IA-IN, Form IB-IN, Form XII-IN, Form XIII-IN, Traffic Report/Chain of Custody (TR/COC) documentation, Form DC-1, raw data, and the Sample Delivery Group (SDG) Narrative checking for: pH; cooler temperature; holding time; and other sample conditions.

B. Objective:

The objective is to ascertain the validity of the analytical results based on the sample condition, and the holding time of the sample from the date of collection to the date of analysis.

C. Criteria:

1. The technical holding time criteria for aqueous/water cyanide samples is 14 days; oxidizing agents removed, then preserved (with sodium hydroxide) to $\text{pH} \geq 12$. The addition of sodium hydroxide to adjust the pH is only required for aqueous/water samples.
2. The technical holding time criteria for soil/sediment cyanide samples is 14 days, based on the technical holding time criteria for aqueous/water samples.
3. Samples shall be maintained at 4°C ($\pm 2^{\circ}\text{C}$) until preparation and analysis.

D. Evaluation:

Technical holding times are established by comparing the sampling date(s) on the TR/COC documentation with the dates of analysis on Form XIII-IN, and the raw data. Information contained in the Complete SDG File (CSF) should also be considered in the determination of holding times. Verify that the analysis dates on the Form XIII-INs and the raw data are identical. Review the SDG Narrative and raw data preparation logs to determine if samples were properly preserved. If there is an indication that there are problems with the samples, the integrity of the samples may be compromised and professional judgment should be used to evaluate the effect of the problem on the sample results. For aqueous/water cyanide samples, the reviewer should look for evidence that the samples were tested for the presence of sulfides or oxidizing agents, and whether the appropriate preservation steps were taken.

E. Action:

NOTE: Apply the action to each sample for which the preservation or holding time criteria were not met.

1. If oxidizing agents are detected in aqueous/water cyanide samples at the time of sample preparation, qualify results that are \geq Method Detection Limit (MDL) as estimated low (J-) and non-detects as unusable (R). If sulfides are detected in aqueous/water cyanide samples at the time of sample preparation and there is no evidence that the laboratory removed the sulfides (using precipitation and filtration), qualify results that are \geq MDL as estimated (J) and non-detects as unusable (R). If the pH of aqueous/water cyanide samples is < 12 at the time of sample receipt, use professional judgment to qualify the samples based on the pH of the sample. Qualify results that are \geq MDL as estimated low (J-) and qualify non-detects as unusable (R).
2. If technical holding times are exceeded, use professional judgment to determine the reliability of the data based on the magnitude of the additional time compared to the technical requirement and whether the samples are properly preserved. The expected bias would be low. Qualify results that are \geq MDL as estimated low (J-) and non-detects as unusable (R).
3. Due to limited information concerning holding times for soil/sediment samples, it is left to the discretion of the data reviewer whether to apply aqueous/water holding time criteria to soil/sediment samples. If they are applied, it must be clearly documented in the Data Review Narrative.
4. When the holding times are exceeded, the reviewer should comment in the Data Review Narrative on any possible consequences for the analytical results.

5. When holding times are grossly exceeded, note it for Contract Laboratory Program Project Officer (CLP PO) action.

Table 27. Technical Holding Time Actions for Cyanide Analysis

Preservation & Holding Time Results	Action for Samples
Aqueous/water cyanide samples received with oxidizing agents present.	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Aqueous/water cyanide samples received with sulfides present, and sulfides are not removed	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as unusable (R)
Aqueous/water cyanide samples received with pH < 12	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical holding time exceeded: Cyanide > 14 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

Calibration

A. Review Items:

Form II-IN (Part A), Form XI-IN, Form XIII-IN, Form XVI-IN, preparation logs, calibration standard logs, instrument logs, instrument printouts, and raw data.

B. Objective:

Method requirements for satisfactory instrument calibration are established to ensure that the instrument is capable of producing acceptable quantitative data for cyanide. Initial Calibration Verification (ICV) demonstrates that the instrument is capable of acceptable performance at the beginning of the analytical run. Continuing Calibration Verification (CCV) demonstrates that the initial calibration is still valid by checking the performance of the instrument on a continuing basis.

C. Criteria:

1. Initial Calibration

The instruments shall be successfully calibrated daily (or once every 24 hours), and each time the instrument is set up. The calibration date and time shall be included in the raw data.

- a. A blank and at least five calibration standards shall be employed to establish the analytical curve. At least one of the calibration standards shall be at or below the Contract Required Quantitation Limit (CRQL). The calibration curve shall be fitted using linear regression or weighted linear regression. The curve may be forced through zero. The calibration curve for cyanide shall possess a correlation coefficient of ≥ 0.995 to ensure the linearity over the calibrated range. The percent differences calculated for all of the non-zero standards must be within $\pm 30\%$ of the true value of the standard. The y-intercept of the curve must be less than the CRQL.
- b. All sample results shall be reported from an analysis within the calibrated range.
- c. All standards shall be distilled.

2. Initial and Continuing Calibration Verification (ICV and CCV)

The acceptance criteria for the ICVs and CCVs are presented in Table 28:

Table 28. Acceptance Criteria for ICVs and CCVs

Analytical Method	Inorganic Analyte	ICV/CCV Low Limit (% of True Value)	ICV/CCV High Limit (% of True Value)
Colorimetric	Cyanide	85	115

a. Initial Calibration Verification (ICV)

- 1) Immediately after each cyanide colorimetric system has been calibrated, the accuracy of the initial calibration must be verified and documented for cyanide by the analysis of an ICV solution(s). If the ICV %R falls outside of the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and all affected samples reanalyzed.
- 2) If the ICV is not available from USEPA, or where a certified solution of the analyte is not available from any source, analyses shall be conducted on an independent standard at a concentration level other than that used for instrument calibration, but within the calibrated range.
- 3) For cyanide analysis, the ICV standard solution shall be distilled.

- b. Continuing Calibration Verification (CCV)
 - 1) To ensure accuracy during the course of each analytical run, the CCV shall be analyzed and reported.
 - 2) The CCV standard shall be analyzed at a frequency of every hour during an analytical run. The CCV standard shall also be analyzed at the beginning of the run, and again after the last analytical sample.
 - 3) The analyte concentration in the CCV standard shall be different from the concentration used for the ICV, and shall be at the mid level of the calibration curve.
 - 4) The same CCV standard solution shall be used throughout the analysis runs for a Sample Delivery Group (SDG). The CCV shall be distilled.
 - 5) The CCV shall be processed and analyzed in the same fashion as an actual sample. If the %R of the CCV was outside of the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and all analytical samples analyzed since the last compliant CCV reanalyzed.

D. Evaluation:

1. Verify that the instrument was calibrated daily (once every 24 hours) and each time the instrument was set up, utilizing a blank and at least five calibration standards. Confirm that at least one of the calibration standards was analyzed at or below the CRQL.
2. Check the distillation log and verify that the calibration standards, the ICV and the CCVs were distilled and analyzed.
3. Verify that the ICV and CCV standards were analyzed for cyanide at the proper frequency and at the appropriate concentration. Verify that acceptable %R results were obtained.
4. Recalculate one or more of the ICV or CCV %R using the following equation and verify that the recalculated value agrees with the laboratory-reported values on Form IIA -IN.

$$\%R = \frac{\text{Found (value)}}{\text{True (value)}} \times 100$$

Where,

Found (value) = Concentration (in $\mu\text{g/L}$) of cyanide measured in the analysis of the ICV or CCV solution

True (value) = Concentration (in $\mu\text{g/L}$) of cyanide in the ICV or CCV source

E. Action:

NOTES: For initial calibrations or ICVs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCVs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the QC sample and a subsequent technically acceptable analysis of the QC sample in the analytical run.

1. If the instrument was not calibrated daily and each time the instrument was set up, qualify the data as unusable (R). If the instrument was not calibrated with at least the minimum number of standards, or if the calibration curve does not include standards at required concentrations (e.g., a blank and a standard at or below the CRQL), use professional judgment to qualify results that are \geq Method Detection Limit (MDL) as estimated (J) or unusable (R), and non-detects as estimated (UJ) or unusable (R).
2. If the correlation coefficient is < 0.995 , percent differences outside the $\pm 30\%$ limit, or y-intercept \geq CRQL, qualify sample results that are \geq MDL as estimated (J), and non-detects as estimated (UJ).

3. If the standards, the ICV, or the CCVs are not distilled for cyanide, qualify sample results that are \geq MDL as estimated (J).
4. If the ICV or CCV %R falls outside the acceptance windows, use professional judgment to qualify all associated data. If possible, indicate the bias in the review. The following guidelines are recommended:
 - a. If the ICV or CCV %R is $< 70\%$, qualify non-detects as unusable (R). Use professional judgment to qualify all results that are \geq MDL as estimated low (J-) or unusable (R).
 - b. If the ICV or CCV %R falls within the range of 70-84%, qualify sample results that are \geq MDL as estimated low (J-), qualify non-detects as estimated (UJ).
 - c. If the ICV or CCV %R falls within the range of 116-130%, qualify sample results that are \geq MDL as estimated high (J+).
 - d. If the ICV or CCV %R is within the range of 116-130%, non-detects should not be qualified.
 - e. If the ICV or CCV %R is $> 130\%$, use professional judgment to qualify results that are \geq MDL as estimated high (J+) or unusable (R). Non-detects should not be qualified.
 - f. If the %R is $> 165\%$, qualify all results that are \geq MDL as unusable (R).
5. If the laboratory failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
6. Note the potential effects on the reported data due to exceeding the calibration criteria in the Data Review Narrative.
7. If calibration criteria are grossly exceeded, note this for Contract Laboratory Program Project Officer (CLP PO) action.

NOTE: For truly critical samples, a further in-depth evaluation of the calibration curve may be warranted to determine if additional qualification is necessary.

Table 29. Calibration Actions for Cyanide Analysis

Calibration Result	Action for Samples
Calibration not performed	Qualify all results as unusable (R)
Calibration incomplete	Use professional judgment Qualify results that are \geq MDL as estimated (J) or unusable (R) Qualify non-detects as estimated (UJ) or unusable (R)
Correlation coefficient < 0.995 ; %D outside $\pm 30\%$, y-intercept \geq CRQL	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Standards and QC not distilled	Qualify results that are \geq MDL as estimated (J)
ICV/CCV %R $< 70\%$	Qualify results that are \geq MDL as estimated low (J-) or unusable (R) Qualify all non-detects as unusable (R)
ICV/CCV %R 70-84%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICV/CCV %R 116-130%	Qualify results that are \geq MDL as estimated (J)
ICV/CCV %R $> 130\%$	Qualify results that are \geq MDL as estimated high (J+) or unusable (R)
ICV/CCV %R $> 165\%$	Qualify results that are \geq MDL as unusable (R)

Blanks

A. Review Items:

Form I-IN, Form III-IN, Form XII-IN, Form XIII-IN, preparation logs, calibration standard logs, instrument logs, and raw data.

B. Objective:

The objective of blank analysis results assessment is to determine the existence and magnitude of contamination resulting from laboratory (or field) activities. The criteria for evaluation of blanks apply to any blank associated with the samples (e.g., method blanks, calibration blanks, field blanks, etc.). If problems with any blank exist, all associated data must be carefully evaluated to determine whether or not there is an inherent variability in the data, or if the problem is an isolated occurrence not affecting other data.

C. Criteria:

1. No contaminants should be found in the blank(s).
2. The Initial Calibration Blank (ICB) shall be analyzed after the analytical standards, but not before analysis of the Initial Calibration Verification (ICV) during the initial calibration of the instrument (see Section II.C.1).
3. A Continuing Calibration Blank (CCB) shall be analyzed immediately after every Continuing Calibration Verification (CCV). The CCB shall be analyzed at a frequency of every hour during the run. The CCB shall be analyzed at the beginning of the run, and again after the last CCV that was analyzed after the last analytical sample of the run. The CCB result (absolute value) shall not exceed the Contract Required Quantitation Limit (CRQL) of cyanide.
4. At least one Preparation Blank shall be prepared and analyzed for each matrix, with every Sample Delivery Group (SDG), or with each batch of samples distilled, whichever is more frequent. The Preparation Blank consists of reagent water processed through the appropriate sample preparation and analysis procedure.
5. If the cyanide concentration in the Preparation Blank is $> \text{CRQL}$, the lowest concentration of cyanide in the associated samples must be ≥ 10 times (10x) the Preparation Blank concentration. Otherwise, all samples associated with that Preparation Blank with a cyanide concentration $< 10x$ the Preparation Blank concentration, and $> \text{CRQL}$, should be redistilled and reanalyzed cyanide (except for an identified field blank). The laboratory is not to correct the sample concentration for the blank value.
6. If the concentration of the Preparation Blank for cyanide is $< (-\text{CRQL})$, all samples reported $< 10x$ the CRQL (associated with that blank), should be redistilled and reanalyzed.

D. Evaluation:

1. Verify that an ICB was analyzed after the calibration, the CCB was analyzed at the proper frequency and location during the run, and Preparation Blanks are prepared and analyzed as appropriate for the SDG (e.g., total number of samples, various types of matrices present, number of digestion batches, etc.).
2. Review the results reported on the Blank Summary (Form III-IN), as well as the raw data for all blanks, and verify that the results were accurately reported.
3. Evaluate all of the associated blanks for the presence of cyanide. Verify that if cyanide was present in a Preparation Blank or if a concentration was $< (-\text{CRQL})$, the affected samples were redistilled and reanalyzed. Verify that if cyanide was present in an ICB or a CCB, the analysis was terminated, the problem corrected, the instrument recalibrated, and the preceding 10 analytical samples or all analytical samples analyzed since the last compliant calibration blank reanalyzed.

E. Action:

NOTES: For ICBs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCBs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the CCB and a subsequent technically acceptable analysis of the CCB in the analytical run.

For Preparation Blanks that do not meet the technical criteria, apply the action to all samples prepared in the same preparation batch.

1. If the appropriate blanks are not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank (including Preparation Blanks) reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank (including Preparation Blanks) reported with a negative result, whose value is $<$ (-CRQL) qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. Specific “method” actions include:
 - a. If the absolute value of an ICB or a CCB result is $>$ CRQL, the analysis should be terminated. If the analysis was not terminated and the affected samples are not reanalyzed, report non-detects and results that are \geq MDL but \leq CRQL as CRQL-U. For results that are $>$ CRQL but $<$ Blank Result, use professional judgment to qualify the data as unusable (R), or report the results at the level of the blank with a “U” qualifier. Use professional judgment to qualify results that are $>$ Blank Result. Note this situation for CLP PO action and record it in the Data Review Narrative.
 - b. If the absolute value of the concentration of the Preparation Blank is \leq CRQL, no correction of the sample results should be performed, report non-detects and results \geq MDL but \leq CRQL as CRQL-U. Use professional judgment to qualify results that are $>$ CRQL.
 - c. If the cyanide concentration in the Preparation Blank is $>$ CRQL, the lowest concentration of cyanide in the associated samples must be 10x the Preparation Blank concentration. Otherwise, all samples associated with that blank with concentrations $<$ 10x the Preparation Blank concentration and $>$ CRQL should be redistilled and reanalyzed. Raise the CRQL to the concentration found in the Preparation Blank and report those samples that do not require redistillation (that are \geq MDL but \leq CRQL) as CRQL-U. Note for CLP PO action and record in the Data Review Narrative if the laboratory failed to redistill and reanalyze the affected samples. The reviewer shall then use professional judgment to assess the data.

Table 30. Blank Actions for Cyanide Analysis

Blank Type	Blank Result	Sample Result	Action for Samples
ICB/CCB	Absolute value is \geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
ICB/CCB	Absolute value is $>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ Blank Result	Report at level of Blank Result with a "U" or qualify data as unusable (R)
		$>$ Blank Result	Use professional judgment
ICB/CCB	\leq (-MDL), but \geq (-CRQL)	\geq MDL, or non-detects	Use professional judgment
ICB/CCB	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)
Preparation Blank	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ 10x the Blank Result	Qualify results as unusable (R) or estimated high (J+)
		\geq 10x the Blank Result	No action
Preparation Blank	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
Preparation Blank	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)

Duplicate Sample Analysis

A. Review Items:

Cover Page, Form VI-IN, Form XII-IN, instrument printouts, and raw data.

B. Objective:

The objective of duplicate sample analysis is to demonstrate acceptable method precision by the laboratory at the time of analysis. Duplicate analyses are also performed to generate data that determines the long-term precision of the analytical method on various matrices. Non-homogenous samples can impact the apparent method precision. However, aqueous/water samples are generally homogenous and most soil/sediment samples are homogenous within a factor of two or three.

C. Criteria:

1. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for duplicate sample analysis.
2. At least one duplicate sample shall be prepared and analyzed from each group of samples of a similar matrix type (e.g., water or soil) or for each Sample Delivery Group (SDG). Duplicates cannot be averaged for reporting on Form I-IN. Additional duplicate sample analyses may be required by USEPA Regional request. Alternately, the Region may require that a specific sample be used for the duplicate sample analysis.
3. A control limit of 20% for the Relative Percent Difference (RPD) shall be used for original and duplicate sample values \geq five times (5x) the Contract Required Quantitation Limit (CRQL).
4. A control limit of the CRQL shall be used if either the sample or duplicate value is $< 5x$ the CRQL. The absolute value of the control limit (CRQL) shall be entered in the "Control Limit" column on Form VI-IN. If both samples are non-detects, the RPD is not calculated for Form VI-IN.

NOTE: The above control limits are **method requirements** for duplicate samples, regardless of the sample matrix type. However, it should be noted that laboratory variability arising from the sub-sampling of non-homogenous soil samples is a common occurrence. Therefore, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., 35% RPD, 2x the CRQL) to be assessed against duplicate soil samples.

D. Evaluation:

1. Verify from the Cover Page, Form XII-IN, and the raw data that the appropriate number of required duplicate samples were prepared and analyzed for the SDG.
2. Evaluate Form VI-IN and the raw data to verify that all cyanide duplicate results for each method fall within the established control limits.
3. Verify that a field blank or PE sample was not used for duplicate analysis.
4. Check the raw data and recalculate one or more of the RPD values using the following equation to verify that the results were correctly reported on Form VI-IN:

$$RPD = \frac{|S - D|}{(S + D)/2} \times 100$$

Where,

- RPD = Relative Percent Difference
S = Sample result (original)
D = Duplicate result

E. Action:

NOTE: For a duplicate sample analysis that does not meet the technical criteria, apply the action to all samples of the same matrix, if the reviewer considers the samples sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions], in determining similarity. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar to the duplicate sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for the duplicate, and thus that only the field sample used to prepare the duplicate sample should be qualified.

1. If the appropriate number of duplicate samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for Contract Laboratory Program Project Officer (CLP PO) action.
2. If the results from a duplicate analysis for cyanide fall outside the appropriate control limits, qualify sample results that are \geq Method Detection Limit (MDL) as estimated (J) and non-detects as estimated (UJ).
3. If a field blank or PE sample was used for the duplicate sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
4. Note the potential effects on the data due to out-of-control duplicate sample results in the Data Review Narrative.

Table 31. Duplicate Sample Actions for Cyanide Analysis

Duplicate Sample Results	Action for Samples
Both original sample and duplicate sample $> 5x$ the CRQL and RPD $> 20\%$ *	Qualify those results that are \geq MDL that professional judgment determines to be affected as estimated (J) and non-detects as estimated (UJ)
Original sample or duplicate sample $\leq 5x$ the CRQL (including non-detects) and absolute difference between sample and duplicate $> CRQL$ *	Qualify those results that are \geq MDL that professional judgment determines to be affected as estimated (J) and non-detects as estimated (UJ)

- * The above control limits are **method requirements** for duplicate samples, regardless of the sample matrix type. However, it should be noted that laboratory variability arising from the sub-sampling of non-homogenous soil samples is a common occurrence. Therefore, for **technical review purposes only**, Regional policy or project Data Quality Objectives (DQOs) may allow the use of less restrictive criteria (e.g., 35% RPD, 2x the CRQL) to be assessed against duplicate soil samples.

Spike Sample Analysis

A. Review Items:

Cover Page, Form V-IN (Parts A & B), Form XII-IN, instrument printouts, and raw data.

B. Objective:

The spiked sample analysis is designed to provide information about the effect of each sample matrix on the sample preparation procedures and the measurement methodology. Non-homogenous samples can impact the apparent method recovery. However, aqueous/water samples are generally homogenous and most soil/sediment samples are homogenous within a factor of two or three. If the spike is added to the sample prior to any distillation steps (e.g., cyanide), it is referred to as a spiked sample, pre-distillation spike, or Matrix Spike. If the spike is added to the sample after the completion of the distillation procedures, it is referred to as a post-distillation spike, or analytical spike.

C. Criteria:

1. Samples identified as field blanks or Performance Evaluation (PE) samples cannot be used for spiked sample analysis.
2. At least one spiked sample (pre-distillation) shall be prepared and analyzed from each group of samples with a similar matrix type (e.g., water or soil), or for each Sample Delivery Group (SDG).
3. When the pre-distillation spike recovery falls outside of the control limits and the sample result is < four times (4x) the spike added, a post-distillation spike shall be performed. An aliquot of the remaining unspiked sample shall be spiked at 2x the indigenous level or 2x the Contract Required Quantitation Limit (CRQL), whichever is greater.
4. The spike Percent Recovery (%R) shall be within the established acceptance limits. However, spike recovery limits do not apply when the sample concentration is 4x the spike added. In such an event, the data shall be reported unflagged, even if the %R does not meet the acceptance criteria.
5. If the spiked sample analysis was performed on the same sample that was chosen for the duplicate sample analysis, spike calculations shall be performed using the results of the sample designated as the "original sample". The average of the duplicate results cannot be used for the purpose of determining %R.

NOTE: The final spike concentrations required for cyanide are presented in the method described in the Statement of Work (SOW).

D. Evaluation:

1. Verify using the Cover Page, Form VA-IN, Form XII-IN, and raw data that the appropriate number of required spiked samples were prepared and analyzed for the SDG.
2. Verify that a field blank or PE sample was not used for the spiked sample analysis.
3. Evaluate Form VA-IN and the raw data to verify that all pre-distillation spiked sample results fall within the established control limits. If not, verify that a post-distillation spike was prepared and analyzed.
4. Recalculate using the raw data, one or more of the %R using the following equation, and verify that the recalculated value agrees with the laboratory-reported values on Forms V (A & B)-IN:

$$\% \text{Recovery} = \frac{\text{SSR} - \text{SR}}{\text{SA}} \times 100$$

Where,

- SSR = Spiked Sample Result
 SR = Sample Result
 SA = Spike Added

NOTE: When the sample concentration is < Method Detection Limit (MDL), use SR = 0 only for the purposes of calculating the %R. The actual spiked sample results, sample results, and %R (positive or negative) shall still be reported on Form V (A & B)-IN.

E. Action:

NOTE: For a Matrix Spike that does not meet the technical criteria, apply the action to all samples of the same matrix, if the reviewer considers the samples sufficiently similar. The reviewer will need to exercise professional judgment in determining sample similarity. The reviewer should make use of all available data, including: site and sampling documentation (e.g., location and type of sample, descriptive data, soil classification); field test data (e.g., pH, Eh, conductivity, chlorine); and laboratory data for other parameters [e.g., Total Suspended Solids (TSSs), Total Dissolved Solids (TDSs), Total Organic Carbon (TOC), alkalinity or buffering capacity, reactive sulfide, anions], in determining similarity. The reviewer should also use the sample data (e.g., similar concentrations of analytes) in determining similarity between samples in the SDG. The reviewer may determine that only some of the samples in the SDG are similar to the Matrix Spike sample, and that only these samples should be qualified. Or, the reviewer may determine that no samples are sufficiently similar to the sample used for the Matrix Spike, and thus that only the field sample used to prepare the Matrix Spike sample should be qualified.

1. If the appropriate number of Matrix Spike samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for CLP Project Officer (CLP PO) action.
2. If a field blank or PE sample was used for the spiked sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
3. If the Matrix Spike recovery does not meet the evaluation criteria and a required post-distillation spike was not performed, note this for CLP PO action.
4. If the Matrix Spike %R is < 30%, verify that a post-distillation spike was analyzed if required. If the post-distillation spike %R is < 75% or is not performed, qualify sample results that are \geq MDL as estimated low (J-) and non-detects as unusable (R). If the post-distillation spike %R is \geq 75%, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
5. If the Matrix Spike %R falls within the range of 30-74% and the sample results are \geq MDL, verify that a post-distillation spike was analyzed if required. If the %R for the post-distillation spike is also < 75% or not performed, qualify the affected data as estimated low (J-). If the %R for the post-distillation spike is \geq 75%, qualify the affected data as estimated (J).
6. If the Matrix Spike %R falls within the range of 30-74% and the sample results are non-detects, qualify the affected data as estimated (UJ).
7. If the Matrix Spike %R is > 125% and the reported sample results are non-detects, the sample data should not be qualified.
8. If the Matrix Spike %R is > 125% and the sample results are \geq MDL, verify that a post-distillation spike was analyzed if required. If the %R for the post-distillation spike is also > 125% or is not performed, qualify the affected data as estimated high (J+). If the %R for the post-distillation spike is \leq 125%, qualify the affected data as estimated (J).
9. Note the potential effects on the data due to out-of-control spiked sample results in the Data Review Narrative.

Table 32. Spike Sample Actions for Cyanide Analysis

Spike Sample Results	Action for Samples
Matrix Spike %R < 30% Post-distillation spike %R < 75%	Qualify affected results that are \geq MDL as estimated low (J-) Qualify affected non-detects as unusable (R)
Matrix Spike %R < 30% Post-distillation spike %R \geq 75%	Qualify affected results that are \geq MDL as estimated (J) Qualify affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-distillation spike %R < 75%	Qualify affected results that are \geq MDL as estimated low (J-) Qualify affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-distillation spike %R \geq 75%	Qualify affected results that are \geq MDL as estimated (J) Qualify affected non-detects as estimated (UJ)
Matrix Spike %R > 125% Post-distillation spike %R > 125%	Qualify affected results that are \geq MDL as estimated high (J+)
Matrix Spike %R > 125% Post-distillation spike %R \leq 125%	Qualify affected results that are \geq MDL as estimated (J)
Matrix Spike %R < 30% No post-distillation spike performed	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R 30-74% No post-distillation spike performed	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R > 125% No post-distillation spike performed	Qualify affected results that are \geq MDL as estimated high (J+) Non-detects are not qualified

Regional Quality Assurance (QA) and Quality Control (QC)**A. Review Items:**

Form I-IN, instrument printouts, and raw data.

B. Objective:

Regional QA/QC samples refer to any QA and/or QC sample initiated by the Region, including field duplicate samples, Performance Evaluation (PE) sample, blind spikes, and blind blanks. The use of these QA/QC samples is highly recommended (e.g., the use of field duplicates can provide information on sampling precision and homogeneity).

C. Criteria:

Criteria are determined by each Region.

D. Evaluation:

Evaluation procedures must follow the Region's Standard Operating Procedure (SOP) for data review. Each Region will handle the evaluation of PE samples on an individual basis. Compare results for PE samples to the acceptance criteria for the specific PE samples if possible.

Calculate the Relative Percent Difference (RPD) between field duplicates and provide this information in the Data Review Narrative.

E. Action:

Any action must be in accordance with Regional specifications and criteria for acceptable PE sample results. Note any unacceptable PE sample results for Contract Laboratory Program Project Officer (CLP PO) action.

Overall Assessment

A. Review Items:

Entire data package, data review results, preparation logs, calibration standard logs, instrument logs, instrument printouts, and raw data (including any confirmation data).

B. Objective:

The objective is to ensure that the reported sample quantitation results are accurate. It is appropriate for the data reviewer to make professional judgments and express concerns, as well as to comment on the validity of the overall data for a Case. This is particularly appropriate when there are several Quality Control (QC) criteria that are outside of the specification parameters. The additive nature of QC factors that fall outside of specification parameters is difficult to assess in an objective manner, but the reviewer has a responsibility to inform the user concerning data quality and data limitations to assist that user in avoiding inappropriate use of the data, while not precluding any consideration of the data at all. If qualifiers other than those used in this document are necessary to describe or qualify the data, it is necessary to thoroughly document/explain the additional qualifiers used. The data reviewer would be greatly assisted in this endeavor if the acceptance or performance criteria were provided. The Inorganic Review Summary (see Appendix B) and supplementary documentation must be included with the review.

C. Criteria:

1. Review all available materials to assess the overall quality of the data, keeping in mind the additive nature of analytical problems.
2. Reported analyte concentrations must be quantitated according to the appropriate analytical method, as listed in the method.

D. Evaluation:

Examine the raw data to verify that the correct calculation of the sample results was reported by the laboratory. Distillation logs, instrument printouts, etc., should be compared to the reported sample results recorded on the appropriate Inorganic Summary Forms (Form I-IN through Form XV-IN).

1. Evaluate any technical problems not previously addressed.
2. Examine the raw data for any anomalies (e.g., baseline shifts, negative absorbance, omissions, illegibility, etc.).
3. Verify that the appropriate methods and amounts were used to prepare samples for analysis. If reduced volumes were used, verify that the laboratory had received Contract Laboratory Program Project Officer (CLP PO) approval for the use of the reduced volume.
4. Verify that there were no transcription or reduction errors [e.g., dilutions, Percent Solids (%S), sample weights, etc.] on one or more samples.
5. Verify that results fall within the calibrated range for cyanide.
6. If appropriate information is available, the reviewer may assess the usability of the data to assist the data user in avoiding inappropriate use of the data. Review all available information, including the Quality Assurance Project Plan (QAPP), focusing specifically on the acceptance or performance criteria, the Standard Operating Procedure(s) (SOPs), and communication with user concerning the intended use and desired quality of these data.

E. Action:

1. Use professional judgment to determine if there is any need to qualify data which were not qualified based on the QC criteria previously discussed.
2. Write a brief Data Review Narrative to give the user an indication of the analytical limitations of the data. Note any discrepancies between the data and the SDG Narrative for CLP PO action. If sufficient information on the intended use and required quality of the data is available, the reviewer should include an assessment of the data usability within the given context.

3. If any discrepancies are found, the laboratory may be contacted by the Region's designated representative to obtain additional information for resolution. If a discrepancy remains unresolved, the reviewer may determine that qualification of the data is warranted.

Calculations for Cyanide**Aqueous/Water Sample Concentration:**

$$\text{CN Concentration (ug/L)} = C \times \frac{V_f}{V} \times \text{DF}$$

Where,

- C = Instrument response in $\mu\text{g/L}$ CN from the calibration curve
 V_f = Final prepared (absorbing solution) volume (mL)
 V = Initial aliquot amount (mL)
 DF = Dilution Factor

Soil/Sediment Sample Concentration:

$$\text{CN Concentration (mg/kg)} = C \times \frac{V_f}{W \times S} \times (1/1000) \times \text{DF}$$

Where,

- C = Instrument response in $\mu\text{g/L}$ CN from the calibration curve
 V_f = Final prepared (absorbing solution) volume (mL)
 W = Initial aliquot amount (g)
 S = % Solids/100 (see Exhibit D - Introduction to Analytical Methods, Section 1.6)
 DF = Dilution Factor

Adjusted Method Detection Limit (MDL)/Adjusted Contract Required Quantitation Limit (CRQL) Calculation:

To calculate the adjusted aqueous/water MDL or adjusted aqueous/water CRQL, follow the instructions in Exhibit D - Data Analysis and Calculations, Section 11.1.1.

The adjusted soil/sediment MDL or adjusted soil/sediment CRQL for all methods shall be calculated as follows:

$$\text{Adjusted Concentration (mg/kg)} = C \times \frac{W_M}{W \times S} \times \text{DF}$$

Where,

- C = MDL or CRQL (mg/kg)
 W_M = Minimum method required aliquot amount (1.00 g for Midi or 0.50 g for Micro)
 W = Initial aliquot amount (g)
 S = % Solids/100 (see Exhibit D - Introduction to Analytical Methods, Section 1.6).
 DF = Dilution Factor

APPENDIX A: GLOSSARY

Analyte -- The element of interest, ion, or parameter an analysis seeks to determine.

Analytical Services Branch (ASB) -- Directs the Contract Laboratory Program (CLP) from within the Office of Superfund Remediation and Technical Innovation (OSRTI) in the Office of Solid Waste and Emergency Response (OSWER).

Analytical Sample -- Any solution or media introduced into an instrument on which an analysis is performed excluding instrument calibration, Initial Calibration Verification (ICV), Initial Calibration Blank (ICB), Continuing Calibration Verification (CCV), and Continuing Calibration Blank (CCB). Note that the following are all defined as analytical samples: undiluted and diluted samples (USEPA and non-USEPA); Matrix Spike samples; duplicate samples; serial dilution samples, analytical (post-digestion/post-distillation) spike samples; Interference Check Samples (ICSs); Laboratory Control Samples (LCSs); and Preparation Blanks.

Associated Samples -- Any sample related to a particular Quality Control (QC) analysis. For example, for Initial Calibration Verification (ICV), all samples run under the same calibration curve. For duplicates, all Sample Delivery Group (SDG) samples digested/distilled of the same matrix.

Blank -- A sample designed to assess specific sources of contamination. See individual definitions for types of blanks.

Calibration -- The establishment of an analytical curve based on the absorbance, emission intensity, or other measured characteristic of known standards. The calibration standards are to be prepared using the same type of reagents or concentration of acids as used in the sample preparation.

Calibration Blank -- A blank solution containing all of the reagents in the same concentration as those used in the analytical sample preparation. This blank is not subject to the preparation method.

Calibration Curve -- A plot of instrument response versus concentration of standards.

Calibration Standards -- A series of known standard solutions used by the analyst for calibration of the instrument (i.e., preparation of the analytical curve). The solutions may or may not be subjected to the preparation method, but contain the same matrix (i.e., the same amount of reagents and/or preservatives) as the sample preparations to be analyzed.

Case -- A finite, usually predetermined number of samples collected over a given time period from a particular site. Case numbers are assigned by the Sample Management Office (SMO). A Case consists of one or more Sample Delivery Groups (SDGs).

Continuing Calibration Blank (CCB) -- A reagent water sample that is run 2 hours (ICP-AES, ICP-MS) or every hour (Hg, CN) and designed to detect any carryover contamination.

Contract Compliance Screening (CCS) -- A screening of electronic and hardcopy data deliverables for completeness and compliance with the contract. This screening is performed under USEPA direction by the Contract Laboratory Program (CLP) Sample Management Office (SMO) contractor.

Continuing Calibration Verification (CCV) -- A single parameter or multi-parameter standard solution prepared by the analyst and used to verify the stability of the instrument calibration with time, and the instrument performance during the analysis of samples. The CCV can be one of the calibration standards. However, all parameters being measured by the particular system must be represented in this standard and the standard must have the same matrix (i.e., the same amount of reagents and/or preservatives) as the samples. The CCV should have a concentration in the middle of the calibration range and shall be run every 2 hours (ICP-AES, ICP-MS) or every hour (Hg, CN).

Contract Laboratory Program (CLP) -- Supports the USEPA's Superfund effort by providing a range of state-of-the-art chemical analytical services of known quality. This program is directed by the Analytical Services Branch (ASB) of the Office of Superfund Remediation and Technical Innovation (OSRTI) of USEPA.

Contract Laboratory Program Project Officer (CLP PO) -- The Regional USEPA official responsible for monitoring laboratory performance and/or requesting analytical data or services from a CLP laboratory.

Contract Required Quantitation Limit (CRQL) -- Minimum level of quantitation acceptable under the contract Statement of Work (SOW).

Duplicate -- A second aliquot of a sample that is treated the same as the original sample in order to determine the precision of the method.

Field Blank -- Any sample that is submitted from the field and identified as a blank. A field blank is used to check for cross-contamination during sample collection, sample shipment, and in the laboratory. A field blank includes trip blanks, rinsate blanks, bottle blanks, equipment blanks, preservative blanks, decontamination blanks, etc.

Field Duplicate -- A duplicate sample generated in the field, not in the laboratory.

Holding Time -- The maximum amount of time samples may be held before they are processed.

Contractual -- The maximum amount of time that the Contract Laboratory Program (CLP) laboratory may hold the samples from the sample receipt date until analysis and still be in compliance with the terms of the contract, as specified in the CLP Analytical Services Statement of Work (SOW). These times are the same or less than technical holding times to allow for sample packaging and shipping.

Technical -- The maximum amount of time that samples may be held from the collection date until analysis.

Initial Calibration -- Analysis of analytical standards for a series of different specified concentrations to define the quantitative response, linearity, and dynamic range of the instrument to target analytes.

Initial Calibration Blank (ICB) -- The first blank standard run to confirm the calibration curve.

Initial Calibration Verification (ICV) -- Solution(s) prepared from stock standard solutions, metals, or salts obtained from a source separate from that utilized to prepare the calibration standards. The ICV is used to verify the concentration of the calibration standards and the adequacy of the instrument calibration. The ICV should be traceable to National Institute of Standards and Technology (NIST) or other certified standard sources when USEPA ICV solutions are not available.

Internal Standard -- A non-target element added to a sample at a known concentration after preparation but prior to analysis. Instrument responses to internal standards are monitored as a means of assessing overall instrument performance.

Interference Check Sample (ICS) -- Verifies the contract laboratory's ability to overcome interferences typical of those found in samples.

Laboratory Control Sample (LCS) -- A control sample spiked at known level(s). LCSs are processed using the same sample preparation, reagents, and analytical methods employed for the USEPA samples received.

Matrix -- The predominant material of which the sample to be analyzed is composed. For the purposes of this document, the matrices are aqueous/water, soil/sediment, wipe, and filter.

Matrix Spike -- Introduction of a known concentration of analyte into a sample to provide information about the effect of the sample matrix on the digestion and measurement methodology (also identified as a pre-distillation/digestion spike).

Method Detection Limit (MDL) -- The concentration of a target parameter that, when a sample is processed through the complete method, produces a signal with 99 percent probability that it is different from the blank. For 7 replicates of the sample, the mean value must be 3.14s above the blank, where "s" is the standard deviation of the 7 replicates.

Narrative (SDG Narrative) -- Portion of the data package which includes laboratory, contract, Case, Sample Number identification, and descriptive documentation of any problems encountered in processing the samples, along with corrective action taken and problem resolution.

Office of Solid Waste and Emergency Response (OSWER) -- The USEPA office that provides policy, guidance, and direction for the USEPA's solid waste and emergency response programs, including Superfund.

Percent Difference (%D) -- As used in this document and the Statement of Work (SOW), is used to compare two values. The difference between the two values divided by one of the values.

Performance Evaluation (PE) Sample -- A sample of known composition provided by USEPA for contractor analysis. Used by USEPA to evaluate Contractor performance.

Post Digestion Spike -- The addition of a known amount of standard after digestion or distillation (also identified as an analytical spike).

Preparation Blank -- An analytical control that contains reagent water and reagents, which is carried through the entire preparation and analytical procedure.

Relative Percent Difference (RPD) -- As used in this document and the Statement of Work (SOW) to compare two values, the RPD is based on the mean of the two values, and is reported as an absolute value (i.e., always expressed as a positive number or zero).

Regional Sample Control Center Coordinator (RSCC) -- In USEPA Regions, coordinates sampling efforts and serves as the central point-of-contact for sampling questions and problems. Also assists in coordinating the level of Regional sampling activities to correspond with the monthly projected demand for analytical services.

Relative Standard Deviation (RSD) -- As used in this document and the Statement of Work (SOW), the mean divided by the standard deviation, expressed as a percentage.

Sample -- A single, discrete portion of material to be analyzed, which is contained in single or multiple containers and identified by a unique Sample Number.

Sample Delivery Group (SDG) -- A unit within a sample Case that is used to identify a group of samples for delivery. An SDG is defined by the following, whichever is most frequent:

- a. Each 20 field samples [excluding Performance Evaluation (PE) samples] within a Case; or
- b. Each 7 calendar day period (3 calendar day period for 7-day turnaround) during which field samples in a Case are received (said period beginning with the receipt of the first sample in the SDG).
- c. Scheduled at the same level of deliverable.

In addition, all samples and/or sample fractions assigned to an SDG must be scheduled under the same contractual turnaround time. Preliminary Results have **no impact** on defining the SDG. Samples may be assigned to SDGs by matrix (i.e., all soil/sediment samples in one SDG, all aqueous/water samples in another) at the discretion of the laboratory.

Sample Management Office (SMO) -- A contractor-operated facility operated under the SMO contract, awarded and administered by the USEPA. Provides necessary management, operations, and administrative support to the Contract Laboratory Program (CLP).

Serial Dilution -- The dilution of a sample by a factor of five. When corrected by the Dilution Factor (DF), the diluted sample must agree with the original undiluted sample within specified limits. Serial dilution may reflect the influence of interferences [Inductively Coupled Plasma (ICP) only].

Statement of Work (SOW) -- A document which specifies how laboratories analyze samples under a particular Contract Laboratory Program (CLP) analytical program.

Tune -- Analysis of a solution containing a range of isotope masses to establish Inductively Coupled Plasma - Mass Spectrometry (ICP-MS) mass-scale accuracy, mass resolution, and precision prior to calibration.

Action: If "no", contact the laboratory or field personnel as appropriate for submittal of missing or illegible information.			
III. Sample Handling and Receipt			
1. Were samples received at the appropriate temperature (0-10°C)? Record cooler temps: _____ °C	—	—	—
2. Were samples received with proper preservation?	—	—	—
3. Were any deviations from project required sample handling, receipt, or storage documented?	—	—	—
Action: If "no", contact the laboratory or field personnel for submittal of missing or illegible information. Document the non-conformance and associated samples along with potential data limitations and attach to this checklist.

IV. Final Data / EDD			
1. Was a Case Narrative including the following present for each analysis group?			
▪ Identification of QC samples	—	—	—
▪ Communication logs	—	—	—
▪ Corrective action reports	—	—	—
▪ Documentation of corrective action results	—	—	—
▪ Documentation of laboratory method deviations	—	—	—
▪ Signatures for laboratory sign-off	—	—	—
2. Were results reported for all analytes specified in the QAPP for each analysis group (see applicable table in worksheet #15)?	—	—	—
3. Were project specified quantitation limits achieved (see applicable table in worksheet #15)?	—	—	—
4. Were project specified laboratory data qualifiers used (see worksheet #29-3)?	—	—	—
5. Perform a 10% transcription check, i.e., from laboratory instrument to form. Was the accuracy of transcription verified?	—	—	—
6. Compare results on Form 1s to EDD. Is the EDD free of transcription errors?	—	—	—
Action: If "no", contact the laboratory or field personnel for submittal of missing or illegible information. Document the non-conformance and associated samples along with potential data limitations and attach to this checklist.			
V. Holding Time			
1. Were solid and liquid samples analyzed within 7 days of collection?	—	—	—
2. If holding times were not met, were deviations documented, appropriate notifications made and approval to proceed obtained?	—	—	—
Action: If "no", contact the laboratory or field personnel for submittal of missing or illegible information. Document the non-conformance and associated samples along with potential data limitations and attach to this checklist.			
VI. Sampling and Analytical Methods and Procedures			
1. Were required sampling and field measurement methods used and were any deviations noted (see QAPP Worksheet #21)?	—	—	—
2. Were required analytical methods used and were any deviations noted (see QAPP Worksheet #23-1)?	—	—	—
Action: If "no", contact the laboratory or field personnel for submittal of missing or illegible information. Document the non-conformance and associated samples along with potential data limitations and attach to this checklist.			

Environmental Data Services
SOP V-12
Verification/Validation
Sulfide

	<u>Y</u>	<u>N</u>	<u>N/A</u>
VII. Blanks			
1. Were the preparation (extraction) blanks associated with the samples free of contamination (i.e., no target compound > PQL)?	—	—	—
2. Were the rinsate blanks associated with the samples free of contamination (i.e., no target compound > PQL)?	—	—	—
Action: Document non-conformance and associated samples along with potential data limitations and attach to this checklist.			
VIII. Matrix Spike (MS)			
1. Were the matrix spike recoveries within the project specified limits or 75-125% for Sediment?	—	—	—
Action: Document non-conformance and associated samples along with potential data limitations and attach to this checklist.			
IX. Lab Duplicates			
1. Were the % RPD (% Reproducibility) between laboratory duplicates within the project specified limit of 35% when target in both original and lab duplicate samples are >5x PQL or concentrations differ by <2x PQL when detects are <5x PQL for Sediment?	—	—	—
Action: Document non-conformance and associated samples along with potential data limitations and attach to this checklist.			
X. Laboratory Control Sample (LCS)			
1. Were the LCS recoveries within the project specified limits described below:			
Liquid 80-120%	—	—	—
Sediment certified acceptance range noted on Form VII	—	—	—
Action: Document non-conformance and associated samples along with potential data limitations and attach to this checklist.			
XI. Field Duplicate			
1. Were the % RPD between sample and field duplicate within the project specified limits, i.e.,			
RPD <100% when target in both field duplicate samples are >5x PQL?	—	—	—
or			
Concentrations differ by <2x PQL when detects are <5x PQL?	—	—	—
Action: Document non-conformance and associated samples along with potential data limitations and attach to this checklist.

Completeness Check Questions	Y	N	N/A
1. Are all samples in this sample delivery group (SDG) present on the bench worksheet log? Note: Worksheet log located in the dioxin extraction section of data package.			
2. Has a method blank been analyzed per analytical batch or every 20 samples?			
3. Spot check one sample calculation. Were errors identified during calculation check? Note: % lipid = [weight of residue (g)/weight of tissue (g)] x 100			
4. Did the laboratory perform a laboratory duplicate sample? If yes, provide below: <div style="text-align: center; margin-left: 150px;"> Sample ID: _____ % RPD= _____ </div> If no, explain below: Note: Adequate laboratory precision is demonstrated when % RPD ≤ 50%.			
5. Did the laboratory report the % lipid results for each sample on the dioxin data sheets?			
6. Is the correct number of significant figures (3) used on the data sheets?			
7. Were any problems noted? If yes, explain below:			

Note: Per the QAPP, field duplicates, rinse blanks, field blanks, MDLs and PQLs are not required for % lipid analyses.

INTRODUCTION

This document is designed to offer the data reviewer guidance in determining the validity of analytical data generated through the USEPA Contract Laboratory Program (CLP) Statement of Work (SOW) ISM01.X Inorganic Superfund Methods (Multi-Media, Multi-Concentration), hereinafter referred to as the ISM01.2 SOW, and any future editorial revisions of ISM01.2. This guidance is somewhat limited in scope and is intended to be used as an aid in the formal technical review process.

The guidelines presented in the document will aid the data reviewer in establishing (a) if data meets the specific technical and QC criteria established in the SOW, and (b) the validity and extent of bias of any data not meeting the specific technical and QC criteria established in the SOW. It must be understood by the reviewer that acceptance of data not meeting technical requirements is based upon many factors, including, but not limited to site-specific technical requirements, the need to facilitate the progress of specific projects, and availability for re-sampling.

The reviewer should note that while this document is to be used as an aid in the formal data review process, other sources of guidance and information, as well as professional judgment, should also be used to determine the ultimate validity of data, especially in those cases where all data does not meet specific technical criteria.

DATA QUALIFIER DEFINITIONS

The following definitions provide brief explanations of the national qualifiers assigned to results in the data review process.

U	The analyte was analyzed for, but was not detected above the level of the reported sample quantitation limit.
J	The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.
J+	The result is an estimated quantity, but the result may be biased high.
J-	The result is an estimated quantity, but the result may be biased low.
R	The data are unusable. The sample results are rejected due to serious deficiencies in meeting Quality Control (QC) criteria. The analyte may or may not be present in the sample.
UJ	The analyte was analyzed for, but was not detected. The reported quantitation limit is approximate and may be inaccurate or imprecise.

DATA PACKAGE INSPECTION

For data obtained through the Contract Laboratory Program (CLP), the EXES Data Manager (EDM) is a useful tool in the data review process. For more information about EDM, please refer to the following Sample Management Office (SMO) website:

<https://epasmoweb.fedcsc.com/help/guides/Submit%20and%20Inspect%20Data%20Quick%20Guide%20%28EXES%29.pdf>

EDM will identify any missing and/or incorrect information in the data package. The CLP laboratory may submit a reconciliation package for any missing items or to correct data. If there are any concerns regarding the data package, contact the CLP Project Officer (CLP PO) from the Region where the samples were taken. For personnel contact information, please refer to the following CLP website:

<http://www.epa.gov/superfund/programs/clp/contacts.htm>

HWSS DATA VALIDATION PROCESS

After downloading the data package from EDM, the data validator will use the recommendations in this SOP as well as their own professional judgment to validate the data.

The data will be saved in the following location, under the appropriate case number folder:

G:\DESADIV\HWSS\DATA VALIDATION

The file naming conventions will consist of

- | | |
|----------------------------------|--------------|
| A. case number | i.e., 12345 |
| B. SDG name | i.e., MBXY12 |
| C. level of validation performed | i.e., S2BVE |

Examples: **12345_MBXY12_S2BVE.xls**

12345_MBXY12_S2BVEM.xls

When data validation is completed, the data package is uploaded for the client to download from the HWSS data delivery website:

<https://epaqpx.rtp.epa.gov/hwssclpdeliverables>

The completed data package includes the Executive Narrative (see Appendix B for template), the Sample Summary Report (see Appendix C for example), and the Electronic Data Deliverable (EDD) (see Appendix D for a list of the column headers included in this document).

PRELIMINARY REVIEW

This document is for the review of analytical data generated through the ISM01.2 SOW and any future editorial revisions of ISM01.2. To use this document effectively, the reviewer should have an understanding of the analytical method and a general overview of the Sample Delivery Group (SDG) or sample Case at hand. The exact number of samples, their assigned numbers, their matrix, and the number of laboratories involved in the analysis are essential information.

It is suggested that an initial review of the data package be performed, taking into consideration all information specific to the sample data package [e.g., Modified Analysis requests, Traffic Report/Chain of Custody (TR/COC) documentation, SDG Narratives, etc.].

The reviewer should also have a copy of the Quality Assurance Project Plan (QAPP) or similar document for the project for which the samples were analyzed. The reviewer should contact the appropriate Regional Contract Laboratory Program Project Officer (CLP PO) to obtain copies of the QAPP and relevant site information. This information is necessary in determining the final usability of the analytical data.

The SDGs or Cases routinely have unique samples that require special attention from the reviewer. These include field blanks and trip blanks, field duplicates, and Performance Evaluation (PE) samples which must be identified in the sampling records. The sampling records (e.g., TR/COC records, field logs, and/or contractor tables) should identify:

1. The Region where the samples were taken, and
2. The complete list of samples with information on:
 - a. Sample matrix;
 - b. Field blanks*;
 - c. Field duplicates*;
 - d. Field spikes*;
 - e. PE samples*;
 - f. Shipping dates;
 - g. Preservatives;
 - h. Types of analysis; and
 - i. Laboratories involved.

* If applicable.

The TR/COC documentation includes sample descriptions and date(s) of sampling. The reviewer must consider lag times between sampling and start of analysis when assessing technical sample holding times.

The laboratory's SDG Narrative is another source of general information. Notable problems with matrices, insufficient sample volume for analysis or reanalysis, samples received in broken containers, preservation, and unusual events should be documented in the SDG Narrative. The reviewer should also inspect any email or telephone/communication logs detailing any discussion of sample or analysis issues between the laboratory, the CLP Sample Management Office (SMO), and the USEPA Region.

Preservation and Holding Times

Action:

NOTE: Apply the action to each sample for which the preservation or holding time criteria was not met.

1. If the pH of aqueous/water metal samples is > 2 at the time of sample receipt, determine if the laboratory adjusted the pH of the sample to ≤ 2 at the time of sample receipt. If not, use professional judgment to qualify the samples based on the pH of the sample and the chemistry of the metal(s) of interest. Qualify results that are \geq Method Detection Limit (MDL) as estimated low (J-), and qualify non-detects as unusable (R).
2. If technical holding times are exceeded, use professional judgment to determine the reliability of the data, based on the magnitude of the additional time compared to the technical requirement and whether the samples were properly preserved. The expected bias would be low. Qualify results that are \geq MDL as estimated low (J-), and qualify non-detects as unusable (R).
3. Due to limited information concerning holding times for soil/sediment, wipe, and filter samples, it is left to the discretion of the data reviewer whether to apply aqueous/water holding time criteria to soil/sediment, wipe, or filter samples. If they are applied, it must be clearly documented in the Data Review Narrative.
4. When the holding times are exceeded, the reviewer should comment in the Data Review Narrative on any possible consequences for the analytical results.
5. When holding times are grossly exceeded, note it for Contract Laboratory Program Project Officer (CLP PO) action.

Table 1. Technical Holding Time Actions for ICP-AES Analysis

Preservation & Holding Time Results	Action for Samples
Aqueous/water metals samples received with pH > 2 and pH not adjusted	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Aqueous/water Metals > 180 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Technical Holding Time exceeded: Soil/sediment, wipe, filter Metals > 180 days	Use professional judgment Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

Calibration

Table 2. Acceptance Criteria for ICVs and CCVs

Analytical Method	Inorganic Analytes	ICV/CCV Low Limit (% of True Value)	ICV/CCV High Limit (% of True Value)
ICP-AES	Metals	90	110

Action:

NOTES: For initial calibrations or ICVs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.
For CCVs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the QC sample and a subsequent technically acceptable analysis of the QC sample in the analytical run.

NOTE: The data validator shall verify the correlation coefficient by calculating it using the standard concentrations and the corresponding instrument response.

1. If the instrument was not calibrated each time the instrument was set up and an ICV standard was not analyzed before field and QC samples, qualify the data as unusable (R). If the instrument was not calibrated with a blank and at least 5 calibration standards, use professional judgment to qualify results that are \geq Method Detection Limit (MDL) as estimated (J), and non-detects as estimated (UJ). If the calibration curve does not include standards at required concentrations (e.g., a blank and at least one at or below CRQL), use professional judgment to qualify results that are \geq MDL as estimated (J), and non-detects as estimated (UJ). If there was not at least one calibration standard at or below the CRQL for each analyte, qualify results that are \geq MDL but $< 2x$ the CRQL as estimated (J), and non-detects as estimated (UJ) and write it in the Contract Problem/Non-Compliance Section of the Data Review Narrative.
2. If the correlation coefficient is < 0.995 , percent differences are outside the $\pm 30\%$ limit, or the y-intercept \geq CRQL, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ). If the correlation coefficient is < 0.990 , qualify results that are \geq MDL as estimated (J) and non-detects as unusable (R).
3. If the ICV or CCV %R falls outside the acceptance windows, use professional judgment to qualify all associated data. If possible, indicate the bias in the review. The following guidelines are recommended:
 - a. If the ICV or CCV %R is $< 75\%$, qualify non-detects as unusable (R). Use professional judgment to qualify all results that are \geq MDL as unusable (R).
 - b. If the ICV or CCV %R falls within the range of 75-89%, qualify sample results that are \geq MDL as estimated low (J-), and qualify non-detects as estimated (UJ).
 - c. If the ICV or CCV %R falls within the range of 111-125%, qualify sample results that are \geq MDL as estimated high (J+).
 - d. If the ICV or CCV %R is within the range of 111-125%, non-detects should not be qualified.

- e. If the ICV or CCV %R is > 125%, use professional judgment to qualify results that are \geq MDL as estimated high (J+). Non-detects should not be qualified.
- f. If the %R is > 160%, qualify all results that are \geq MDL as unusable (R).
- 4. If the laboratory failed to provide adequate calibration information, the Region's designated representative should contact the laboratory and request the necessary information. If the information is not available, the reviewer must use professional judgment to assess the data.
- 5. Note the potential effects on the reported data due to exceeding the calibration criteria in the Data Review Narrative.
- 6. If calibration criteria are grossly exceeded, note this for CLP Project Officer (CLP PO) action.

NOTE: For critical samples, a further in-depth evaluation of the calibration curve may be warranted to determine if additional qualification is necessary.

Table 3. Calibration Actions for ICP-AES Analysis

Calibration Result	Action for Samples
Calibration not performed	Qualify all results as unusable (R)
Calibration incomplete	Use professional judgment Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Not at least one calibration standard at or below the CRQL for each analyte	Qualify results that are \geq MDL but < 2x the CRQL as estimated (J) Qualify non-detects as estimated (UJ)
Correlation coefficient < 0.995; %D outside $\pm 30\%$; y-intercept \geq CRQL	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as estimated (UJ)
Correlation coefficient < 0.990	Qualify results that are \geq MDL as estimated (J) Qualify non-detects as unusable (R)
ICV/CCV %R < 75%	Qualify results that are \geq MDL as unusable (R) Qualify all non-detects as unusable (R)
ICV/CCV %R 75-89%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICV/CCV %R 111-125%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R > 125%	Qualify results that are \geq MDL as estimated high (J+)
ICV/CCV %R > 160%	Qualify results that are \geq MDL as unusable (R)

Calibration/Preparation Blanks

Action:

NOTES: For ICBs that do not meet the technical criteria, apply the action to all samples reported from the analytical run.

For CCBs that do not meet the technical criteria, apply the action to all samples analyzed between a previous technically acceptable analysis of the CCB and a subsequent technically acceptable analysis of the CCB in the analytical run.

For Preparation Blanks that do not meet the technical criteria, apply the action to all samples prepared in the same preparation batch.

NOTES: Convert soil sample result to mg/kg on wet weight basis to compare with the soil preparation result on Form III.

Associated samples are all samples digested with the preparation blank.

1. If the appropriate blanks were not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank (including Preparation Blanks) reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank (including Preparation Blanks) reported with a negative result, whose value is $<$ (-CRQL) qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. Specific “method” actions include:
 - a. If the absolute value of an ICB or a CCB result is $>$ CRQL, the analysis should be terminated. If the analysis was not terminated and the affected samples were not reanalyzed, report non-detects and results that are \geq MDL, but \leq CRQL as CRQL-U. For results that are $>$ CRQL but $<$ Blank Result, report the results at the level of the blank with a “U” qualifier. Use professional judgment to qualify results that are $>$ Blank Result. Note this situation for CLP PO action and record it in the Data Review Narrative.

- b. If the absolute value of the concentration of the Preparation Blank is \leq CRQL, report non-detects and results that are \geq MDL but \leq CRQL as CRQL-U. Use professional judgment to quality results that are $>$ CRQL.
- c. If any analyte concentration in the Preparation Blank is $>$ CRQL, the lowest concentration of that analyte in the associated samples must be 10x the Preparation Blank concentration. Otherwise, all samples associated with that blank with concentrations $<$ 10x the Preparation Blank concentration and $>$ CRQL should be redigested and reanalyzed. Raise the CRQL to the concentration found in the Preparation Blank and report those samples that do not require redigestion (that are \geq MDL but \leq CRQL) as CRQL-U. Note for CLP PO action and record in the Data Review Narrative if the laboratory failed to redigest and reanalyze the affected samples. The reviewer shall then use professional judgment to assess the data.

Table 4. Calibration/Preparation Blank Actions for ICP-AES Analysis

Blank Type	Blank Result	Sample Result	Action for Samples
ICB/CCB	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
ICB/CCB	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ Blank Result	Report at level of Blank Result with a "U"
		$>$ Blank Result	Use professional judgment
ICB/CCB	\leq (-MDL) but \geq (-CRQL)	\geq MDL, or non-detect	Use professional judgment
ICB/CCB	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)
Preparation Blank	$>$ CRQL	\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL but $<$ 10x the Blank Result	Qualify results as estimated high (J+)
		\geq 10x the Blank Result	No action
Preparation Blank	\geq MDL but \leq CRQL	Non-detect	No action
		\geq MDL but \leq CRQL	Report CRQL value with a "U"
		$>$ CRQL	Use professional judgment
Preparation Blank	$<$ (-CRQL)	$<$ 10x the CRQL	Qualify results that are \geq CRQL as estimated low (J-) Qualify non-detects as estimated (UJ)

Inductively Coupled Plasma - Interference Check Sample (ICP-ICS)

Action:

NOTE: For an ICS that does not meet the technical criteria, apply the action to all samples analyzed in the analytical run.

NOTE: The laboratory should have analyzed and reported ICS results for all elements being reported from the analytical run and for all interferents (target and non-target) for these reported elements.

1. The raw data should, but may not, contain results for interferents. If not, the reviewer shall use professional judgment to qualify the data. If the data does contain results for interferents, the reviewer should apply the following actions to samples with concentrations of interferents that are comparable to, or greater than, their respective levels in the ICS:
 - a. If the ICS %R for an analyte or interferent is $> 120\%$ (or greater than the true value + CRQL, as applicable) and the sample results are non-detects, the data should not be qualified.
 - b. If the ICS %R for an analyte or interferent is $> 120\%$ (or greater than the true value + CRQL, as applicable) qualify sample results that are \geq MDL as estimated high (J+). If the ICS %R (or true value) grossly exceeds the limits, use professional judgment to qualify the data.
 - c. If the ICS %R for an analyte or interferent falls within the range of 50-79% (or less than the true value - CRQL, as applicable) qualify sample results that are \geq MDL as estimated low (J-).
 - d. If the ICS recovery for an analyte falls within the range of 50-79% (or less than the true value - CRQL, as applicable), the possibility of false negatives exists. Qualify sample non-detects as estimated (UJ).
 - e. If the ICSAB %R for an analyte or interferent is $< 50\%$, qualify all sample results that are \geq MDL as estimated low (J-) and all sample non-detects as unusable (R).
2. If results that are \geq MDL are observed for analytes that are not present in the ICS solution, the possibility of false positives exists. An evaluation of the associated sample data for the affected elements should be made. For samples with comparable or higher levels of interferents and with analyte concentrations that approximate those levels found in the ICS, qualify sample results that are \geq MDL as estimated high (J+). Non-detects should not be qualified.
3. If negative results are observed for analytes that are not present in the ICS solution, and their absolute value is \geq MDL, the possibility of false negatives in the samples exists. An evaluation of the associated sample data for the affected analytes should be made. For samples with comparable or higher levels of interferents, qualify non-detects for the affected analytes as estimated (UJ), and results that are \geq MDL but $< 10x$ the absolute value of the negative result as estimated low (J-).
4. In general, ICP-AES sample data can be accepted if the concentrations of Al, Ca, Fe, and Mg in the sample are found to be less than or equal to their respective concentrations in

the ICS. If these elements are present at concentrations greater than the level in the ICS, or other elements are present in the sample at > 10 mg/L, the reviewer should investigate the possibility of other interference effects as given in the ICP-AES method or as indicated by the laboratory's interelement correction factors reported on Forms XA-IN and XB-IN for that particular instrument. The analyte concentration equivalents presented in the method should be considered only as estimated values since the exact value of any analytical system is instrument-specific. Therefore, estimate the concentration produced by an interfering element. If the estimate is > 2x the CRQL, and also > 10% of the reported concentration of the affected element, qualify the affected results as estimated (J).

5. If the raw data does not contain results for the interferents, note it in the Data Review Narrative.
6. Actions regarding the interpretation and/or the subsequent qualification of ICP data due to the ICS analytical results can be extremely complex. Use professional judgment to determine the need for the associated sample data to be qualified. The reviewer may need to obtain additional information from the laboratory. All interpretive situations should then be recorded in the Data Review Narrative.
7. If the ICS acceptance criteria are grossly exceeded, note the specifics for CLP PO action.

Table 5. Interference Check Actions for ICP-AES Analysis

Interference Check Sample Results	Action for Samples
ICS %R > 120% (or greater than true value + CRQL)	Qualify results that are \geq MDL as estimated high (J+)
ICS %R 50-79% (or less than true value - CRQL)	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
ICSAB %R < 50%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Potential false positives in field samples with interferents	Qualify results that are \geq MDL as estimated high (J+)
Potential false negatives in field samples with interferents	Qualify results that are \geq MDL but < 10x the (negative value) as estimated low (J-) Qualify non-detects as estimated (UJ)

Laboratory Control Sample (LCS)

Action:

If the LCS criteria are not met, the laboratory performance and method accuracy are in question. Professional judgment should be used to determine if the data should be qualified or rejected. The following guidance is suggested for qualifying sample data associated with an LCS that does not meet the required criteria.

For an LCS that does not meet the technical criteria, apply the action to all samples in the same preparation batch.

1. Aqueous/Water and Soil/Sediment LCS:

- a. If the LCS %R falls within the range of 40-69% (20-49% for Ag and Sb), qualify sample results that are \geq Method Detection Limit (MDL) as estimated low (J-). If the LCS %R is $> 130\%$ (150% for Ag and Sb), qualify sample results that are \geq MDL as estimated high (J+).
- b. If the LCS recovery is $> 130\%$ (150% for Ag and Sb) and the sample results are non-detects, the data should not be qualified.
- c. If the LCS recovery falls within the range of 40-69% (20-49% for Ag and Sb), qualify non-detects as estimated (UJ).
- d. If LCS %R is $< 40\%$ ($< 20\%$ for Ag and Sb), qualify all results that are \geq MDL as estimated low (J-) and all non-detects as unusable (R).
- e. If the LCS %R is $> 150\%$ (170% for Ag and Sb), qualify all affected data (both detects and non-detects) as unusable (R).

2. Wipe/Filter LCS:

- a. If the LCS %R is in the range of 40-69%, qualify sample results that are \geq MDL as estimated low (J-) and qualify non-detects as estimated (UJ).
- b. If the LCS %R is $< 40\%$, qualify all results that are \geq MDL as estimated low (J-) and all non-detects as unusable (R).
- c. If the LCS %R is $> 130\%$ and the sample results are non-detects, do not qualify the data.
- d. If the LCS %R is $> 130\%$, qualify all results \geq MDL as estimated high (J+).

3. If a laboratory fails to analyze an LCS with each SDG, or if a laboratory consistently fails to generate acceptable LCS recoveries, note this for CLP Project Officer (CLP PO) action.

4. Whenever possible, the potential effects on the data due to out-of-control LCS results should be noted in the Data Review Narrative.

Table 6. LCS Actions for ICP-AES Analysis

LCS Result	Action for Samples
Aqueous/Water and Soil/Sediment %R 40-69% (20-49% Ag, Sb)	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
Aqueous/Water and Soil/Sediment %R > 130% (150% Ag, Sb)	Qualify results that are \geq MDL as estimated high (J+)
Aqueous/Water and Soil/Sediment %R < 40% (<20% Ag, Sb)	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)
Aqueous/Water and Soil/Sediment %R > 150% (>170% Ag, Sb)	Qualify all results as unusable (R)
Wipe/Filter %R 40-69%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as estimated (UJ)
Wipe/Filter %R > 130%	Qualify results that are \geq MDL as estimated high (J+)
Wipe/Filter %R < 40%	Qualify results that are \geq MDL as estimated low (J-) Qualify non-detects as unusable (R)

Laboratory Duplicate Sample Analysis

Action:

NOTE: For a duplicate sample analysis that does not meet the technical criteria, apply the action to only the field sample used to prepare the duplicate sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

NOTE: The lab duplicate analysis is not required for wipe and air filter samples. Delete “*” from Form IAs.

If one value is > CRQL and the other value is non-detect, calculate the absolute difference between the value > CRQL and the MDL and use this difference to qualify sample results.

If more than one lab duplicate sample was analyzed for an SDG, then qualify the associated samples based on the worst lab duplicate analysis.

1. If the appropriate number of duplicate samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for CLP Project Officer (CLP PO) action.
2. If the results from a duplicate analysis for a particular analyte fall outside the control limits for > 5x the CRQL, qualify aqueous sample results that are \geq CRQL as estimated (J) if the RPD is between 20% - 100% and as unusable (R) if the RPD is > 100%. Qualify soil/sediment sample results that are \geq CRQL as estimated (J) if the RPD is between 35% - 120% and as unusable (R) if the RPD is > 120%.
3. If the results from a duplicate analysis for a particular analyte fall outside the control limits for \leq 5x the CRQL, qualify those results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
4. If a field blank or PE sample was used for the duplicate sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
5. Note the potential effects on the data due to out-of-control duplicate sample results in the Data Review Narrative.

Table 7. Duplicate Sample Actions for ICP-AES Analysis

Duplicate Sample Results	Action for Samples
<i>Aqueous:</i> Both original sample and duplicate sample > 5x the CRQL and 20% < RPD < 100%	Qualify those results that are \geq CRQL as estimated (J)
<i>Aqueous:</i> Both original sample and duplicate sample > 5x the CRQL and RPD \geq 100%	Qualify those results that are \geq CRQL as unusable (R)
<i>Soil/Sediment:</i> Both original sample and duplicate sample > 5x the CRQL and 35% < RPD < 120%	Qualify those results that are \geq CRQL as estimated (J)
<i>Soil/Sediment:</i> Both original sample and duplicate sample > 5x the CRQL and RPD \geq 120%	Qualify those results that are \geq CRQL as unusable (R)
Original sample or duplicate sample \leq 5x the CRQL (including non-detects) and absolute difference between sample and duplicate > CRQL	Qualify those results that are \geq MDL as estimated (J) and non-detects as estimated (UJ)

Spike Sample Analysis

Action:

- NOTE:** For a Matrix Spike that does not meet the technical criteria, apply the action to only the field sample used to prepare the Matrix Spike sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.
- NOTE:** Post-digestion spikes are not required for Ag.
- NOTE:** The final spike concentrations required for the various target analytes are presented in the methods described in the Statement of Work (SOW).
- NOTE:** When the sample concentration is < Method Detection Limit (MDL), use SR = 0 only for the purpose of calculating the %R. The actual spiked sample results, sample results, and %R (positive or negative) shall still be reported on Forms VA-IN and VB-IN.
- NOTES:** Not required for wipe and filter samples.
Not required for Ca, Mg, K, and Na (both matrices); Al and Fe (soil only).
If more than one spiked sample was analyzed for one SDG, then qualify the associated data based on the worst spiked sample analysis.
Disregard the out of control spike recoveries for analytes whose unspiked concentrations are $\geq 4x$ the spike added.
Delete "N" from Form IAs.
1. If the appropriate number of Matrix Spike samples was not analyzed for each matrix using the correct frequency, use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. Note the situation in the Data Review Narrative, and for Contract Laboratory Program Project Officer (CLP PO) action.
 2. If a field blank or PE sample was used for the spiked sample analysis, note this for CLP PO action. All of the other Quality Control (QC) data must then be carefully checked and professional judgment exercised by the data reviewer when evaluating the data.
 3. If the Matrix Spike recovery does not meet the evaluation criteria and a required post-digestion spike was not performed, note this for CLP PO action.
 4. If the Matrix Spike %R is < 30%, verify that a post-digestion spike was analyzed (if required). If the post-digestion spike %R is < 75% or is not performed, qualify sample results that are \geq MDL as estimated low (J-) and non-detects as unusable (R). If the post-digestion spike %R is $\geq 75%$, qualify sample results that are \geq MDL as estimated (J) and non-detects as estimated (UJ).
 5. If the Matrix Spike %R is 30-74% and the sample results are \geq MDL, verify that a post-digestion spike was analyzed (if required). If the %R for the post-digestion is also < 75% or is not performed, qualify the affected data as estimated low (J-). If the %R for the post-digestion spike is $\geq 75%$, qualify the affected data as estimated (J).

6. If the Matrix Spike %R falls within the range of 30-74% and the sample results are non-detects, qualify the affected data as estimated (UJ).
7. If the Matrix Spike %R is > 125% and the reported sample results are non-detects, the sample data should not be qualified.
8. If the Matrix Spike %R is > 125% and the sample results are \geq MDL, verify that a post-digestion spike was analyzed if required. If the %R for the post-digestion spike is also > 125% or is not performed, qualify the affected data as estimated high (J+). If the %R for the post-digestion spike is \leq 125%, qualify the affected data as estimated (J).
9. Note the potential effects on the data due to out-of-control spiked sample results in the Data Review Narrative.

Table 8. Spike Sample Actions for ICP-AES Analysis

Spike Sample Results	Action for Samples
Matrix Spike %R < 30% Post-digestion spike %R < 75%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R < 30% Post-digestion spike %R \geq 75%	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-digestion Spike %R < 75%	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as estimated (UJ)
Matrix Spike %R 30-74% Post-digestion spike %R \geq 75%	Qualify affected results that are \geq MDL as estimated (J) and affected non-detects as estimated (UJ)
Matrix Spike %R > 125% Post-digestion spike %R > 125%	Qualify affected results that are \geq MDL as estimated high (J+)
Matrix Spike %R > 125% Post-digestion spike %R \leq 125%	Qualify affected results that are \geq MDL as estimated (J)
Matrix Spike %R < 30% No post-digestion spike performed (e.g., not required for Ag)	Qualify affected results that are \geq MDL as estimated low (J-) and affected non-detects as unusable (R)
Matrix Spike %R 30-74% No post-digestion spike performed (e.g., not required for Ag)	Qualify affected results that are \geq MDL as estimated low (J-) and non-detects as estimated (UJ)
Matrix Spike %R > 125% No post-digestion spike performed (e.g., not required for Ag)	Qualify affected results that are \geq MDL as estimated high (J+) Non-detects are not qualified

ICP Serial Dilution

Action:

NOTE: For a serial dilution that does not meet the technical criteria, apply the action to only the field sample used to prepare the serial dilution sample. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

NOTE: Serial dilution analysis is required only when the initial concentration is greater than 50x the MDL.
Delete “E” from Form IAs.

1. If the required %D criteria are not met, qualify affected aqueous results whose raw data are > MDL as estimated (J) if %D is between 10%-100% and qualify as unusable (R) if %D is $\geq 100\%$. Qualify affected soil/sediment results whose raw data are > MDL as estimated (J) if %D is between 15%-120% and qualify as unusable (R) if %D is $\geq 120\%$.
2. If evidence of positive or negative interference is found, use professional judgment to qualify the associated sample data. Note the potential effects on the reported data in the Data Review Narrative.
3. It should be noted for Contract Laboratory Program Project Officer (CLP PO) action and in the Data Review Narrative if a field blank or PE sample was used for the serial dilution analysis.

Table 9. Serial Dilution Actions for ICP-AES Analysis

Serial Dilution Result	Action for Samples
<i>Aqueous:</i> Sample concentration > 50x MDL and $10\% < \%D < 100\%$	Qualify affected results whose raw data are > MDL as estimated (J)
<i>Aqueous:</i> Sample concentration > 50x MDL and $\%D \geq 100\%$	Qualify affected results whose raw data are > MDL as unusable (R)
<i>Soil/Sediment:</i> Sample concentration > 50x MDL and $15\% < \%D < 120\%$	Qualify affected results whose raw data are > MDL as estimated (J)
<i>Soil/Sediment:</i> Sample concentration > 50x MDL and $\%D \geq 120\%$	Qualify affected results whose raw data are > MDL as unusable (R)
Interferences present	Use professional judgment

Field Duplicates

Action:

NOTES: For field duplicates that do not meet the technical criteria, apply the action to only the field sample and its duplicate. If it is clearly stated in the data validation materials that the samples were taken through incremental sampling or some other method guaranteeing the homogeneity of the sample group, then the entire sample group may be qualified.

Check the Sampling Trip Report for the field duplicate pair.

Substitute MDL for CRQL when MDL > CRQL.

Do not calculate RPD when both values are non-detects.

If one value is > the CRQL and the other value is non-detect, calculate the absolute difference between the value > the CRQL and the MDL, and use this criteria to qualify the results.

1. If a field duplicate pair was collected and analyzed, calculate and report the RPD when the sample and its field duplicate values are both $\geq 5x$ the CRQL. Calculate and report the absolute difference when at least one value (sample or duplicate) is $< 5x$ the CRQL.
2. When aqueous sample and duplicate values are both $\geq 5x$ the CRQL, and the RPD is $> 20\%$, qualify the sample and its duplicate as estimated (J).
3. When aqueous sample and/or the duplicate value is $< 5x$ the CRQL, and the absolute difference is $>$ the CRQL, qualify results $>$ the MDL as estimated (J) and non-detects as estimated (UJ).
4. When soil/sediment sample and duplicate values are both $\geq 5x$ the CRQL, and the RPD is $> 50\%$, qualify the sample and its duplicate as estimated (J).
5. When soil/sediment sample and/or the duplicate value is $< 5x$ the CRQL, and the absolute difference is $> 2x$ the CRQL, qualify results $>$ the MDL as estimated (J) and non-detects as estimated (UJ).

Table 10. Field Duplicate Actions for ICP-AES Analysis

Sample Type	Field Duplicate Result	Action for Samples
Aqueous	Sample and its field duplicate $\geq 5x$ the CRQL and RPD $> 20\%$	Qualify sample and its duplicate as estimated (J)
	Sample and/or its field duplicate $< 5x$ the CRQL and absolute difference $>$ the CRQL	Qualify results $>$ the MDL as estimated (J) Qualify non-detects as estimated (UJ)
Soil/Sediment	Sample and its field duplicate $\geq 5x$ the CRQL and RPD $> 50\%$	Qualify sample and its duplicate as estimated (J)
	Sample and/or its field duplicate $< 5x$ the CRQL and absolute difference $> 2x$ the CRQL	Qualify results $>$ the MDL as estimated (J) Qualify non-detects as estimated (UJ)

Field/Rinsate/Trip Blanks

Action:

NOTE: Designate “Field Blank” as such on Form IA.
Field Blank results previously rejected due to other criteria cannot be used to qualify field samples.
Do not use Rinsate Blank associated with soils to qualify water samples and vice versa.
If the MDL is > the CRQL, substitute CRQL with 2x the MDL.

1. If the appropriate blanks were not analyzed with the correct frequency, the data reviewer should use professional judgment to determine if the associated sample data should be qualified. The reviewer may need to obtain additional information from the laboratory. The situation should then be recorded in the Data Review Narrative, and noted for Contract Laboratory Program Project Officer (CLP PO) action.
2. Action regarding unsuitable blank results depends on the circumstances and origin of the blank. The reviewer should note that in instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of contaminant.
3. Some general “technical” review actions include:
 - a. Any blank reported with a negative result, whose value is \leq (-MDL) but \geq (-CRQL), should be carefully evaluated to determine its effect on the sample data. The reviewer shall then use professional judgment to assess the data. For any blank reported with a negative result, whose value is $<$ (-CRQL) qualify results that are \geq CRQL as estimated low (J-) and non-detects as estimated (UJ).
 - b. The blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. In particular, soil/sediment sample results reported on Form I-IN will not be on the same basis (units, dilution) as the calibration blank data reported on Form III-IN. The reviewer may find it easier to work with the raw data.
4. If the absolute value of any analyte in a Field/Rinsate/Trip Blank is > the CRQL, then the CRQL shall be raised to the level in the Field/Rinsate/Trip Blank and the associated sample data below this level shall be reported as CRQL-U.
5. Sample results > the Field/Rinsate/Trip Blank value but < 10x the Field/Rinsate/Trip Blank value shall be qualified as estimated (J).
6. Sample results \geq the MDL but \leq the CRQL shall be reported at the CRQL value with a “U”.

Table 11. Field/Rinsate/Trip Blank Actions for ICP-AES Analysis

Blank Result	Sample Result	Action for Samples
> CRQL	\geq MDL but \leq CRQL	Report CRQL value with a “U”
	> CRQL but < Blank Result	Report at level of Blank Result with a “U”
	> Blank Result but < 10x the Blank Result	Use professional judgment to qualify results as estimated (J)

Linear Ranges

Action:

1. If any sample result was higher than the high linear range for ICP-AES and the sample was not diluted to obtain the result reported on Form I, qualify the affected results \geq MDL as estimated (J).

Percent Solids of Sediments

Action:

1. If the percent solids in sediment for a sample are $< 50\%$, qualify the affected results \geq MDL as estimated (J) and the non-detects as estimated (UJ).

Regional Quality Assurance (QA) and Quality Control (QC)

Action:

Any action must be in accordance with Regional specifications and criteria for acceptable PE sample results. Note any unacceptable PE sample results for Contract Laboratory Program Project Officer (CLP PO) action.

Overall Assessment

Action:

1. Use professional judgment to determine if there is any need to qualify data which were not qualified based on the QC criteria previously discussed.
2. Write a brief Data Review Narrative to give the user an indication of the analytical limitations of the data. Note any discrepancies between the data and the Sample Delivery Group (SDG) Narrative for Contract Laboratory Program Project Officer (CLP PO) action. If sufficient information on the intended use and required quality of the data is available, the reviewer should include an assessment of the data usability within the given context.
3. If any discrepancies are found, the laboratory may be contacted by the Region's designated representative to obtain additional information for resolution. If a discrepancy remains unresolved, the reviewer may determine that qualification of the data is warranted.

Calculations for ICP-AES

Aqueous/Water Samples by Inductively Coupled Plasma-Atomic Emission Spectroscopy (ICP-AES):

The concentrations determined in the digestate are to be reported in units of µg/L:

$$\text{Concentration } \left(\frac{\mu\text{g}}{\text{L}} \right) = C \times \frac{V_f}{V} \times DF$$

Where,

- C = Instrument value in µg/L (The average of all replicate exposures).
V_f = Final digestion volume (mL)
V = Initial aliquot amount (mL)
DF = Dilution Factor

Soil/Sediment Samples by ICP-AES:

The concentrations determined in the digestate are to be reported on the basis of the dry weight of the sample, in units of mg/kg:

$$\text{Concentration (drywt.) } \left(\frac{\text{mg}}{\text{kg}} \right) = C \times \frac{V_f}{W \times S} \times \frac{DF}{1000}$$

Where,

- C = Instrument value in µg/L (The average of all replicate exposures).
V_f = Final digestion volume (mL)
W = Initial aliquot amount (g)
S = % Solids/100 (see Exhibit D of ISM01.2 - Introduction to Analytical Methods, Section 1.6).
DF = Dilution Factor

Adjusted Method Detection Limit (MDL)/Adjusted Contract Required Quantitation Limit (CRQL) Calculation:

To calculate the adjusted MDL or adjusted CRQL for aqueous/water samples, substitute the value of the MDL (µg/L) or CRQL (µg/L) into the “C” term in the equation above. Calculate the adjusted MDL or adjusted CRQL for soil/sediment samples as follows:

$$\text{Adjusted Concentration } \left(\frac{\text{mg}}{\text{kg}} \right) = C \times \frac{W_M}{W \times S} \times \frac{V_f}{V_M} \times DF$$

Where,

- C = MDL or CRQL (mg/kg)
W_M = Minimum method required aliquot amount (g) (1.00 g or 0.50 g)
W = Initial aliquot amount (g)
V_M = Method required final sample digestion volume (mL) (100 mL or 50 mL)
V_f = Final digestion volume (mL)
S = % Solids/100 (see Exhibit D of ISM01.2 - Introduction to Analytical Methods, Section 1.6).
DF = Dilution Factor

Wipe/Filter Mass:

$$Mass (\mu g) = C \times V_f \times \frac{DF}{1000}$$

Where,

- C = Instrument value in $\mu\text{g/L}$ (The average of all replicate exposures).
V_f = Final digestion volume (mL)
DF = Dilution Factor

APPENDIX A: GLOSSARY

Analyte -- The element of interest, ion, or parameter an analysis seeks to determine.

Analytical Services Branch (ASB) -- Directs the Contract Laboratory Program (CLP) from within the Office of Superfund Remediation and Technical Innovation (OSRTI) in the Office of Solid Waste and Emergency Response (OSWER).

Analytical Sample -- Any solution or media introduced into an instrument on which an analysis is performed excluding instrument calibration, Initial Calibration Verification (ICV), Initial Calibration Blank (ICB), Continuing Calibration Verification (CCV), and Continuing Calibration Blank (CCB). Note that the following are all defined as analytical samples: undiluted and diluted samples (USEPA and non-USEPA); Matrix Spike samples; duplicate samples; serial dilution samples, analytical (post-digestion/post-distillation) spike samples; Interference Check Samples (ICSs); Laboratory Control Samples (LCSs); and Preparation Blanks.

Associated Samples -- Any sample related to a particular Quality Control (QC) analysis. For example, for Initial Calibration Verification (ICV), all samples run under the same calibration curve. For duplicates, all Sample Delivery Group (SDG) samples digested/distilled of the same matrix.

Blank -- A sample designed to assess specific sources of contamination. See individual definitions for types of blanks.

Calibration -- The establishment of an analytical curve based on the absorbance, emission intensity, or other measured characteristic of known standards. The calibration standards are to be prepared using the same type of reagents or concentration of acids as used in the sample preparation.

Calibration Blank -- A blank solution containing all of the reagents in the same concentration as those used in the analytical sample preparation. This blank is not subject to the preparation method.

Calibration Curve -- A plot of instrument response versus concentration of standards.

Calibration Standards -- A series of known standard solutions used by the analyst for calibration of the instrument (i.e., preparation of the analytical curve). The solutions may or may not be subjected to the preparation method, but contain the same matrix (i.e., the same amount of reagents and/or preservatives) as the sample preparations to be analyzed.

Case -- A finite, usually predetermined number of samples collected over a given time period from a particular site. Case numbers are assigned by the Sample Management Office (SMO). A Case consists of one or more Sample Delivery Groups (SDGs).

Continuing Calibration Blank (CCB) -- A reagent water sample that is run 2 hours (ICP-AES, ICP-MS) or every hour (Hg, CN) and designed to detect any carryover contamination.

Contract Compliance Screening (CCS) -- A screening of electronic and hardcopy data deliverables for completeness and compliance with the contract. This screening is performed under USEPA direction by the Contract Laboratory Program (CLP) Sample Management Office (SMO) contractor.

Continuing Calibration Verification (CCV) -- A single parameter or multi-parameter standard solution prepared by the analyst and used to verify the stability of the instrument calibration with time, and the instrument performance during the analysis of samples. The CCV can be one of the calibration standards. However, all parameters being measured by the particular system must be

represented in this standard and the standard must have the same matrix (i.e., the same amount of reagents and/or preservatives) as the samples. The CCV should have a concentration in the middle of the calibration range and shall be run every 2 hours (ICP-AES, ICP-MS) or every hour (Hg, CN).

Contract Laboratory Program (CLP) -- Supports the USEPA's Superfund effort by providing a range of state-of-the-art chemical analytical services of known quality. This program is directed by the Analytical Services Branch (ASB) of the Office of Superfund Remediation and Technical Innovation (OSRTI) of USEPA.

Contract Laboratory Program Project Officer (CLP PO) -- The Regional USEPA official responsible for monitoring laboratory performance and/or requesting analytical data or services from a CLP laboratory.

Contract Required Quantitation Limit (CRQL) -- Minimum level of quantitation acceptable under the contract Statement of Work (SOW).

Duplicate -- A second aliquot of a sample that is treated the same as the original sample in order to determine the precision of the method.

Field Blank -- Any sample that is submitted from the field and identified as a blank. A field blank is used to check for cross-contamination during sample collection, sample shipment, and in the laboratory. A field blank includes trip blanks, rinsate blanks, bottle blanks, equipment blanks, preservative blanks, decontamination blanks, etc.

Field Duplicate -- A duplicate sample generated in the field, not in the laboratory.

Holding Time -- The maximum amount of time samples may be held before they are processed.

Contractual -- The maximum amount of time that the Contract Laboratory Program (CLP) laboratory may hold the samples from the sample receipt date until analysis and still be in compliance with the terms of the contract, as specified in the CLP Analytical Services Statement of Work (SOW). These times are the same or less than technical holding times to allow for sample packaging and shipping.

Technical -- The maximum amount of time that samples may be held from the collection date until analysis.

Initial Calibration -- Analysis of analytical standards for a series of different specified concentrations to define the quantitative response, linearity, and dynamic range of the instrument to target analytes.

Initial Calibration Blank (ICB) -- The first blank standard run to confirm the calibration curve.

Initial Calibration Verification (ICV) -- Solution(s) prepared from stock standard solutions, metals, or salts obtained from a source separate from that utilized to prepare the calibration standards. The ICV is used to verify the concentration of the calibration standards and the adequacy of the instrument calibration. The ICV should be traceable to National Institute of Standards and Technology (NIST) or other certified standard sources when USEPA ICV solutions are not available.

Internal Standard -- A non-target element added to a sample at a known concentration after preparation but prior to analysis. Instrument responses to internal standards are monitored as a means of assessing overall instrument performance.

Interference Check Sample (ICS) -- Verifies the contract laboratory's ability to overcome interferences typical of those found in samples.

Laboratory Control Sample (LCS) -- A control sample spiked at known level(s). LCSs are processed using the same sample preparation, reagents, and analytical methods employed for the USEPA samples received.

Matrix -- The predominant material of which the sample to be analyzed is composed. For the purposes of this document, the matrices are aqueous/water, soil/sediment, wipe, and filter.

Matrix Spike -- Introduction of a known concentration of analyte into a sample to provide information about the effect of the sample matrix on the digestion and measurement methodology (also identified as a pre-distillation/digestion spike).

Method Detection Limit (MDL) -- The concentration of a target parameter that, when a sample is processed through the complete method, produces a signal with 99 percent probability that it is different from the blank. For 7 replicates of the sample, the mean value must be 3.14s above the blank, where "s" is the standard deviation of the 7 replicates.

Narrative (SDG Narrative) -- Portion of the data package which includes laboratory, contract, Case, Sample Number identification, and descriptive documentation of any problems encountered in processing the samples, along with corrective action taken and problem resolution.

Office of Solid Waste and Emergency Response (OSWER) -- The USEPA office that provides policy, guidance, and direction for the USEPA's solid waste and emergency response programs, including Superfund.

Percent Difference (%D) -- As used in this document and the Statement of Work (SOW), is used to compare two values. The difference between the two values divided by one of the values.

Performance Evaluation (PE) Sample -- A sample of known composition provided by USEPA for contractor analysis. Used by USEPA to evaluate Contractor performance.

Post Digestion Spike -- The addition of a known amount of standard after digestion or distillation (also identified as an analytical spike).

Preparation Blank -- An analytical control that contains reagent water and reagents, which is carried through the entire preparation and analytical procedure.

Relative Percent Difference (RPD) -- As used in this document and the Statement of Work (SOW) to compare two values, the RPD is based on the mean of the two values, and is reported as an absolute value (i.e., always expressed as a positive number or zero).

Regional Sample Control Center Coordinator (RSCC) -- In USEPA Regions, coordinates sampling efforts and serves as the central point-of-contact for sampling questions and problems. Also assists in coordinating the level of Regional sampling activities to correspond with the monthly projected demand for analytical services.

Relative Standard Deviation (RSD) -- As used in this document and the Statement of Work (SOW), the mean divided by the standard deviation, expressed as a percentage.

Sample -- A single, discrete portion of material to be analyzed, which is contained in single or multiple containers and identified by a unique Sample Number.

Sample Delivery Group (SDG) -- A unit within a sample Case that is used to identify a group of samples for delivery. An SDG is defined by the following, whichever is most frequent:

- a. Each 20 field samples [excluding Performance Evaluation (PE) samples] within a Case; or
- b. Each 7 calendar day period (3 calendar day period for 7-day turnaround) during which field samples in a Case are received (said period beginning with the receipt of the first sample in the SDG).

c. Scheduled at the same level of deliverable.

In addition, all samples and/or sample fractions assigned to an SDG must be scheduled under the same contractual turnaround time. Preliminary Results have **no impact** on defining the SDG. Samples may be assigned to SDGs by matrix (i.e., all soil/sediment samples in one SDG, all aqueous/water samples in another) at the discretion of the laboratory.

Sample Management Office (SMO) -- A contractor-operated facility operated under the SMO contract, awarded and administered by the USEPA. Provides necessary management, operations, and administrative support to the Contract Laboratory Program (CLP).

Serial Dilution -- The dilution of a sample by a factor of five. When corrected by the Dilution Factor (DF), the diluted sample must agree with the original undiluted sample within specified limits. Serial dilution may reflect the influence of interferents [Inductively Coupled Plasma (ICP) only].

Statement of Work (SOW) -- A document which specifies how laboratories analyze samples under a particular Contract Laboratory Program (CLP) analytical program.

Tune -- Analysis of a solution containing a range of isotope masses to establish Inductively Coupled Plasma - Mass Spectrometry (ICP-MS) mass-scale accuracy, mass resolution, and precision prior to calibration.

APPENDIX B: INORGANIC DATA EXECUTIVE NARRATIVE TEMPLATE

	UNITED STATES ENVIRONMENTAL PROTECTION AGENCY REGION 2 DESA/HWSS/HWSS 3899, Woodbridge Avenue, Edison, NJ 08837
<u>EXECUTIVE NARRATIVE</u>	
Case No. : Site:	SDG No. : Laboratory:
QAPP HWSS #: Contractor #:	Number of Samples: Sampling date:
SUMMARY:	
Critical:	Results have an unacceptable level of uncertainty and should not be used for making decisions. Data have been qualified "R" rejected.
Major:	A level of uncertainty exists that may not meet the data quality objectives for the project. A bias is likely to be present in the results. Data have been qualified "J" estimated.
Minor:	The level of uncertainty is acceptable. No significant bias in the data was observed.
<u>Critical Findings:</u>	None
<u>Major Findings:</u>	None
<u>Minor Findings:</u>	None
