1. Introduction

This document presents the Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP) for the proposed sampling of surface sediment (approximately 0 to 6 inches in depth) in the Newark Bay Study Area (NBSA). The sediment collected under this SQT QAPP will be used in the baseline human health and ecological risk assessment (BHHERA) for the following purposes:

1. Analyses to support the SQT
 - Surface sediment chemistry analyses
 - Benthic invertebrate community analyses
 - Laboratory toxicity testing (from which survival and growth metrics of benthic invertebrates will be developed)
2. Additional lines of evidence to support the baseline ecological risk assessment (BERA)
 - Laboratory bioaccumulation tests using invertebrates from which tissue will be collected for chemical analyses
 - Porewater chemical analyses and estimates using passive sampling methods
3. Surface sediment chemistry analyses to support the baseline human health risk assessment (BHHR).

The sediment quality triad (SQT) assessment is an effects-based, weight-of-evidence approach used to evaluate risks to benthic invertebrate communities using three primary lines of evidence: 1) sediment chemistry, 2) sediment toxicity, and 3) benthic invertebrate community metrics. The approach is widely utilized by regulatory agencies, including U.S. Environmental Protection Agency (USEPA) Region 2 and its Partner Agencies¹, as the most appropriate process currently available for assessing potential risks to benthic invertebrates. It is the approach that is being used to assess risks to benthic invertebrates for the Lower Passaic River Restoration Project (LPRRP). For consistency purposes and data comparability, this approach will also be used for the NBSA.

The SQT method incorporates a combination of both quantitative and qualitative analyses to identify potential cause-and-effect relationships between two or more of the components. The approach provides

¹ The Partner Agencies include the U.S. Army Corps of Engineers, New Jersey Department of Environmental Protection, New Jersey Department of Transportation, National Oceanic and Atmospheric Administration (NOAA), and U.S. Fish and Wildlife Service.

information needed to identify degraded conditions and assess impacts of pollution-induced effects on benthic invertebrates. Specifically, the SQT program will involve collecting sediment samples for the following analyses:

- Sediment chemistry (for constituents of potential ecological concern [COPECs] that include a suite of organic and inorganic analytes)
- Sediment toxicity testing in a laboratory with a standard amphipod test species *Leptocheirus plumulosus*
- Benthic invertebrate community analyses (specimens counted and identified from bulk surface sediment samples).

To support the NBSA BERA, two additional lines of evidence or measurement endpoints—laboratory bioaccumulation testing and ex situ porewater passive sampling—have been added to the SQT to help better assess potential chemical-specific toxicological effects and bioaccumulation in benthic invertebrates. The first additional line of evidence added to the SQT program is a bioaccumulation study. The bioaccumulation study will provide data on the direct uptake of various chemical contaminants through the analysis of tissue samples by a representative invertebrate organism—the polychaete worm (*Nereis virens*)—that lives in the sediments of the NBSA. This tissue data will be used to help assess risks to invertebrates, and will also be used to model ingestion of chemicals to upper trophic level wildlife receptors (e.g., birds and mammals). The second additional line of evidence to support the SQT program is the collection of porewater chemistry data using passive samplers deployed in NBSA sediments in the laboratory (i.e., ex situ). Passive samplers will provide information to estimate the dissolved-phase porewater concentrations of some contaminants in NBSA sediment. The dissolved-phase concentration is a useful measure of the amount of a contaminant that is bioavailable to infaunal benthic invertebrates. Passive sampler data collected under this SQT QAPP will support the following objectives of the BHHERA:

1. Estimate the bioavailable fraction of non-polar organic constituents of potential concern (COPCs) (i.e., uptake of dissolved fraction of compounds) in ex situ test sediment. Polyethylene (PE) and polyoxymethylene (POM) passive samplers will be used to add this additional line of evidence to the SQT program for non-polar organic compounds.
2. Estimate the bioavailable fraction of metals/inorganic COPCs (i.e., uptake of dissolved fraction of chemicals) in ex situ test sediment. Diffusion samplers (i.e., dialysis bags) will be used to add this additional line of evidence to the SQT program for inorganic COPCs.
3. Evaluate exposure-response relationships between the biological measures of effect (i.e., laboratory toxicity test and benthic community impairment metrics) of the SQT tests and various measures of chemistry in the NBSA sediment samples (i.e., bulk sediment and porewater passive sampler chemistry).

Finally, sediment samples will also be collected from various shoreline locations where human access is possible/likely to assess the potential human health hazard and risk of chemicals from the dermal contact and incidental ingestion exposure routes. Some of these sediment samples will be the same as those collected from intertidal areas for the SQT, and some will be additional samples from other target shoreline locations. Table 1 provides a summary of the proposed sampling stations and the planned analyses for each station.

The sediment collection event is anticipated to occur in September 2015 as part of sampling activities for the BHHERA. The BHHERA is being conducted as part of Phase III of the Remedial Investigation (RI) for the NBSA. The BHHERA will address the goal to “*Determine the primary human and ecological receptors (endpoints) of PCDDs, PCDFs, PCBs, PAHs, pesticides, and metals contaminated sediments in the NBSA*” (USEPA 2004).

Agreements from the June 28 and 29, 2011 BHHERA Workshop among USEPA, its Partner Agencies, and Tierra Solutions, Inc. (Tierra) resulted in the development of the *Final Newark Bay Study Area Problem Formulation* (Problem Formulation; Tierra 2013). Consistent with the approved Problem Formulation, this SQT QAPP is one of several planning documents developed for tissue and sediment sampling associated with the NBSA BHHERA. The additional planning documents are listed below; these documents provide details regarding the collection of fish, shellfish, and sediment:

- *Technical Memorandum: Proposed Risk Assessment Field Sampling and Analysis Program – Newark Bay Study Area* (ARCADIS 2015; Draft, not approved by USEPA)
- *Reconnaissance Survey Report. Newark Bay Study Area. Baseline Human Health and Ecological Risk Assessment* (Tierra 2015)
- *Crab and Clam Sampling and Analysis QAPP* (Tierra 2014a)
- *Fish Sampling and Analysis QAPP* (Tierra 2014b)

Specifically, the data collected under this SQT QAPP will support the following objectives of the BHHERA:

1. Evaluate whether exposure to site-related COPECs in the NBSA poses unacceptable risks to benthic invertebrate communities.
 - The surface sediment chemistry, porewater chemistry, toxicity, bioaccumulation, and benthic community data collected under this SQT program will be subjected to pairwise and multivariate statistical analyses including (but not necessarily limited to) Spearman or Pearson’s correlation analysis, regression analysis and Principal Components Analysis (PCA). The goal of these analyses is to determine if exposure-response relationships exist in the NBSA between given chemical and/or physical measures in sediment and porewater and toxicological, bioaccumulation

and/or benthic community results/metrics. In addition, by having several measurement endpoints of potential exposure, bioavailability and effects, a weight-of-evidence risk assessment can be developed and likely risk drivers identified for benthic invertebrates in the BERA. While these statistical analyses will be focused on the data collected at the 30 locations within the NBSA, risk findings from these data will be evaluated relative to regional reference risks by comparing the chemistry, toxicity, bioaccumulation, and benthic community data collected under this SQT to appropriate regional datasets. **Tierra anticipates that the regional datasets compiled and used by the CPG for the marine/estuarine portion of the LPRRP SQT will also be used for the NBSA SQT, along with other appropriate reference datasets (e.g., reference data collected for the Newtown Creek Superfund Site).**

2. Evaluate whether the consumption of benthic invertebrates (represented by a laboratory-exposed bioaccumulation test) poses unacceptable risks to fish and wildlife (ecological) receptors.
 - Benthic invertebrate tissue and the co-located sediment data collected under this SQT QAPP will be used in the BERA as input parameters to a food web model, which will estimate dietary exposure of COPECs to upper trophic level ecological receptors (i.e., birds and mammals). Surface sediment data will also be compared to appropriate toxicity benchmarks to qualitatively evaluate potential ecological risks to aquatic plants, fish, and reptiles in the NBSA.
3. Evaluate whether exposure to site-related COPCs in surface sediments in the shoreline Intertidal Areas of the NBSA poses unacceptable risks to human receptors.
 - Data collected from other sampling efforts in the NBSA will also be used (in conjunction with the data collected under this SQT QAPP) to support the BHHRA. For example, fish and shellfish tissue data collected in 2014 and 2015 as part of the tissue sampling effort described in the *Fish Sampling and Analysis QAPP* (Tierra 2014b) and *Crab and Clam Sampling and Analysis QAPP* (Tierra 2014a) will also be used to evaluate potential human health risks from exposure to chemicals in the NBSA.

In the Newark Bay Study Area Problem Formulation Document (Tierra 2013), a conceptual site model (CSM) for Human Health was developed (see Figure 5-1 in Tierra [2013]). Primary sources of contamination include industrial point sources, non-point source runoff, sanitary sewer overflows, CSOs, tributaries, and atmospheric deposition. Secondary contamination sources include sediment and surface water. The CSM identified several potential exposure routes associated with contaminated sediment including dermal contact and incidental ingestion. Furthermore, the CSM identified several complete pathways associated with sediment including recreational users, workers and angler/sportsman. Thus, based on the results from the Crab/Clam and SQT sediment sampling efforts, risks and hazards associated with potential dermal contact and incidental ingestion of sediment will be calculated for recreational users, workers and angler/sportsman. Specifically, USEPA guidance documents will be followed in conducting the BHHRA, and exposure point concentrations (EPCs), exposure parameters, toxicity factors, and risks/hazards, will be presented in the USEPA Risk Assessment Guidance for Superfund (RAGS) Part D

format (USEPA 2001a). Risks and hazards will be calculated and presented separately for oral and dermal exposures, and then summed to determine a total risk and hazard for each chemical, as well as across all chemicals. Reasonable maximum exposure (RME) and central tendency exposure (CTE) risks and hazards will be determined. Target organ-specific hazards will also be presented.

2. Background Information

The NBSA is identified as Newark Bay and portions of the Hackensack River, Kill van Kull, and Arthur Kill. Pursuant to the Administrative Order on Consent under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA Index 02-2004-2010; USEPA 2004), Tierra is conducting an RI/Feasibility Study (FS), on behalf of Occidental Chemical Corporation (the successor to Diamond Shamrock Chemicals Company [formerly known as Diamond Alkali Company]), for the NBSA.

The NBSA is situated within one of the most urbanized and industrialized areas in the United States and is known to be contaminated with a number of chemicals, including, but not limited to, polychlorinated biphenyls (PCBs), polycyclic aromatic hydrocarbons (PAHs), pesticides, herbicides, volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans (PCDDs/PCDFs), and metals (NOAA 1995; USEPA 1998).

The majority of the NBSA shoreline consists of commercial, developed, or abandoned properties. Information from the Reconnaissance Survey in September 2013 indicates that a majority of the shoreline (66%) consists of bulkhead and riprap (Tierra 2015). Residential and recreational areas are located along the waterfront in many of these bulkhead and riprap areas, particularly along the eastern shoreline. Four new residential areas have been proposed for development (Tierra 2013).

Due to the size and complexity of the NBSA, USEPA and Tierra agreed in 2005 that the RI would be implemented in multiple phases. Collectively, the Phase I and Phase II investigations gathered information on NBSA sediment, as described in the *Final Newark Bay Study Area Remedial Investigation Phase I and Phase II Sediment Deposition Report, Revision 1* (Tierra 2011) and the *Final Data Evaluation and Analysis Report, Revision 2* (Tierra 2014c). The Phase III investigation (ongoing) is gathering information for risk assessment purposes and will also include additional sediment sampling to fill RI/FS data gaps. Activities conducted to date under Phase III of the RI have included documents related to the risk assessments (e.g., *Pathways Analysis Report* [USEPA 2006] and *Screening-Level Ecological Risk Assessment for Newark Bay Study Area* [USEPA 2008]) and data collection activities (i.e., crab, clam, fish tissue, and sediment collection). As part of the baseline risk assessment process, the Problem Formulation (Tierra 2013) was developed to document the goals and focus of the baseline risk assessments, and define the questions to be addressed during these evaluations. Consistent with the approved Problem Formulation, several planning documents have been developed for tissue and sediment sampling associated with the NBSA BHHERA, including the *Technical Memorandum: Proposed Risk Assessment Field Sampling and Analysis Program – Newark Bay Study Area* (ARCADIS 2015; Draft, not approved by USEPA), *Reconnaissance Survey Report* (Tierra 2015), *Crab and Clam Sampling and Analysis QAPP* (Tierra 2014a), and *Fish Sampling and Analysis QAPP* (Tierra 2014b). Additional history and background information on the NBSA can be found in the aforementioned documents.

3. Data Use

The data to be collected pursuant to this SQT QAPP will be used for developing the BERA, and to partially support the BHHRA. Benthic invertebrate tissue and the co-located sediment data collected under this SQT QAPP will be used in the BERA as input parameters to a food web model, which will estimate dietary exposure of upper trophic level ecological receptors (i.e., birds and mammals) to COPECs. Surface sediment data will also be compared to appropriate toxicity benchmarks to qualitatively evaluate potential ecological risks to aquatic plants, fish, and reptiles in the NBSA. Data collected from other sampling efforts in the NBSA will also be used (in conjunction with the data collected under this SQT QAPP) to support the BHHRA. For example, fish and shellfish tissue data collected in 2014 and 2015 as part of the tissue sampling effort described in the *Crab and Clam Sampling and Analysis QAPP* (Tierra 2014a) and *Fish Sampling and Analysis QAPP* (Tierra 2014b) will also be used to evaluate potential ecological and human health risks from exposure to chemicals in the NBSA.

The primary sample type that will be collected as part of this sampling event is sediment, which will be collected from locations in the Intertidal Areas, Subtidal Flat areas, and Transitional Slope areas of the NBSA. Surface sediment samples from approximately the top 6 inches (approximately 15 centimeters) will be collected for chemical analysis, toxicity testing, benthic community analyses, and bioaccumulation testing. Sediment will also be collected and shipped to a laboratory for ex situ deployment of passive samplers to collect information about the dissolved-phase porewater concentrations of contaminants in NBSA sediment. The dissolved-phase concentration is a useful measure of the amount of a contaminant that is bioavailable to infaunal benthic invertebrates. Sediment used in the passive sampler test will be collected from the same stations as those identified for the SQT evaluation.

Tissue samples of the polychaete worm (*Nereis virens*) will also be collected as part of the bioaccumulation testing component of the SQT program. At the conclusion of the bioaccumulation test, tissue samples will be analyzed for a subset of chemical parameters² that are evaluated in sediment with the addition of percent lipids.

3.1 Baseline Ecological Risk Assessment

The data described in this SQT QAPP, in conjunction with additional sediment and tissue data collected under the other NBSA risk assessment QAPPs, will collectively support the BERA in evaluating the assessment endpoints for plant, benthic invertebrate, fish, bird, and mammal populations. These assessment endpoints and their associated risk questions were established in the Problem Formulation (Tierra 2013) and are re-stated below (in bold type). The use of the data collected under this SQT QAPP to answer the risk questions is provided for each endpoint.

² See Section 5.4 for additional details regarding chemical analyses for tissue samples.

Assessment Endpoint No. 1 – Survival and/or growth of aquatic plants and maintenance of plants as a food resource and habitat for fish and wildlife.

Sediment chemistry data collected as part of this sampling event will be used as a measurement endpoint to evaluate risks to aquatic plants by answering the following risk question: **Are COPEC concentrations in surface water and sediments from the NBSA greater than benchmarks for the survival and/or growth of aquatic plants?** To do this, measured chemical concentrations in sediment will be compared to available toxicological benchmarks.

Assessment Endpoint No. 2 - Survival, growth, and/or reproduction of invertebrates.

Invertebrates form the base of the food web for fish and other upper-trophic level organisms. The SQT will be the basis for the risk assessment for benthic invertebrates. The SQT incorporates data for sediment (and, in this program, porewater) chemistry, toxicity, and benthic community metrics. Supplemental data from laboratory bioaccumulation testing will also be used to help evaluate risks to benthic invertebrates from the COPECs. The following are specific risk questions that will be addressed from the data collected under this SQT QAPP.

Risk Question: Are invertebrate communities in the NBSA different from those found in water bodies with chemical concentrations consistent with regional reference conditions?

This question will be addressed by comparing community structure data (e.g., total invertebrate abundance, species richness, and abundance of species or specific taxonomic groups) from the NBSA to appropriate regional reference populations using diversity indices, multivariate, and spatial statistical techniques.

Risk Question: Are the COPEC concentrations in sediments from the BAZ greater than benchmarks for the survival, growth, and/or reproduction of invertebrates?

This question will be addressed by comparing chemical concentrations in sediment to toxicological sediment benchmarks from the literature.

Risk Question: Is the survival, growth, and/or reproduction of invertebrates exposed to surface sediments of the NBSA significantly lower than that in reference sediments?

This question will be addressed by evaluating laboratory toxicity test results (survival, growth and reproduction endpoints) developed using NBSA surface sediments with respect to sediment and porewater chemistry and benthic community data, and in comparison to regional reference datasets. The results will also be evaluated using existing regional reference comparisons to support risk management decisions.

Risk Question: Are COPEC concentrations in surface water from the NBSA greater than toxicological benchmarks for the survival, growth, and/or reproduction of invertebrates?

This question will be addressed by comparing previously-collected dissolved chemical concentrations in surface water to toxicological benchmarks from the scientific literature.

Risk Question: Are COPEC residues in invertebrate tissues from the NBSA greater than tissue benchmarks (e.g., critical body residues [CBRs]) for the survival, growth, and/or reproduction of invertebrates?

This question will be addressed by comparing chemical concentrations in laboratory-exposed invertebrates (i.e., polychaete bioaccumulation test) and site-collected invertebrate tissues (clams/crabs) to literature-based toxicity reference values.

Assessment Endpoint Nos. 3 and 4 – Survival, growth, and/or reproduction of reptiles and fish, respectively.

Sediment chemistry data collected as part of this sampling event will be used as a measurement endpoint to evaluate risks to fish and reptiles by answering the following risk question: **Are COPEC concentrations in site sediment at levels that might adversely affect survival, growth, and/or reproduction of reptiles and fish?** To do this, measured chemical concentrations in sediment will be compared to toxicological benchmarks. In addition, invertebrate tissue and sediment chemistry data collected as part of this sampling event will be used as input parameters for a food web model to estimate dietary intakes for fish.

Assessment Endpoint Nos. 5 and 6 – Survival, growth, and/or reproduction of birds and mammals, respectively.

Tissue and sediment chemistry data collected as part of this sampling event will be used as input parameters for a food web model to estimate dietary intakes for select bird and mammal receptors by answering the following risk questions: **Does the daily dose of COPECs received by birds and mammals from consumption of the tissues of prey species and from other media in the NBSA exceed the toxicity reference values (TRVs) for survival, growth, and/or reproduction of birds and mammals? If yes, what are the probabilities of effects of differing magnitude for survival, growth, and/or reproduction of birds and mammals?** To do this, measured chemical concentrations in sediment and benthic invertebrate tissue will be incorporated into the food web model to estimate a daily dietary ingestion of chemicals. This value is then compared to the literature-based TRVs to evaluate potential risks. If potential risks are evident (i.e., the resulting hazard quotient is greater than 1), a probabilistic food web model will be run to estimate the range of possible risks following work plan approval by USEPA.

3.2 Baseline Human Health Risk Assessment

Sediment data collected during this sampling effort will be used to support the BHHRA by assessing the potential human health hazard and risk of chemicals from the dermal contact and incidental ingestion exposure routes. Potential surface sediment exposure scenarios are presented in the human health conceptual site model included in the Problem Formulation (Tierra 2013).

4. Overview of Sampling Design and Locations

4.1 Sampling Stations

Thirty sediment sampling stations proposed for the SQT program were selected using a random, stratified, gridded sample design based on the size (areal extent) of the portion of the zone available for sampling, as described in detail in the *Technical Memorandum: Proposed Risk Assessment Field Sampling and Analysis Program – Newark Bay Study Area* (ARCADIS 2015; Draft, not approved by USEPA). A sediment sample size of 30 was determined, statistically, to be adequate to evaluate relationships among chemical concentrations, amphipod survival, and the various benthic metrics in the NBSA. Using Systat® 12.0, a sample size of 29 was calculated as the minimum size necessary to detect a significant correlation coefficient when the true correlation is 0.5 or greater, with 95% confidence and 80% power. A sample size of 28 was used to collect SQT samples from each sub-basin in the New York/New Jersey (NY/NJ) Harbor Estuary by USEPA's Regional Environmental Monitoring and Assessment Program (REMAP) (USEPA 2003). As such, the proposed sample size of 30 is consistent with that utilized by USEPA in the past within Newark Bay.

For logistical purposes only, the NBSA has been divided into three geographic zones: Newark Bay North, Newark Bay Central, and Newark Bay South. The North, Central, and South zones will not be incorporated into the risk assessment, but will be used to generally check the spatial adequacy of planned sediment sampling. Except in the Intertidal Areas, stations were stratified by geographic zone and randomly located. In each zone, four Intertidal Areas were selected for sampling. As described above, 30 sampling stations have been identified for sampling within the NBSA: 12 stations in Newark Bay North, eight stations in Newark Bay Central, and 10 stations in Newark Bay South. The SQT sampling stations were evaluated with respect to the grain size and total organic carbon (TOC) in the NBSA as shown in Table 3 to ensure that the full range of grain size and TOC characteristics are represented.

In addition, Newark Bay contains several geomorphic areas, three of which are important for sampling considerations: Intertidal Areas, Subtidal Flats, and Transitional Slopes³. While the Navigation and Port Channels may provide overwintering habitat for aquatic organisms, many of these areas are regularly dredged for maintenance purposes. As such, the focus of the proposed sampling program is on the shallower Subtidal Flats, Transitional Slopes, and Intertidal Areas of the NBSA. Areas that were historically dredged but are no longer maintained are also included in the sampling program. These include the former Navigation Channel areas in Newark Bay North and south of Shooters Island. Twelve of the 30 stations are located in the Intertidal Areas, 14 are located in the Subtidal Flats (including three stations located in the

³ Refer to the NBSA Problem Formulation (Tierra 2013) for detailed descriptions of the geographic and geomorphic areas.

formerly dredged area in Newark Bay North), and four stations are located in the Transitional Slopes (Figure 1).

SQT analyses (sediment chemistry, toxicity testing with *L. plumulosus*, and benthic invertebrate community analysis) will be conducted at all 30 selected stations. As additional lines of evidence to support the BERA, porewater chemistry analyses will be conducted at all 30 locations, and bioaccumulation tests will be conducted at a subset of eight stations (two stations in the Subtidal Flats, one station in the Transitional Slopes, and five stations in the Intertidal Areas). Laboratory bioaccumulation tests are being conducted at eight locations to evaluate bioaccumulation to the polychaete worm receptors as another line of evidence for the BERA. The eight sampling locations were selected to coincide with existing SQT sampling locations, so the samples could be obtained from the large bulk sediment composites already being collected for the SQT analyses. The selection of the target sampling locations for the bioaccumulation tests were made primarily in consideration of habitat. The target distribution is to sample 5 intertidal locations, 2 subtidal locations, and one transitional slope location. Since the majority of intertidal habitats in the NBSA are located in the north and south zones, those zones have a higher number of samples than the central zone. The intent is that the distribution of these locations will capture the general range of surface sediment concentrations of COPECs that occur in the NBSA. Table 4 provides a summary of the SQT, BERA, and BHHRA analyses and numbers of stations.

Table 4
Summary of Analyses and Numbers of Stations

Proposed Analysis	Number of Subtidal Flat Stations*	Number of Transitional Slope Stations	Number of Intertidal Stations	Total Number of Sampling Stations

Additional sediment chemistry for BHHRA	--	--	13	13

Notes:

*Includes formerly dredged areas in Newark Bay North.

** 10 of the twelve intertidal stations are being used to support the BHHRA

In support of the BHHRA, and as requested by the USEPA, 23 surface sediment sampling stations were selected from locations near where human-sediment contact could potentially occur. Ten of the 23 sampling stations selected to support the BHHRA overlapped with a sampling location already identified for SQT and BERA purposes; therefore, only 13 additional surface sediment stations have been added. These 13

additional sampling locations will only be analyzed for sediment chemistry. Data collected from these stations will be used to assess the impact of direct human contact with sediment (dermal and incidental sediment ingestion), which could potentially occur during recreational and occupational activities. This additional shoreline sample frequency is roughly equivalent to that used by the Cooperating Parties Group (CPG) in sampling human accessible areas in the LPRRP between 2005 and 2012. Table 2 provides a summary of the Newark Bay shoreline segments with access and corresponding sediment sample numbers from the Crab/Clam QAPP and SQT QAPP that will be used to support the BHHERA.

4.2 Sampling Methodology

Sampling stations will be located using maps and global positioning system (GPS) coordinates. Upon reaching each sampling station, the GPS coordinates will be recorded on the field datasheet. In addition, general observations about the sampling station will be documented, including the presence/absence of vegetation, general substrate appearance and texture, and tidal stage. The time of sample collection at each station will also be recorded. Water quality will be measured in the field during sediment collection using a multi-parameter water quality meter. Water quality parameters that will be measured include pH, temperature, conductivity, salinity, and dissolved oxygen.

Surficial sediment will be collected from each sampling station using a grab sampling device appropriate for the water depth and substrate type. A series of grab samples will be collected at each station to obtain sufficient sediment mass to perform all chemical and toxicological analyses. An initial single sediment grab sample will be collected from the center area of each sampling station for analysis of volatiles, AVS/SEM, and TEPH-purgeables, as described in Standard Operating Procedure (SOP) No. 6 (Appendix B). This sample will not be composited/homogenized with the rest of the collected sediment.

Bulk sediment samples will be collected from each location for the remaining sediment chemistry analyses, sediment toxicity testing, bioaccumulation testing, and ex situ porewater passive sampling. Prior to sample preparation, the bulk sediment samples from each sampling station will be homogenized in a large stainless steel bucket with a decontaminated mechanical mixer until textural, color, and moisture homogeneity is achieved. The mechanical mixer will be decontaminated between sampling stations as described in SOP No. 3 – Decontamination (Appendix B). Once homogenized, the appropriate amount of sediment for each analysis will be placed in appropriately labeled sample containers. Sample containers for toxicity and bioaccumulation testing will be lined with a plastic bag prior to filling with sediment. Once filled, all of the air will be squeezed out (to minimize oxidation-reduction potential [ORP] and dissolved oxygen [DO] changes), and then the bucket will be sealed in preparation for shipment. For ex situ porewater passive sampling, a 4-gallon bulk sediment sample will be collected from each sampling location, homogenized (as described above), and placed in a 5-gallon bucket. The remaining space in each bucket will be filled with site water. Additionally, a 1-L bottle will be filled with the 0.8L aliquot of homogenized sediment in the field during sample processing and prior to shipment to UMBC. This sample will not be taken from the 5-gallon bucket at UMBC. This will minimize further disturbance of the sediments in the 5-gallon buckets where attempts to recreate redox conditions are being conducted. Finally, a minimum of two 5-gallon buckets of site water also will be sent to UMBC for use in the 1-L bottle test chambers, as well as for topping off any test chambers in

the event water is lost by evaporation during the experiment. Samples for chemistry analysis will be stored on wet ice for shipment to the designated testing laboratories. Samples for toxicity testing, bioaccumulation testing, and ex situ porewater passive sampling will be refrigerated until shipment to the designated testing laboratories.

Finally, three discrete grab samples will be collected from each station for benthic invertebrate community analysis. Each grab sample will be sieved immediately and independently after collection, as described in SOP No. 6 (Appendix B). Contents of each sieved grab sample will be placed in appropriately labeled sample containers, preserved with isopropyl alcohol, and sealed as described in SOP No. 5 (Appendix B). These samples will not be homogenized.

5. Analysis

The analyte list for sediment, tissue, and porewater passive samplers collected under this SQT QAPP is based on available data collected under the following programs:

- Newark Bay Phase I and II Sediment Investigations (Tierra 2014c, 2011)
- LPRRP RI/FS CPG Fish and Decapod Crustacean Tissue Collection (Windward 2009a)
- LPRRP RI/FS CPG Surface Sediment and Benthic Invertebrate Sampling Program (Windward 2009b).

Table 5 provides a summary of the chemical analyses planned for each matrix. Additional details are provided below.

Table 5

5.1 Sediment Chemistry

The chemical analyses planned for surface sediment samples collected in support of the SQT program and the BHHRA include all chemical analyses performed under the CPG LPRRP and Phases I and II of the Newark Bay Sediment Investigations. Table 6 provides a comparison of the chemical groups proposed for sediment analysis in the NBSA under this SQT QAPP and the analyses conducted under the LPRRP and NBSA Phase I/II Sediment Investigation. Target chemical groups and individual analytes for sediment analysis are provided in Worksheet No. 15-2.

5.2 Sediment Toxicity Testing

Two toxicity tests will be conducted using *Leptocheirus plumulosus*: a short-term 10-day exposure, and a longer-term 28-day exposure. Having two tests of the same species at different exposure durations strengthens the overall line of evidence for the sediment toxicity endpoint. It will allow an evaluation as to whether exposure duration may affect the results of the test in terms of mortality or growth of the test organism. To perform this comparison, both tests are conducted at all 30 SQT stations.

The 10-day toxicity test for survival will be conducted on the sediment samples collected from the 30 SQT stations proposed for the NBSA using USEPA (1994) *Methods for Assessing the Toxicity of Sediment-associated Contaminants with Estuarine and Marine Amphipods* (EPA/600/R-94/025) and ASTM International (ASTM 2008) *Standard Guide for Measuring the Toxicity of Sediment-Associated Contaminants with Marine and Estuarine Amphipods* (E-1267-03). The 28-day toxicity study for survival, growth, and reproduction will also be conducted on sediment samples from the 30 SQT stations proposed for the NBSA using USEPA (2001) *Methods for Assessing the Chronic Toxicity of Marine and Estuarine Sediment-associated Contaminants with the Amphipod, Leptocheirus plumulosus* (EPA/600/R-01/0250). For both toxicity tests, a 7-day stabilization period will be instituted prior to the introduction of the test organisms. Additionally, ORP will be monitored and recorded throughout the equilibration and the test duration (SOP L-45). Five test chambers will be prepared from each of five sampling stations to monitor ORP. Daily ORP measurements will be recorded.

5.3 Sediment Benthic Community Analysis

Benthic communities will be analyzed by identifying and enumerating the benthic invertebrates from sediment grab samples collected at the 30 SQT locations. The benthic community samples will be identified to the lowest practicable taxonomic level and, in accordance with other surveys in the NY/NJ Harbor Estuary

(Weisberg et al. 1997), various benthic metrics, including, but not limited to, species richness, abundance, and diversity, will be calculated at each SQT station. A benthic index of biotic integrity assessment will also be conducted using these data following the approach by the USEPA REMAP (USEPA 1998).

5.4 Bioaccumulation Study

A bioaccumulation study will be conducted on NBSA sediment to provide data on the direct uptake of various chemical contaminants by a key representative invertebrate organism that lives in the sediments of the NBSA, the polychaete worm (*N. virens*). These data will be used to help assess risks to invertebrates, and the movement of contaminants in sediments into the base of the food web for trophic transfer to higher organisms. As part of bioaccumulation testing, tissue samples of the polychaete worm will be submitted for analytical chemistry analysis, as discussed further below. A statistical evaluation will then be conducted to determine if there is a correlation between contaminant concentrations in sediments and polychaetes. A site-specific biota-sediment accumulation factor will be calculated if statistical evaluations indicate a relationship between co-located sediment and tissue data.

A 28-day bioaccumulation study will be conducted for the NBSA using the polychaete worm (*N. virens*), following ASTM (2010) E1688 *Standard Guide for Determination of the Bioaccumulation of Sediment-associated Contaminants by Benthic Invertebrates*. For the bioaccumulation test, a 7-day stabilization period will be instituted prior to the introduction of the test organisms. Additionally, ORP will be monitored and recorded throughout the equilibration and the test duration (SOP L-45). Five test chambers will be prepared from each of five sampling stations to monitor ORP. Daily ORP measurements will be recorded. Laboratory bioaccumulation testing will be conducted on sediments collected from a subset of eight of the SQT stations: five Intertidal Area stations, two Subtidal Flat stations, and one Transitional Slope station (Figure 1). Bioaccumulation studies are not necessary at all SQT stations because actual tissue data (i.e., softshell clams) have been collected at many of the stations and will provide a direct measure of bioaccumulation in benthic organisms for the BERA.

Table 7 provides a comparison of the target chemical groups for tissue analysis under the CPG LPRRP and the targeted chemical groups proposed for polychaete tissue analysis in the NBSA under this SQT QAPP. These chemical groups are consistent with the parameters analyzed in tissue under the CPG LPRRP. Worksheet No. 15-3 lists the specific analytes in each of these chemical classes that will be analyzed.

Table 7
Comparison of Chemical Groups for Tissue Analysis

Analyte Group	LPRRP	Proposed for NBSA Phase III Investigation
PCDDs/PCDFs	X	X
Congener PCBs	X	X
Aroclor PCBs	X	X
Metals	X	X

Analyte Group	LPRRP	Proposed for NBSA Phase III Investigation
Mercury	X	X
Methylmercury	X	X
SVOCs (including phthalates)	X	X
SVOC SIM (including alkylated)	X	X
Percent Lipids	X	X
Percent Moisture	X	X
Pesticides	X	X
Herbicides		
Butyltins	X	X

Note: X = the analysis was conducted in previous tissue investigations or is planned as part of this SQT QAPP

Although VOCs, hexavalent chromium, and herbicides are identified as possible COPECs/COPCs, VOCs and hexavalent chromium were not identified as bioaccumulative chemicals by USEPA (2000). Therefore, VOCs and hexavalent chromium will not be analyzed in tissue samples. Herbicides are not included for analysis in tissue for the following reasons: 1) there are no published methods for herbicides in tissue, 2) herbicides are infrequently detected in recent studies, and 3) the bioaccumulation potential is low.

5.5 Porewater

Porewater samples will be analyzed for PCDDs/PCDFs, congener PCBs, metals, mercury, methylmercury, SVOC SIM (including alkylated), pesticides, DOC, ammonia, and total sulfide. Table 8 provides a summary of the target chemical groups and passive sampling approach for porewater analysis. Target chemical groups and individual analytes for porewater analysis are provided in Worksheet No. 15-4. Porewater was not collected/analyzed in the LPRRP; therefore, there is no comparison between the program analytes.

Table 8
Chemical Groups for Porewater Analysis

Analyte Group	Proposed for NBSA Phase III Investigation
PCDDs/PCDFs	X
Congener PCBs	X
Metals	X
Mercury	X
Methylmercury	X
SVOC SIM (including alkylated)	X
Pesticides	X
Dissolved Organic Carbon	X
Ammonia	X

Analyte Group	Proposed for NBSA Phase III Investigation
Total Sulfide	X

Note: X = the analysis is planned as part of this SQT QAPP

Porewater measurements will be conducted in the laboratory using passive sampling techniques. From each sampling location, a 4-gallon bulk sediment sample will be collected, homogenized, and placed in a 5-gallon bucket. The remaining space in each bucket will be filled with site water. Sealed buckets will be transported to the Environmental Engineering laboratories at UMBC.

The porewater analysis approach for each class of compounds is described below.

5.5.1 Hydrophobic Organic Compounds (PCBs, SVOC SIM, PCDDs/PCDFs)

Passive sampling of the porewater phase has emerged as an alternative technique to assess freely dissolved concentrations of hydrophobic chemicals without interference from colloidal particles. Common passive sampling polymers that have been used include polyethylene (PE) and polyoxymethylene (POM). For this work, a recently published guidance document on passive sampling (Ghosh et al. 2014) will be followed to measure equilibrium porewater concentrations for the selected hydrophobic organic compounds in sediments.

For hydrophobic organics, a 0.8-L sediment sub-sample will be placed in a 1-L glass bottle with the remaining volume in the 1-L bottle filled with site water, creating a sediment slurry. Passive equilibrium sampling for hydrophobic organics will be conducted in the 1-L bottle by placing PE and POM passive samplers in the bottle and allowing the sediment slurry to mix via tumbling for one month. Before contact with the sediment slurry, each passive sampler will be cleaned and impregnated with selected performance reference compounds that will allow the assessment of the extent of equilibrium achieved during the contact period. After the period of contact, the passive samplers will be removed from the sediment slurry and cleaned to remove any attached sediment particles. The passive samplers will be shipped to the analytical laboratory for extraction in hexane and acetone. A schematic of the proposed laboratory exposure system is shown below.

Passive sampler
for organics

5.5.2 Pesticides

Porewater concentration of all pesticides will be measured using PE passive sampling. For some of the pesticides (i.e., DDX), partition constants are available in the literature (e.g., Fernandez et al. 2014) and will be used to estimate the freely dissolved porewater concentrations. For the remaining pesticides where polymer partition coefficients (K_{pe}) are not available, the freely dissolved porewater concentrations will be estimated based on a correlation between the known pesticide partitioning constant and compound log K_{ow} . Performance reference compounds used for PCBs will also be used for corrections of non-equilibrium for all pesticides.

5.5.3 Metals and Other Inorganics

Most dissolved inorganics and metals are extremely redox sensitive, therefore measurement of these constituents in samples shipped to the laboratory is challenging and needs to be performed with caution. Sediment handling during sampling and laboratory experiments can oxidize contaminants and alter bioavailability. For example, volatile sulfides can be oxidized in air, increasing the availability of sulfide-bound metals. To minimize artifacts caused by sediment handling and redox changes, there will be minimal handling of the sediments in the laboratory. The 5-gallon buckets of sediment with overlying site water will be allowed to incubate in the dark for a period of 2 weeks to allow the sediment redox conditions to redevelop.

Dialysis samplers will be used for the sampling of metals and other inorganics in porewater, as described in Vroblecky and Pravecek (2002). Ex-situ laboratory equilibrium studies will be conducted in 5-gallon buckets (one bucket for each sampling location). After the buckets have been allowed to reconsolidate in the laboratory for 2 weeks, dialysis samplers containing clean water with matching site salinity will be placed in each bucket to evaluate metals and other ionized species in porewater.

The dialysis samplers will consist of a perforated support tube made of plastic enclosed within a tied off dialysis bag. After cleaning, the dialysis bags will be filled with DI water purged with nitrogen to remove oxygen and adjusted to site salinity with Instant Ocean salt (or similar). Multiple dialysis devices will be placed within the top 12-inches of sediment in each bucket to allow the final collection of 1.5 L of dialyzed porewater. The dialysis samplers will be allowed to equilibrate in the sediments for a period of 2 weeks. After removal, the water sample within the dialysis chambers will be emptied into clean bottles without headspace and preserved for shipping to the analytical laboratory. A schematic of the proposed laboratory exposure system for metals and other inorganics is shown below.

5.5.4 Chemical Analysis and Reporting

Chemical analyses will be performed at analytical laboratory(ies) identified in this QAPP. The analytical laboratory(ies) will report the concentrations of organic compounds in the extract from the passive samplers, which will then be corrected using site-specific partition constants. Passive sampler partition constants will be used, as described in Ghosh et al. (2014), to calculate the aqueous concentration in equilibrium with the sediment. Site-specific partition constants for the compounds can then be calculated by dividing the sediment phase concentration with the equilibrium aqueous phase concentration. Because some of the strongly hydrophobic compounds will not achieve equilibrium during the period of contact due to slow mass transfer, a mathematical correction using performance reference compounds (PRCs) will be performed to calculate the true equilibrium concentrations (Fernandez et al. 2009).

The analytical laboratory(ies) will report the concentrations of inorganic compounds in the water sample collected from the dialysis bags directly; therefore, correction with partition constants is not needed.

6. Document Organization

This document was prepared using the Uniform Federal Policy for Quality Assurance Project Plans guidance (USEPA et al. 2005). Worksheet No. 2 identifies the location of each element of this SQT QAPP. A brief summary of the information provided in this document is presented below.

Information about personnel and project organization related specifically to this SQT QAPP, including personnel responsibilities, qualifications, and special training, as well as project organization, distribution, and communications pathways, are presented in Worksheet Nos. 3 through 8. Worksheet No. 9 presents a summary of the scoping sessions conducted for the development of this SQT QAPP.

The problem definition, project quality objectives, a summary of project tasks, and the project schedule and timeline for this SQT QAPP are summarized in Worksheet Nos. 10, 11, 14, and 16, respectively. Worksheet No. 13 provides a summary of secondary data that may be used for the completion of this SQT QAPP. The field sampling design, rationale, and a list of proposed sampling locations are provided in Worksheet Nos. 17 and 18.

Information related to laboratory analyses, including performance criteria; reference limits and evaluations; analytical SOP requirements; SOP references; instrument calibration; instrument and equipment maintenance, testing, and inspection; quality control samples; and analytical services are presented in Worksheet Nos. 12, 15, 19, 23, 24, 25, 28, and 30, respectively.

Field quality control samples are summarized in Worksheet No. 20. Field sampling SOPs are presented in Appendix B of this document, and the location of each SOP is identified in Worksheet No. 21. Procedures for the calibration and maintenance of field equipment are presented in Worksheet No. 22. Field sample handling and custody procedures are provided in Worksheet Nos. 26 and 27, respectively.

A summary of the documents and records associated with this SQT QAPP, from the field sampling effort to delivery of the data report, is presented in Worksheet No. 29. Internal and external assessments of the field activities, map preparation, laboratory analytical method compliance, data usability, and document review are described in Worksheet No. 31. Types of findings and corrective action responses are provided in Worksheet No. 32. A summary of quality assurance management reports for this SQT QAPP is provided in Worksheet No. 33. Verification of field sampling data, validation of laboratory analytical data, and an assessment of data usability are presented in Worksheet Nos. 34 through 37.

Notes:

NA = not applicable

x = analysis planned for this location

* = proposed SQT location is co-located with clam/sediment sampling location from September 2014

** = clams were not found at these locations, but they were investigated

Notes:

1. Crab/Clam sampling stations 124 and 132B have not been included as they are not within the boundaries of shoreline segments identified as having human access in the NBSA shoreline access characterization map (Figure B6) of the NBSA Problem Formulation (June 2013).

^a Identified in Table B1 of the NBSA Problem Formulation (June 2013).

^b Identified in Figure 2-1 of the NJDEP Permit Submittal document dated February 26, 2015.

^c Identified in Figure 1 of the NBSA Sediment Quality Triad and Porewater Sampling and Analysis (August 2015).

^d Crab/Clam samples 123A and 123B, and SQT QAPP sample 136 provide data for the accessible shoreline areas near The Thomas M. Gerrity Athletic Complex.

^e SQT QAPP sample 168 provides data for the recreational area near the NE corner of the Bay (just north of the parks in Bayonne).

^f SQT QAPP sample 169 provides data for accessible shoreline areas near Richard A. Rutkowski Park.

^g SQT QAPP sample 142 provides data for the beach-like area near Bayonne High School.

^h SQT QAPP sample 170 is proposed to be collected near the northern shoreline area of the trailer park. As seen in Appendix B-7 of the NBSA Reconnaissance Survey Report (April 2015) and in Google Earth images of the trailer park shoreline it is dominated by riprap. SQT QAPP sample 170 is proposed to be collected in an area that is most accessible by humans.

ⁱ SQT QAPP sample 146 will not be used for the BHHRA due to its location on a transitional slope; a new sample closer to the shoreline will be added.

* = The sample location may not be within the exact segment boundary, however it is within a reasonable distance to be considered relevant and useful

(CC) = Community Commercial

(I) = Industrial

(KA) = Kapkowski Road Redevelopment Area

(M) = Manufacturing

(MRC) = Manufacturing, Research, Commercial

(R) = Residential

(RA) = Redevelopment Area

(WDD) = Waterfront Development District

--	--	NB02SED113	NEWARK BAY SOUTH	NAVIGATION CHANNEL	0	0.5	14.63	22,300
--	--	NB02SED115	NEWARK BAY SOUTH	NAVIGATION CHANNEL	0	0.5	45.95	15,500
--	--	NB02SED118	NEWARK BAY SOUTH	NAVIGATION CHANNEL	0	0.5	15.65	28,800
--	--	NB02SED120	NEWARK BAY SOUTH	NAVIGATION CHANNEL	0	0.5	24.95	42,300

Notes:

1. Duplicate values are shown in brackets.
2. Proposed SQT sampling locations 142, 143, 145, 147, 148, 152, 156, 158, 159, 160, 165-168, and 170-176 do not have corresponding Newark Bay Phase I/II sampling locations.

D50 (µm) = Median Grain size in micrometers

-- = no corresponding proposed SQT sampling location

ft = feet

ppm = parts per million

Worksheets

QAPP Worksheet #1 (UFP-QAPP Manual Section 2.1): Title and Approval Page

Document Title: Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP)

Lead Organization: Tierra Solutions, Inc. on behalf of Occidental Chemical Corporation

Preparer's Name and Organizational Affiliation: Ms. Carlie Thompson, Tierra Solutions, Inc.

Preparer's Address, Telephone Number, and Email Address:

Tierra Solutions, Inc.
Two Tower Center Boulevard, Floor 10
East Brunswick, New Jersey 08816
Phone: 732.246.5849
E-mail: cthompson@tierrasolutionsinc.com

Preparation Date (Month/Day/Year): August 26, 2015

Lead Organization's Facility Coordinator:

Carlie Thompson/Tierra Solutions, Inc.

Quality Assurance Coordinator:

Angela Gatchie/Field & Technical Services

Investigative Organization's Principal-in-Charge:

Alain Hebert/ARCADIS U.S., Inc.

Investigative Organization's Project Task Manager:

Jamie Combes/ARCADIS U.S., Inc.

Investigative Organization's Project Quality Assurance Officer:

Alain Hebert/ARCADIS U.S., Inc.

QAPP Worksheet #2 (UFP-QAPP Manual Section 2.2.4): QAPP Identifying Information

Site Name/Project Name: Newark Bay Study Area/Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP)

Site Location: Newark Bay, New Jersey
Site Number/Code: CERCLA Document No. 02-2004-2010
Operable Unit: 003
Contractor Name: ARCADIS U.S., Inc.
Contractor Number: Not Applicable (NA)
Contract Title: NA
Work Assignment Number: NA

1. Identify guidance used to prepare QAPP:
 - USEPA, USDOD, and USDOE. 2005. Intergovernmental Data Quality Task Force. Uniform Federal Policy for Quality Assurance Project Plans. Evaluating, Assessing, and Documenting Environmental Data Collection and Use Programs. Part 1: UFP-QAPP Manual. USEPA 505-B-04-900A. Final Version 1. March.
2. Identify regulatory program: CERCLA.
3. Identify approval entity: USEPA Region 2
4. Indicate whether the QAPP is a generic or a project-specific QAPP. (circle one)
5. List dates of scoping sessions that were held:
 - February 22, 2013
 - July 22 and 29, 2013
 - March 31, 2014
 - May 6, 2014
 - October 15, 2014
 - December 10, 2014
 - January 14, 2015
 - February 2, 2015
6. List dates and titles of QAPP and Field Sampling Plan (FSP) documents written for previous site work, if applicable:

Tierra. 2005. Newark Bay Study Area Remedial Investigation Work Plan. Sediment Sampling and Source Identification Program, Newark Bay, New Jersey. Phase I. Revision 1. Volumes 1-3. September.

Tierra. 2007. Newark Bay Study Area Remedial Investigation Work Plan. Sediment Sampling and Source Identification Program, Newark Bay, New Jersey. Phase II. Revision 2, Amendment 1. November.

QAPP Worksheet #2 (UFP-QAPP Manual Section 2.2.4): QAPP Identifying Information

Tierra. 2011. Waste Characterization Quality Assurance Project Plan. Diamond Alkali Superfund Site, Operable Unit 1/CERCLA Non-Time-Critical Removal Action – Lower Passaic River Study Area and Newark Bay Study Area. Revision 1. December.
Tierra. 2012. Quality Assurance Project Plan for Newark Bay Study Area: Multi-beam and Single-beam Bathymetric Survey. Revision 1. December.
Tierra. 2013. Newark Bay Study Area Reconnaissance Survey Work Plan. Baseline Human Health and Ecological Risk Assessment. September.
Tierra. 2014. Newark Bay Study Area Crab and Clam Sampling and Analysis Quality Assurance Project Plan. Tierra Solutions, Inc. East Brunswick, New Jersey. Revision 3a. August.
Tierra. 2014. Newark Bay Study Area Fish Sampling and Analysis Quality Assurance Project Plan. Tierra Solutions, Inc. East Brunswick, New Jersey. Revision 2. October.

Additionally, the following QAPPs and documents were written for similar work on an adjacent site (Lower Passaic River) and were used to guide the scope of this QAPP:

Tierra Solutions. 1999. Passaic River Study Area Ecological Sampling Plan. Quality Assurance Project Plan. Volume 2 of 6. Tierra Solutions, Inc. Newark, New Jersey.
Windward. 2009a. Lower Passaic River Restoration Project. Quality Assurance Project Plan. Fish and Decapod Crustacean Tissue Collection for Chemical Analysis and Fish Community Survey. Final. August 6.
Windward. 2009b. Lower Passaic River Restoration Project. Quality Assurance Project Plan. Surface Sediment Chemical Analyses and Benthic Invertebrate Toxicity and Bioaccumulation and Tissue Testing. Final. October 8.
Windward. 2011. 2009 Fish and Blue Crab Tissue Chemistry Data for the Lower Passaic River Study Area. Prepared for Cooperating Parties Group, Newark, NJ. September.

- List organizational partners (stakeholders) and connection with lead organization:

This work will be performed under the requirements of the Administrative Order on Consent (CERCLA-02-2004-2010) (USEPA 2004) for the NBSA, with oversight conducted by USEPA and its partner agencies (NJDEP, NOAA, USFWS, USACE, NJDOT). Tierra (acting as Facility Coordinator), has engaged ARCADIS U.S., Inc. to prepare this document on its behalf.

- List data users: see Worksheet #11.

- If any required QAPP elements and required information are not applicable to the project, then circle the omitted QAPP elements and required information on the attached table. Provide an explanation for their exclusion below:

Upal Ghosh	Project Manager	University of Maryland Baltimore County	Laboratory Project Manager	Ph.D. Civil and Environmental Engineering/22 years

Note: ^a Resumes of all individuals are available upon request.

QAPP Worksheet #8 (UFP-QAPP Manual Section 2.4.4): Special Personnel Training Requirements Table

All field personnel assigned to the site must have successfully completed 40 hours of training for hazardous site work in accordance with Occupational Safety and Health Administration (OSHA) 29 Code of Federal Regulations (CFR) 1910.120(e)(3) and be current with their 8-hour refresher training in accordance with OSHA 29 CFR 1910.120(e)(8). Documentation of OSHA training is required prior to personnel being permitted to work on site.

Personnel managing or supervising work on site will also have successfully completed 8 hours of Manager/Supervisor Training in accordance with OSHA 29 CFR 1910.120(e)(4).

Personnel assigned to the site must be enrolled in a medical surveillance program that meets the requirements of OSHA 29 CFR 1910.120(f). Personnel must have successfully passed a periodic occupational physical and be medically cleared to work on a hazardous waste site and capable of wearing appropriate personal protective equipment. For employees potentially exposed more than 30 days per year, the frequency of periodic examinations will be annual. For employees potentially exposed less than 30 days per year, the frequency for periodic examinations will be once every 24 months.

It is the responsibility of the site worker's employer to provide their employees with the required training and medical monitoring prior to assigning them to work at the site. Each employer will be responsible for providing documentation of training and monitoring to the Field Supervisor prior to sending their employees to the site to work.

Additional health and safety information and records documentation information are detailed in the site-specific Health and Safety Plan.

QAPP Worksheet #9 (UFP-QAPP Manual Section 2.5.1): Project Scoping Session Participants Sheet, February 22, 2013

Project Name: Sediment Quality Triad Sampling Projected Date(s) of Sampling: Fall 2013 Project Managers: Carlie Thompson (Tierra)/Melissa Beauchemin (ARCADIS)			Site Name: NBSA Site Location: Newark Bay, New Jersey	
Date of Session: February 22, 2013 Scoping Session Purpose: To discuss measurement endpoints for the upcoming baseline ecological risk assessment of the NBSA				
Name	Affiliation	Phone #	Email Address	Project Role

Tim Iannuzzi	ARCADIS	410-991-9754	tim.iannuzzi@arcadis-us.com	Technical Expert
Comments/Decisions: A summary of the Meeting Minutes as they pertain to this QAPP is provided below: <u>Assessment Endpoint 2: Invertebrates</u> <ul style="list-style-type: none"> • It was noted that porewater collection is included as a ME for the NBSA but was not done in the Passaic. • Porewater collection and analysis will be added to Table 4-3 (it is currently described in the text, but is missing from the table). • Invertebrates will also be assessed by a comparison of surface water data to surface water screening benchmarks. • In general, comments on the PFD that request restructuring or rewording of measurement endpoints do not need to be addressed because the PFD already contains appropriate text. • Species for toxicity tests were discussed: <ul style="list-style-type: none"> ○ Keep <i>Ampelisca</i> and <i>Leptocheirus</i> as discussed in PFD (sample numbers and specific details will be included in the work plan). Species of test organisms are to be identified definitively in Table 4-3 (the "e.g.," is to be removed from the table). ○ Will likely need to have a 10-day endpoint for <i>Leptocheirus</i>. Data reporting at the 10-day point, if requested, would be part of a 28-day test. ○ It was noted that the eastern oyster was used in the Passaic, but the results were not very useful due to the lack of salinity in the system. ○ Suggested that since oysters are not expected to be widespread or numerous enough to sample in the bay, but other bivalves are (e.g., softshell clams, <i>Macoma sp.</i>) it makes sense to sample those. • Suggest collecting bivalves such as <i>Macoma</i> or softshell clam from the NBSA for tissue analysis. <ul style="list-style-type: none"> ○ If can't achieve enough mass for analysis, then propose caged bivalve studies; analytical hierarchy is the backup if still insufficient mass. • Agreed that a section will be added to the PFD that discusses the history of eastern oysters in the bay, consideration of them as a test species, and ultimate rationale for excluding them (e.g., habitat not widespread, will obtain enough toxicity information from the proposed amphipod studies, other species are more dominant and widespread in the bay). 				

QAPP Worksheet #9 (UFP-QAPP Manual Section 2.5.1): Project Scoping Session Participants Sheet, July 22, 2013

Project Name: Sediment Quality Triad Sampling Projected Date(s) of Sampling: Fall 2013 Project Managers: Carlie Thompson (Tierra)/Melissa Beauchemin (ARCADIS)			Site Name: NBSA Site Location: Newark Bay, New Jersey	
Date of Session: July 22, 2013 Scoping Session Purpose: Discuss sampling and analytical methods.				
Name	Affiliation	Phone #	Email Address	Project Role
Melissa Beauchemin	ARCADIS	978-322-4551	melissa.beauchemin@arcadis-us.com	Project Manager

Cliff Firstenberg	Tierra	757-258-7720	clifford.firstenberg@tierra-inc.com	Project Director
Diane Waldschmidt	EDS	412-486-6989	dwaldschmidt@eds-us.net	QA Coordinator
Mark Harris	ToxStrategies	281-394-1567	mharris@toxstrategies.com	Human Health Risk Assessor
Comments/Decisions: <ul style="list-style-type: none"> Laboratories: decision to use Tierra laboratories (likely two or three laboratories). Analyte list: decision to keep in everything (include herbicides, Aroclors, and butyltins). VOCs do not accumulate in tissue, can eliminate from tissue. VOCs in sediment are limited (most screened out – see Problem Formulation Table 4-2) but will keep in for BHHRA. Discuss process for co-located sediment/clam samples – composites based on areas where clams dug. Tissue processing to be done in laboratory with oversight by ARCADIS biologist. Discussed numbers of organisms to make composite to get enough tissue for all analyses (base on memorandum written for Passaic). 				

QAPP Worksheet #9 (UFP-QAPP Manual Section 2.5.1): Project Scoping Session Participants Sheet, July 29, 2013

Project Name: Sediment Quality Triad Sampling			Site Name: NBSA	
Projected Date(s) of Sampling: Fall 2013			Site Location: Newark Bay, New Jersey	
Project Managers: Carlie Thompson (Tierra)/Melissa Beauchemin (ARCADIS)				
Date of Session: July 29, 2013				
Scoping Session Purpose: Discuss sampling and analytical methods				
Name	Affiliation	Phone #	Email Address	Project Role

Elise Francken	EDS	412-486-6989	efrancken@eds-us.net	Data Validator/QA Assistant
Comments/Decisions:				
<ul style="list-style-type: none"> • Estimated sample size for tissue for each analysis – total is approximately 200 grams. • Need to prioritize analyte list (develop hierarchy). <ul style="list-style-type: none"> ○ Remove VOCs and TPH from tissue. ○ Remove herbicides from tissue (lack of methods). ○ Remove hexavalent chromium from tissue. • The need for Aroclors was discussed. ARCADIS recommends keeping them in the analyte list for trends analysis, but as in the lower Passaic they will not be used in the risk assessment (PCB congener data are better for use in risk assessment). They were maintained in lower Passaic River; however, few data have been collected in NBSA for trend analysis.

Comments/Decisions: <ul style="list-style-type: none"> • Tierra agreed to program for estimating porewater concentrations of contaminants using <i>ex situ</i> passive sampling in the laboratory. • Tierra established DUOs for passive sampling program and USEPA approved the DUOs. • Tierra agreed to talk to experts and research the appropriate methodology and laboratory to conduct passive sampling. 				

QAPP Worksheet #10 (UFP-QAPP Manual Section 2.5.2): Problem Definition

The problem to be addressed by the project:

An understanding of sediment quality in the NBSA through an SQT assessment (surface sediment chemistry analyses, laboratory toxicity testing, and benthic invertebrate community analyses), bioaccumulation tests using invertebrates from which tissue will be collected for chemical analyses, porewater chemical analyses, and surface sediment chemistry analyses to support the BHHRA.

The environmental questions being asked:

- 1) Does exposure to site-related COPCs in the Newark Bay Study Area (NBSA) pose unacceptable risks to benthic invertebrates or other ecological receptors?
- 2) Does the consumption of food web organisms from the lowest trophic levels (i.e., benthic invertebrates) from the NBSA pose unacceptable risks to fish and wildlife receptors (i.e., birds and mammals)?
- 3) Does exposure to COPCs in surface sediments in the intertidal areas of the NBSA pose unacceptable risks to humans via direct contact (e.g., incidental ingestion and dermal contact)?

Observations from any site reconnaissance reports:

A Reconnaissance Survey conducted in September 2013, the results of which are detailed in an April 2015 report entitled *Newark Bay Study Area Reconnaissance Survey Report*, guided the preparation of this Quality Assurance Project Plan (QAPP).

A synopsis of secondary data or information from site reports:

Eight tissue, sediment, and/or surface water investigations have been conducted in the NBSA. Each investigation is summarized below.

- CPG Chemical Water Column Monitoring. Surface water chemistry and surface water quality data were collected from 6 locations in the NBSA between 2011 and 2013. More than 250 samples were collected by the CPG from seven seasonal events at various flow conditions. Results demonstrated that water chemistry in the NBSA is well characterized and there is no need for additional surface water data for risk assessment.
- Contaminant Assessment and Reduction Program (CARP). Fish and blue crab tissue data and sediment data were collected by NJDEP and NYSDEC between 2000 and 2004. Tissue chemistry data were used to select the species appropriate for tissue-residue analysis in the NBSA Phase II program. Tissue data will be incorporated into the tissue dataset to evaluate risks in the baseline risk assessments. The use of these data is limited since only two sampling stations from this study were located in the NBSA.
- NJDEP 2004 Routine Monitoring Program for Toxics in Fish: Year 2 – Estuarine and Marine Waters. NJDEP Crab monitoring program collected crab tissue. All blue crab composite samples were analyzed for both muscle meat and hepatopancreas tissues. Each tissue (i.e., muscle, hepatopancreas) were analyzed for dioxins/furans, PCBs (congener and co-planar), organo-chlorinated pesticides, mercury, and lipids. Tissue data will be incorporated into the tissue dataset to evaluate risks in the baseline risk assessments. The use of these data is limited since only three sampling stations from this study were located in the NBSA.
- Sediment Quality of the NY/NJ Harbor System: a 5-year revisit (1993/4 – 1998). An Investigation under the Regional Environmental Monitoring and Assessment Program (REMAP). USEPA REMAP data include benthic invertebrate numbers and species, as well as sediment chemistry data. The study provides information on dominant clam/bivalve species in the NBSA. Data will be used as historical data to evaluate potential trends or changes in the benthic community assemblage. The use of these data is limited since benthic community assemblages and sediment chemistry in the NBSA may have changed since these data were collected.
- NBSA Phase I and II Sediment Investigations. Tissue collected over 100 sediment cores at various intervals within the NBSA in 2005 and 2007. Surficial sediment data (0 to 0.5 foot) were screened to determine what chemicals to analyze for in surface sediment for the baseline risk assessments. This dataset will be incorporated into the surface sediment data to evaluate potential risks in the baseline risk assessments.

QAPP Worksheet #10 (UFP-QAPP Manual Section 2.5.2): Problem Definition (continued)

- Regional Environmental Monitoring and Assessment Program (2003). Surface sediment samples were collected by USEPA from Upper NY Harbor, Newark Bay, Lower Harbor (includes Raritan and Sandy Hook Bays), and Jamaica Bay from July 1, 2003 through September 25, 2003. Samples were collected from 29 locations in Newark Bay. USEPA REMAP data include benthic invertebrate numbers and species, as well as sediment chemistry data and toxicity test data. This dataset will be incorporated into the surface sediment data to evaluate potential risks in the baseline risk assessments.
- Estimation of the Biologically Active Zone (BAZ) in the NBSA. Tierra conducted a SPI study and limited benthic community characterization to estimate the depth of the BAZ for the NBSA. SPI and surface sediment grab sampling were conducted at 14 locations (five intertidal, six subtidal, and three dredged channel). Grab samples were examined for benthic invertebrates, and sediment textures, colors, and other physical features.
- NBSA Phase III Risk Assessment Activities. Tierra collected (and is continuing to collect) crab, clam, and fish tissue and surficial sediment data (0 to 0.5 foot) to evaluate bioaccumulation of COPECs in the NBSA. Tierra collected blue crab tissue samples and softshell clam tissue samples with co-located surface sediment samples at locations throughout the NBSA in 2014. These samples have not yet been analyzed. Fish tissue samples were also collected in the fall of 2014 and early spring, late spring and summer of 2015. These samples have not yet been analyzed.

The classes of contaminants and the affected matrices:

There are several different classes of organic and inorganic contaminants in the NBSA, many of which accumulate in surface sediment and can be transferred through the food web to upper-trophic level wildlife. Surface sediment samples from approximately the top 6 inches (~15 centimeters) will be analyzed for the following analytes: PCDDs/PCDFs, PCBs (209 individual congeners and Aroclors), metals (including mercury, methylmercury, hexavalent chromium, and titanium), SVOCs (including phthalates), SVOC SIM (including alkylated), VOCs, percent moisture, pesticides, herbicides, butyltins, and total petroleum hydrocarbons. Additional parameters in sediment include total organic carbon, pH, oxidation reduction potential, total sulfide, total phosphorus, total Kjeldahl nitrogen, acid-volatile sulfide/simultaneously extracted metals, ammonia, cyanide, and grain size.

Co-located porewater samples will be analyzed for PCDDs/PCDFs, congener PCBs, metals (including mercury and methylmercury), SVOC SIM (including alkylated), pesticides, dissolved organic carbon, ammonia, and total sulfide.

In addition to the analysis of surface sediment and porewater samples, a 28-day bioaccumulation study will be conducted for the NBSA using a polychaete worm. The bioaccumulation study will provide data on the direct uptake of various chemical contaminants by a key representative invertebrate organism that lives in the sediments of the NBSA. These data will be used to help assess risks to invertebrates, and the movement of contaminants in sediments into the base of the food web for trophic transfer to higher organisms. At the conclusion of the bioaccumulation test, tissue samples from the polychaete worm will be analyzed for the following chemical groups: PCDDs/PCDFs, PCBs (209 individual congeners and Aroclors), metals (including mercury, methylmercury, and titanium), SVOCs (including phthalates), SVOC SIM (including alkylated), percent moisture, pesticides, butyltins, and percent lipids. Although VOCs, hexavalent chromium, and herbicides are identified as possible COPECs/COPCs, VOCs and hexavalent chromium were not identified as bioaccumulative chemicals by USEPA (2000). Therefore, VOCs and hexavalent chromium will not be analyzed in tissue samples. Herbicides are not included for analysis in tissue because: 1) there are no published methods for herbicides in tissue, 2) herbicides are infrequently detected in recent studies, and 3) the bioaccumulation potential is low.

The analysis of PCB Aroclors is being conducted to provide data comparable to historical PCB Aroclor data for the purposes of trend analysis on the basis of PCB Aroclors. The PCB Aroclor data will not be used in either the baseline human health risk assessment (BHHA) or baseline ecological risk assessment (BERA) due to the superior accuracy and precision of the PCB congener data. Total PCB concentrations will be calculated as the sum of PCB congeners and not the sum of PCB Aroclors.

QAPP Worksheet #10 (UFP-QAPP Manual Section 2.5.2): Problem Definition (continued)

The rationale for inclusion of chemical and non-chemical analyses:

SQT assessment results, bioaccumulation test results, porewater chemistry results, and surface sediment chemistry results collected in support of the BHHRA will provide valuable information that will be used to perform the BERA and BHHRA for the NBSA.

Project decision conditions:

Tierra will communicate with USEPA to discuss any pending issues that could impact the project or data quality. Field decisions will be coordinated with USEPA's oversight personnel or USEPA, as required. Such decisions may include modifications to sample locations, weather-related operational decisions, etc.

A key point that may require communication among ARCADIS, the analytical laboratories, Tierra, and USEPA, is the necessity to invoke a hierarchy of chemical analyses for the bioaccumulation task. While sediment is not mass-limited, and the porewater testing circumvents the mass requirement due to the fundamental design of the passive sampling approach, the mass of tissue required for the bioaccumulation tests may not support the full suite of chemical analyses planned for the project. In that case, the hierarchy of analyses, shown below, will be followed.

A minimum sample mass of 194 grams (g) is needed per sample for analysis of all proposed chemical groups. The minimum mass requirements per analytical group are provided in the table below. A mass of 25 g was added to the sum of the minimum mass requirements for chemical analyses (169 g) to account for tissue lost during processing and homogenization, for a total pre-homogenization minimum mass of 194 g. Mass requirements have been optimized with each analytical laboratory, such that they are the lowest required to achieve the detection limits presented in Worksheet No. 15. The minimum volume does not include enough volume for re-extractions or matrix-specific quality control samples. If the minimum tissue mass (169 g) for chemistry analysis cannot be obtained for a given location, the following priority list for the chemical analyses of tissue samples will be applied:

Priority Order	Analytical Group	Required Sample Mass (grams)	Cumulative Mass (grams)
1	PCDDs/PCDFs	30	30
1	Percent Lipids		
2	PCB Congeners	20	50
3	Methylmercury	1	51
4	Mercury	1	52
5	Metals, Titanium	1	53
6	Pesticides	20	73
7	Percent Moisture	1	74
8	SVOCs	15	89
9	SVOC SIM	15	104
10	Butyltins	50	154
11	Aroclor PCBs	15	169

**QAPP Worksheet #11 (UFP-QAPP Manual Section 2.6.1): Project Quality Objectives/Systematic Planning
Process Statements**

Who will use the data?

The data collected under this SQT QAPP will be used by Tierra and USEPA for CERCLA-related decisions, specifically for the BERA and the BHHRA, and by other interested parties (e.g., U.S. Army Corps of Engineers, NJDEP, U.S. Fish & Wildlife Service, N.J. Department of Transportation, National Oceanic and Atmospheric Administration) for other purposes, such as restoration planning.

What will the data be used for?

The data collected during this sampling effort will be used in risk-based decision-making for the remedial investigation/feasibility study (RI/FS) in the Newark Bay Study Area (NBSA). Specifically, the data will be used to estimate potential human health and ecological risks to receptors that may be exposed to COPCs in the NBSA. The results of the baseline risk assessments will be used to inform remedial decision-making under CERCLA/National Contingency Plan and other appropriate regulations and future restoration planning.

BERA Assessment Endpoints:

Assessment Endpoint No. 1 – Survival and/or growth of aquatic plants and maintenance of plants as a food resource and habitat for fish and wildlife

Sediment chemistry data collected as part of this sampling event will be used as a measurement endpoint to evaluate risks to aquatic plants by answering the following risk question: **Are COPEC concentrations in surface water and sediments from the NBSA greater than benchmarks for the survival and/or growth of aquatic plants?** To do this, measured chemical concentrations in sediment will be compared to toxicological benchmarks.

Assessment Endpoint No. 2 – Survival, growth, and/or reproduction of invertebrates

Invertebrates form the base of the food web for fish and other upper-trophic level organisms. The SQT will be the basis for the risk assessment for benthic invertebrates. The SQT incorporates data for sediment (and, in this program, porewater) chemistry, toxicity, and benthic community metrics. Supplemental data from laboratory bioaccumulation testing will also be used to help evaluate risks to benthic invertebrates from the COPECs. The following are specific risk questions that will be addressed from the data collected under this SQTQAPP.

Risk Question: Are invertebrate communities in the NBSA different from those found in water bodies with chemical concentrations consistent with regional reference conditions?

This question will be addressed by comparing community structure data (e.g., total invertebrate abundance, species richness, and abundance of species or specific taxonomic groups) from the NBSA to appropriate regional reference populations using diversity indices, multivariate, and spatial statistical techniques.

Risk Question: Are the COPEC concentrations in sediments from the BAZ greater than benchmarks for the survival, growth, and/or reproduction of invertebrates?

This question will be addressed by comparing chemical concentrations in sediment to toxicological sediment benchmarks from the literature.

Risk Question: Is the survival, growth, and/or reproduction of invertebrates exposed to surface sediments of the NBSA significantly lower than that in reference sediments?

This question will be addressed by evaluating laboratory toxicity test results (survival, growth and reproduction endpoints) developed using NBSA surface sediments with respect to sediment and porewater chemistry and

**QAPP Worksheet #11 (UFP-QAPP Manual Section 2.6.1): Project Quality Objectives/Systematic Planning
Process Statements (continued)**

benthic community data, and in comparison to regional reference datasets. The results will also be evaluated using existing regional reference comparisons to support risk management decisions.

Risk Question: Are COPEC concentrations in surface water from the NBSA greater than toxicological benchmarks for the survival, growth, and/or reproduction of invertebrates?

This question will be addressed by comparing previously-collected dissolved chemical concentrations in surface water to toxicological benchmarks from the scientific literature.

Risk Question: Are COPEC residues in invertebrate tissues from the NBSA greater than tissue benchmarks (e.g., critical body residues [CBRs]) for the survival, growth, and/or reproduction of invertebrates?

This question will be addressed by comparing chemical concentrations in laboratory-exposed invertebrates (i.e., polychaete bioaccumulation test) and site-collected invertebrate tissues (clams/crabs) to literature-based toxicity reference values.

Assessment Endpoints No. 3 and 4 – Survival, growth, and/or reproduction of reptiles and fish, respectively

Sediment chemistry data collected as part of this sampling event will be used as a measurement endpoint to evaluate risks to reptiles and fish by answering the following risk question: **Are COPEC concentrations in site sediment at levels that might adversely affect survival, growth, and/or reproduction of reptiles and fish?** To do this, measured chemical concentrations in sediment will be compared to toxicological benchmarks. In addition, invertebrate tissue and sediment chemistry data collected as part of this sampling event will be used as input parameters for a food web model to estimate dietary intakes for fish.

Assessment Endpoints No. 5 and 6 – Survival, growth, and/or reproduction of birds and mammals

Tissue and sediment chemistry data collected as part of this sampling event will be used as input parameters for a food web model to estimate dietary intakes for select bird and mammal receptors by answering the following risk question: **Does the daily dose of COPECs received by birds and mammals from consumption of the tissues of prey species and from other media in the NBSA exceed the toxicity reference values (TRVs) for survival, growth, and/or reproduction of birds and mammals? If yes, what are the probabilities of effects of differing magnitude for survival, growth, and/or reproduction of birds and mammals?** To do this, measured chemical concentrations in sediment and benthic invertebrate tissue will be incorporated into the food web model to estimate a daily dietary ingestion of chemicals. This value is then compared to the literature-based TRVs to evaluate potential risks. If potential risks are evident (i.e., the resulting hazard quotient is greater than 1), a probabilistic food web model will be run to estimate the range of possible risks following work plan approval by USEPA.

BHHRA Endpoints

The data collected during this sampling effort will also be used to support the BHHRA. In addition to the BERA risk questions outlined above, the BHHRA risk question relevant to this project is:

- What are the potential adverse effects of chemicals in the NBSA to human health under current and future exposure scenarios for both cancer and non-cancer health effects from direct contact (e.g., incidental ingestion and dermal contact) with contaminated sediments in the NBSA?

Human health risks will be evaluated for young children, adolescents, and adults.

**QAPP Worksheet #11 (UFP-QAPP Manual Section 2.6.1): Project Quality Objectives/Systematic Planning
Process Statements (continued)**

For sediment, chemistry data will be collected. The BHHRA will use data from sediment samples as the basis for quantitatively evaluating the reasonable maximum exposure of individuals under current and future exposure scenarios for both cancer and non-cancer health effects, following USEPA Superfund guidance, guidelines, and policies.

Direct contact risks to humans will also be evaluated from exposure to surficial sediment (approximately 0 to 6 inches [~15 centimeters]) in the NBSA.

The rationale for the sample size of surficial sediments collected to support the BHHRA is based on two concepts. First, all areas along Newark Bay that are accessible to humans were identified and at least one sample will be collected at each of these locations. Table 2 of the SQT QAPP provides a description of each sampling location and the rationale for its selection. Second, a review of the sample density of surface sediment samples collected along the accessible portion of the Passaic River (wader exposure scenario) were totaled and divided by the accessible shoreline mileage resulting in approximately 3.8 samples per mile. For the NBSA shoreline, 39 sediment sampling locations have been proposed by the Crab/Clam QAPP or SQT QAPP for the 9.42 miles of shoreline which are designated to have human access points, providing approximately 4.14 samples per mile of accessible shoreline. Thus, the NBSA and Passaic River sampling programs for surface sediment along the shoreline are approximately the same sampling density.

What type of data are needed (matrix, target analytes, analytical groups, field screening, on-site analytical or off-site laboratory techniques, sampling techniques)?

Surface sediment samples from approximately the top 6 inches (~15 centimeters) collected under this QAPP will be used in the BHHRA for the following purposes:

1. Analyses to support the SQT
 - Surface sediment chemistry analyses
 - Benthic invertebrate community analyses
 - Laboratory toxicity testing (from which survival and growth metrics of benthic invertebrates will be developed)
2. Additional lines of evidence to support the baseline ecological risk assessment (BERA)
 - Laboratory bioaccumulation tests using invertebrates from which tissue will be collected for chemical analyses
 - Porewater chemical analyses and estimates using passive sampling methods
3. Surface sediment chemistry analyses to support the baseline human health risk assessment (BHHRA)

Sampling Techniques

Surficial sediment will be collected from each sampling station using a grab sampling device appropriate for the water depth and substrate type. A series of grab samples will be collected at each station to obtain sufficient sediment mass to perform all chemical and toxicological analyses. An initial single sediment grab sample will be collected from the center area of each sampling station for analysis of volatiles, AVS/SEM, and TEPH-purgeables, as described in SOP No. 6 (Appendix B). This sample will not be composited/homogenized with the rest of the collected sediment.

Bulk sediment samples will be collected from each location for the remaining sediment chemistry analyses, sediment toxicity testing, bioaccumulation testing, and ex situ porewater passive sampling. Prior to sample preparation, the bulk sediment samples from each sampling station will be homogenized in a large decontaminated stainless steel bucket with a decontaminated mechanical mixer until textural, color, and moisture homogeneity is achieved. The mechanical mixer will be decontaminated between sampling stations as described in SOP No. 3 – Decontamination (Appendix B). Once homogenized, the appropriate amount of sediment for each analysis will be placed in appropriately labeled sample containers. Sample containers for toxicity and bioaccumulation testing will be lined with a plastic bag prior to filling with sediment. Once filled, all of the air will be

**QAPP Worksheet #11 (UFP-QAPP Manual Section 2.6.1): Project Quality Objectives/Systematic Planning
 Process Statements (continued)**

squeezed out (to minimize ORP and DO changes), and then the bucket will be sealed in preparation for shipment. For ex situ porewater passive sampling, a 4-gallon bulk sediment sample will be collected from each sampling location, homogenized (as described above), and placed in a 5-gallon bucket. The remaining space in each bucket will be filled with site water. Additionally, a 1-L bottle will be filled with the 0.8L aliquot of homogenized sediment in the field during sample processing and prior to shipment to UMBC. This sample will not be taken from the 5-gallon bucket at UMBC. This will minimize further disturbance of the sediments in the 5-gallon buckets where attempts to recreate redox conditions are being conducted. Finally, a minimum of two 5-gallon buckets of site water also will be sent to UMBC for use in the 1-L bottle test chambers, as well as for topping off any test chambers in the event water is lost by evaporation during the experiment. Samples for chemistry analysis will be stored on wet ice for shipment to the designated testing laboratories. Samples for toxicity testing, bioaccumulation testing, and ex situ porewater passive sampling will be refrigerated until shipment to the designated testing laboratories.

Finally, three discrete grab samples will be collected from each station for benthic invertebrate community analysis. Each grab sample will be sieved immediately and independently after collection, as described in SOP No. 6 (Appendix B). The contents of each sieved grab sample will be placed in appropriately labeled sample containers, preserved with isopropyl alcohol, sealed, and shipped to the laboratory conducting the benthic community evaluation. These samples will not be homogenized.

Target Analytes/Analytical Groups

The table below provides a summary of the chemical analyses planned for each sampling matrix.

Analyte Group	Sediment	Porewater	Tissue
PCDDs/PCDFs	X	X	X
Congener PCBs	X	X	X
Aroclor PCBs	X		X
Metals (including titanium)	X	X	X
Mercury	X	X	X
Methylmercury	X	X	X
Hexavalent Chromium	X		
SVOCs (including phthalates)	X		X
SVOC SIM (including alkylated)	X	X	X
VOCs	X		
Percent Moisture	X		X
Pesticides	X	X	X
Herbicides	X		
Butyltins	X		X
Total Petroleum Hydrocarbons	X		
Total Organic Carbon	X		
Dissolved Organic Carbon		X	
pH	X

Total Phosphorus	X		
Total Kjeldahl Nitrogen	X		
AVS/SEM	X		
Ammonia	X	X	
Cyanide	X		
Grain Size	X		
Percent Lipids			X

How “good” do the data need to be in order to support the environmental decision?

The data will be used to support decisions about the magnitude and spatial distribution of risks to human and ecological health. The data will be used to better define risk decisions for discrete endpoints. The data may also be used to support initial investigations of potential remedial options. Consequently, the data need to be collected with a design that specifically addresses the questions that are being posed (see above, “What will the data be used for?”). The conceptual framework of the design is more important than the actual number of samples collected because it is this framework that will be used to extrapolate from the data that are collected in order to draw conclusions about risks at the site.

It is inevitable that some tissue-sediment relationships will be highly variable, while others will not. However, if the data have been collected with a logical design to cover the range of variation in the controlling physical factors at the site, the interpretation of the results is more straightforward, even when the variance of relationships is high. Because a number of assumptions will be made when assessing risks, the data must be collected in a way that makes the evaluation of assumptions possible and allows assessments of the remaining uncertainty to be conducted in a way that enables decision makers to weigh the costs and benefits of proceeding with remedial action decisions.

How much data are needed (number of samples for each analytical group, matrix, and concentration)?

The overall number of sediment samples (and co-located porewater samples) was determined based on statistical evaluation and in coordination with USEPA. In addition, 23 surface sediment sampling stations were selected from locations near where human-sediment contact could potentially occur. Ten of the 23 sampling stations selected to support the BHHRA overlapped with a sampling location already identified for SQT and BERA purposes; therefore, 13 surface sediment stations have been added. These 13 additional sampling locations will only be analyzed for sediment chemistry.

**QAPP Worksheet #11 (UFP-QAPP Manual Section 2.6.1): Project Quality Objectives/Systematic Planning
 Process Statements (continued)**

The table below provides a summary of the SQT, BERA, and BHHRA analyses and numbers of stations/samples to be collected.

Proposed Analysis	Number of Subtidal Flat Stations*	Number of Transitional Slope Stations	Number of Intertidal Stations	Total Number of Sampling Stations
SQT Analyses				
Sediment Chemistry (BHHRA)	14	4	12**	30
Toxicity Testing with <i>L. plumulosus</i> (10-day)	14	4	12	30
Toxicity Testing with <i>L. plumulosus</i> (28-day)	14	4	12	30

Additional Lines of Evidence to Support the BERA				
Bioaccumulation Study (<i>N. virens</i>)	2	1	5	8
Porewater Chemistry	14	4	12	30
Additional sediment chemistry for BHHRA	--	--	13	13

Notes:

*Includes formerly dredged areas in Newark Bay North.

** 10 of the twelve intertidal stations are being used to support the BHHRA

Where, when, and how should the data be collected/generated?

Sediment samples will be collected from the Subtidal Flats, Intertidal Areas, and Transitional Slopes of the NBSA (Figure 1). Samples will be collected by locating the sampling stations using maps and GPS coordinates. Upon reaching each sampling station, the GPS coordinates will be recorded on the field datasheet. All samples will be collected from approximately the top 6 inches (~15 centimeters) of sediment.

Sampling is expected to occur in September 2015. The date and time of sample collection at each station will be recorded.

Sediment will be collected from each sampling station using a grab sampling device appropriate for the water depth and substrate type; a series of grab samples will be necessary at each station to obtain sufficient sediment mass to perform all chemical and toxicological analyses.

Sediment chemistry data will be collected from 23 locations in the NBSA to support both the BERA and the BHHRA.

Toxicity data will be collected in the laboratory at the culmination of the test period. Two toxicity tests will be conducted using *Leptocheirus plumulosus*: one is a short-term 10 day exposure study and the second is a longer-term 28-day exposure study. Survival, reproduction, and growth rates will be recorded for individual organisms at the end of each test period. The toxicity tests must meet the performance standards for these tests provided by the American Society for Testing and Materials (ASTM) and USEPA presented in Table 11-1.

**QAPP Worksheet #11 (UFP-QAPP Manual Section 2.6.1): Project Quality Objectives/Systematic Planning
Process Statements (continued)**

A 28-day bioaccumulation study will be conducted in the laboratory for the NBSA using the polychaete worm (*N. virens*). At the end of the 28-day study, viable organisms will be sent to the analytical laboratory(ies) for chemical analysis of tissue. The bioaccumulation tests must meet the performance standards for these tests provided by the ASTM and USEPA presented in Table 11-2.

Benthic communities will be analyzed by identifying and enumerating the benthic invertebrates from sediment grab samples collected at the 30 SQT locations. The benthic community samples will be identified to the lowest practicable taxonomic level and, in accordance with other surveys in the NY/NJ Harbor Estuary (Weisberg et al. 1997), various benthic metrics, including, but not limited to, species richness, abundance, and diversity, will be calculated at each SQT station. Total abundance, abundance per taxonomic group and benthic community structure will be compared to appropriate background datasets using diversity indices, multivariate, and spatial statistical techniques. Taxonomic level will be identified to the Lowest Practical Identification Level (LPIL) standard.

Porewater samples will be collected in the laboratory using passive samplers; a series of porewater samples will be necessary to obtain sufficient volume to perform all chemical analyses.

The surface sediment chemistry, porewater chemistry, toxicity, benthic community and bioaccumulation data collected under this SQT program will be subjected to pairwise and multivariate statistical analyses. The goal of these analyses is to determine if exposure-response relationships exist in the NBSA between given chemical and/or physical measures in sediment and porewater and toxicological, bioaccumulation and/or benthic community results/metrics.

Who will collect and generate the data?

As described in Worksheet No. 7, ARCADIS will provide the field sampling coordination and personnel required to conduct the sediment collection efforts. FTS will provide laboratory coordination and support.

How will the data be reported?

Daily activities will be communicated (e.g., telephone conversation, email) to Project Managers and the Facility Coordinator, as described in Worksheet No. 6.

An electronic database that includes the coordinates for the collection of each sediment sample will be provided. The database will include GPS coordinates of each station, time of sample collection, and depth of sample collection.

A data report(s) summarizing the sediment collection and SQT assessment (sediment chemistry, toxicity testing, and benthic invertebrate community analysis), bioaccumulation test, porewater, and BHHRA-specific sediment chemistry analysis results will be provided 90 days after receipt of all Phase III validated chemical data. In addition, this report will include maps that present the sampling locations.

How will the data be archived?

Data records, forms, and notes will be scanned and stored electronically in a project file. Hard copies will be archived in Tierra's main office in East Brunswick, New Jersey. Similarly, the data reports will be issued and then archived electronically and as hard copies. The analytical results will also be provided, as electronic data deliverables, to the project database. Multimedia electronic data deliverables will be provided to USEPA Region 2 by FTS in their required format.

**QAPP Worksheet #11 (UFP-QAPP Manual Section 2.6.1): Project Quality Objectives/Systematic Planning
 Process Statements (continued)**

Table 11-1. Quality Indicators for Toxicity Testing Based on ASTM and USEPA Protocols

Test	Quality Indicators
10-day <i>Leptocheirus plumulosus</i> test	<ul style="list-style-type: none"> • Minimum control survival of 90%. • All organisms in a test must be from the same source. • Test organisms must be cultured at 20°C (± 1°C) and tested at 25°C (± 1°C). • Immature test organisms must be 2-4 mm in length. • All test chambers should be identical and should contain the same amount of sediment and overlying water. • Daily pH measurements within the test chambers must be between 6.0 and 9.0 standard units. • Daily dissolved oxygen measurements within the test chambers must be greater than 2.5 mg/L. • Daily salinity measurements within the test chambers must be within 2 ppt of 20 ppt. • Natural physico-chemical characteristics of test sediment collected from the field should be within the tolerance limits of the test organisms. • Storage of sediment collected in the field should be ≤ 8 weeks. • Storage of sediments for toxicity testing should be at 4°C.
28-day <i>Leptocheirus plumulosus</i> test	<ul style="list-style-type: none"> • Minimum control survival of 80%. • All organisms in a test must be from the same source. • Test organisms must be cultured and tested at 20°C (± 1°C). • Immature test organisms must be 2-4 mm in length. • All test chambers should be identical and should contain the same amount of sediment and overlying water. • Daily pH measurements within the test chambers must be between 6.0 and 9.0 standard units. • Daily dissolved oxygen measurements within the test chambers must be greater than 2.5 mg/L. • Daily salinity measurements within the test chambers must be within 2 ppt of 20 ppt. • Natural physico-chemical characteristics of test sediment collected from the field should be within the tolerance limits of the test organisms. • Storage of sediment collected in the field should be ≤ 8 weeks. • Storage of sediments for toxicity testing should be at 4°C.

**QAPP Worksheet #11 (UFP-QAPP Manual Section 2.6.1): Project Quality Objectives/Systematic Planning
 Process Statements (continued)**

Table 11-2. Quality Indicators for Bioaccumulation Tests Based on ASTM and USEPA Protocols

Test	Quality Indicators
28-day <i>Neanthes virens</i> test	<ul style="list-style-type: none"> • Sufficient biomass for chemical analysis (194 grams). • All organisms in a test must be from the same source. • Test organisms must be cultured and tested at 20°C (± 1°C). • Daily pH measurement within the test chambers must be between 6.0 and 9.0 standard units. • Daily dissolved oxygen measurements within the test chambers must be greater than 2.5 mg/L. • Daily salinity measurements within the test chambers must be within 3 ppt of 30 ppt. • All test chambers should be identical and should contain the same amount of sediment and overlying water. • Natural physico-chemical characteristics of sediment collected from the field should be within tolerance limits of the test organisms. • Storage of sediment collected in the field should be ≤ 8 weeks, preferably ≤14 days. • Storage of sediments for toxicity testing should be at 4°C.

Notes:

- ^a If information varies within an analytical group, separate by individual analyte.
- ^b Reference number from Worksheet #21.
- ^c Reference number from Worksheet #23.
- ^d Trip blanks will be collected, travel with environmental samples, and be submitted for analysis in association with any samples collected for volatile organics, mercury or methylmercury analysis.
- ^e Surrogate spikes and/or LCS recovery criteria values are updated every 6 months by the laboratory.

DCAA = 2,4-dichlorophenylacetic acid

PCBs = polychlorinated biphenyls

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/dibenzofurans

PQL = project quantitation limit

QC = quality control

RPD = relative percent difference

SIM = selective ion monitoring

SOP = Standard Operating Procedure

TAL = Target Analyte List

TEPH = total extractable petroleum hydrocarbons

TOC = total organic carbon

% = percent

QAPP Worksheet #12-1 (UFP-QAPP Manual Section 2.6): Measurement Performance Criteria – Blanks (continued)

Definitions of Terms:

Field Blank = Sample collected by pouring de-ionized water or solvent, whichever is appropriate for the constituents of interest, over the decontaminated sediment sample collection and processing equipment in the field. Field blanks will be prepared for each decontamination event at a frequency not to exceed one per day and will be traceable to the sediment samples collected and processed on that day or associated with that decontamination event, whichever is applicable. Field blanks check for potential contamination prior to sampling, sample processing, and transportation of sediment samples.

Rinse Blank = Sample collected by pouring de-ionized water or solvent, whichever is appropriate for the constituents of interest, over the decontaminated homogenization equipment being used in the analytical laboratory. Rinse blanks will be prepared for each decontamination event at a frequency not to exceed one per day and will be traceable to the tissue samples prepared on that day or associated with that decontamination event, whichever is applicable. Rinse blanks check primarily for potential contamination that may be caused by reuse of decontaminated homogenization equipment, however, contamination from the sampling process and transportation will also be captured.

Trip Blank = Sample matrices that are as free of volatile analytes as possible and transported with the samples to the laboratory without being opened. Trip blanks will be shipped with each shipment of samples that contains any volatile organics, mercury, or methylmercury field samples. Trip blanks check for potential contamination during transport and storage before analysis.

Passive Sampler Blank = The passive sampler blank for organics will be an unused PE and/or POM sampler placed in DI water. The PE and/or POM sampler will be agitated in the DI water for the same amount of time as the PE and/or POM samplers are agitated in the sediment slurry. At the end of the testing period, the PE and/or POM strips will be shipped to the laboratories for chemical analysis. The passive sampler blank for inorganics will be an unused dialysis bag filled with DI water. The DI water will be allowed to sit in the dialysis bag for the same amount of time as the dialysis bags are exposed to the sediment and under the same light and temperature conditions. At the end of the testing period, the dialysis bags filled with DI water will be shipped to the laboratories for chemical analysis.

QAPP Worksheet #12-2 (UFP-QAPP Manual Section 2.6): Measurement Performance Criteria – Sediment

Matrix	Sediment					
Analytical Group ^a	PCDDs/PCDFs					
Concentration Level	Low					
Sampling Procedure ^b	Analytical Method/SOP ^c	Data Quality Indicators (DQIs)	Measurement Performance Criteria	QC Sample and/or Activity Used to Assess Measurement Performance	QC Sample Assesses Error for Sampling (S), Analytical (A) or both (S & A)	
SOP-6	L-1	Precision - Lab	<u>Compound</u> All target analytes	<u>RPD</u> <50	Matrix Spike Duplicate	A
		Accuracy/Bias	<u>Compound</u> All analytes	<u>% Recovery</u> 60-140	Matrix Spike	A
		Accuracy/Bias	All target compound concentrations must fall within the acceptance ranges provided in Table 6 of L-1		Ongoing Precision and Recovery	A
		Accuracy/Bias Contamination	No target compounds ≥PQL		Method Blanks and Field Blanks	S & A
		Accuracy/Bias	All certified target compound concentrations must be within ± 25% of certified value when concentrations fall within the range of the initial calibration.		Performance Evaluation Sample	A
		Completeness	>90% sample collection, >90% laboratory analysis		Data Completeness Checks	S & A
		Precision - Overall	RPD ≤50% when target is detected in both field duplicate samples at >5X PQL, or concentrations differ by <2X the PQL when detects are <5X PQL for both field duplicate samples		Field Duplicate	S & A
		Accuracy/Bias	Per L-1		Initial Calibration	A

		Precision - Overall	RPD \leq 25%	Field Duplicate	S & A

Notes:

- ^a If information varies within an analytical group, separate by individual analyte.
- ^b Reference number from Worksheet #21.
- ^c Reference number from Worksheet #23.
- ^d Trip blanks will be collected, travel with environmental samples, and be submitted for analysis in association with any samples collected for volatile organics, mercury, or methylmercury analysis.
- ^e Surrogate spikes and/or LCS recovery criteria values are updated every 6 months by the laboratory.

AVS/SEM = acid volatile sulfide/simultaneously extracted metals
 DCAA = 2,4-dichlorophenylacetic acid
 mV = millivolts
 PCBs = polychlorinated biphenyls
 PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/dibenzofurans
 PQL = project quantitation limit
 QC = quality control
 RPD = relative percent difference
 SIM = selective ion monitoring
 SOP = Standard Operating Procedure
 TAL = Target Analyte List
 TEPH = total extractable petroleum hydrocarbons
 TOC = total organic carbon
 USEPA = U.S. Environmental Protection Agency
 % = percent

QAPP Worksheet #12-4 (UFP-QAPP Manual Section 2.6): Measurement Performance Criteria – Porewater (continued)

Notes:

- ^a If information varies within an analytical group, separate by individual analyte.
- ^b Reference number from Worksheet #21.
- ^c Reference number from Worksheet #23.
- ^d Trip blanks will be collected, travel with environmental samples, and be submitted for analysis in association with any samples collected for mercury or methylmercury analysis.
- ^e Surrogate spikes and/or LCS recovery criteria values are updated every 6 months by the laboratory.

Definitions of Terms:

DCAA = 2,4-dichlorophenylacetic acid

PCBs = polychlorinated biphenyls

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/dibenzofurans

PQL = project quantitation limit

QC = quality control

RPD = relative percent difference

SIM = selective ion monitoring

SOP = Standard Operating Procedure

TAL = Target Analyte List

TEPH = total extractable petroleum hydrocarbons

% = percent

QAPP Worksheet #12-5 (UFP-QAPP Manual Section 2.6): Measurement Performance Criteria – Benthic Invertebrate Community Analysis, Toxicity Tests, and Bioaccumulation Test

Test	Analytical Method/SOP	Data Quality Indicators (DQIs)	Measurement Performance Criteria
Benthic Invertebrate Community Analysis	L35, L-36	Identification Accuracy Count Accuracy Sorting Efficiency	≥90% of original identifications and taxa counts confirmed by second biologist (re-identify 10% of samples from consecutive batches of 10) ≥90% of original gross counts confirmed by QA/QC count (re-count 10% of samples from consecutive batches of 10) ≥90% sorting efficiency confirmed by QC sample (re-sort one randomly selected sample from each batch of 10 samples for each sample collection date)
Bioaccumulation Test with Polychaete Worm	L-37	Dissolved Oxygen pH Temperature Salinity Survival	>2.5 mg/L 6.0-9.0 SU 20±1°C 30±3 ppt Sufficient biomass for analysis (194 grams)
Toxicity Test, 10-day, with <i>L. plumulosus</i>	L-38	Dissolved Oxygen pH Temperature Salinity Survival	>2.5 mg/L 6.0-9.0 SU 25±1°C 20±2 ppt ≥90% survival in control sediment
Toxicity Test, 28-day, with <i>L. plumulosus</i>	L-39	Dissolved Oxygen pH Temperature Salinity Survival Growth Reproduction	>2.5 mg/L 6.0-9.0 SU 20±1°C 20±2 ppt ≥80% survival in control sediment None None

Definitions of Terms:

% = percent
°C = degrees Celsius
mg/L = milligrams per liter
ppt = parts per thousand
SU = standard units

QAPP Worksheet #13 (UFP-QAPP Manual Section 2.7): Secondary Data Criteria and Limitations Table

Secondary Data	Data Source (Originating Organization, Report Title, and Date)	Data Generator(s)	Data Use	Limitations on Data Use
NBSA Sampling Performed by Others				
Surface Water Data	CPG Chemical Water Column Monitoring, available online at (www.ourpassaic.org)	Surface water data collected by CPG between 2011 and 2013	Surface water chemistry and quality data collected at 6 locations between 2011 and 2013. More than 250 samples collected from seven seasonal events at various flows. Results demonstrated that water chemistry in NBSA is well characterized and there is no need for additional surface water data for risk assessment.	None.
Tissue and Sediment Data	Contaminant Assessment and Reduction Program, available online at (http://www.carpweb.org/main.html)	Fish and blue crab tissue data and sediment data collected by NJDEP and NYSDEC between 2000 and 2004.	Tissue chemistry data were used to select the species appropriate for tissue-residue analysis. Tissue data will be incorporated into the tissue dataset to evaluate risks in the baseline risk assessments.	Only two stations in Newark Bay.
Tissue Data	NJDEP 2004 Routine Monitoring Program for Toxics in Fish: Year 2 – Estuarine and Marine Waters. NJDEP Crab Monitoring Program available online at (http://www.state.nj.us/dep/dsr/2004data.htm is the correct link).	NJDEP Crab Monitoring Program collected crab tissue.	All blue crab composite samples were analyzed for both muscle meat and hepatopancreas tissues. Each tissue (i.e., muscle, hepatopancreas) were analyzed for dioxins/furans, PCBs (congener and co-planar), organo-chlorinated pesticides, mercury, and lipids. Tissue data will be incorporated into the tissue dataset to evaluate risks in the baseline risk assessments.	Only three stations in Newark Bay.
Tissue and Sediment Data	Final Report. Sediment Quality of the NY/NJ Harbor System: a 5-year revisit (1993/4 – 1998) An Investigation under the Regional Environmental Monitoring and Assessment Program (REMAP) (USEPA 2003)	USEPA REMAP data includes benthic invertebrate numbers and species	Provides information on dominant clam/bivalve species in the NBSA. Sediment chemistry also collected. Data will be used as historical data to evaluate potential trends or changes in the benthic community assemblage.	Benthic community assemblages and sediment chemistry may have changed since these data were collected.

QAPP Worksheet #13 (UFP-QAPP Manual Section 2.7): Secondary Data Criteria and Limitations Table

Secondary Data	Data Source (Originating Organization, Report Title, and Date)	Data Generator(s)	Data Use	Limitations on Data Use
Tissue and Sediment Data	Regional Environmental Monitoring and Assessment Program (REMAP) (USEPA 2003)	USEPA REMAP data include benthic invertebrate numbers and species, sediment chemistry, and toxicity testing. Surface sediment samples were collected from Upper NY Harbor, Newark Bay, Lower Harbor (includes Raritan and Sandy Hook Bays), and Jamaica Bay from July 1, 2003 through September 25, 2003. Samples were collected from 29 locations in Newark Bay.	USEPA REMAP data include benthic invertebrate numbers and species, as well as sediment chemistry data and toxicity test data. Data will be used to evaluate potential risks in the baseline risk assessments.	Benthic community assemblages and sediment chemistry may have changed since these data were collected.
Work Performed by Tierra on NBSA				
Sediment Data	Phase I and II Sediment Investigations	Tierra collected over 100 sediment cores at various intervals	Surficial sediment data (0 to 0.5 foot) screened to determine what chemicals to analyze for in surface sediment. Dataset will be incorporated into the surface sediment data to evaluate potential risks in the baseline risk assessments.	None.
Sediment Profile Imaging (SPI) and Benthic Community Characterization	Estimation of the Biologically Active Zone (BAZ), Newark Bay, New Jersey	Tierra implemented a SPI study and limited benthic community characterization to estimate the depth of the BAZ for the NBSA	SPI and surface sediment grab sampling conducted at 14 locations (five intertidal, six subtidal, and three dredged channel). Grab samples examined for benthic invertebrates, and sediment textures, colors, and other physical features. Dataset evaluated to estimate the BAZ.	None within the specific data use objective defined for the study.

QAPP Worksheet #13 (UFP-QAPP Manual Section 2.7): Secondary Data Criteria and Limitations Table

Secondary Data	Data Source (Originating Organization, Report Title, and Date)	Data Generator(s)	Data Use	Limitations on Data Use
Tissue and Sediment Data	Phase III Risk Assessment Investigations	<p>Tierra collected blue crab tissue samples, softshell clam tissue samples, and co-located surface sediment samples at locations throughout the NBSA in 2014. These samples have not yet been analyzed.</p> <p>Fish tissue samples were also collected in the fall of 2014 and early spring, late spring, and summer of 2015. These samples have not yet been analyzed.</p>	Crab, clam, and fish tissue and surficial sediment data (0 to 0.5 foot) collected to evaluate bioaccumulation of COPECs in the NBSA.	Not known at this time; only locational information was used for SQT QAPP planning purposes.

QAPP Worksheet #14 (UFP-QAPP Manual Section 2.8.1): Summary of Project Tasks

The sediment collected under this QAPP will be used in the Baseline Human Health and Ecological Risk Assessment (BHHERA) for the following purposes:

1. Analyses to support the SQT
 - Surface sediment chemistry analyses
 - Benthic invertebrate community analyses
 - Laboratory toxicity testing (from which survival and growth metrics of benthic invertebrates will be developed)
2. Additional lines of evidence to support the baseline ecological risk assessment (BERA)
 - Laboratory bioaccumulation tests using invertebrates from which tissue will be collected for chemical analyses
 - Porewater chemical analyses and estimates using passive sampling methods
3. Surface sediment chemistry analyses to support the baseline human health risk assessment (BHHRA)

Sampling Tasks:

Samples will be collected by locating the sampling stations through maps and global positioning system (GPS) coordinates, as described in Standard Operating Procedure (SOP) No. 2 (Appendix B). Upon reaching each sampling station, the GPS coordinates will be recorded on the field datasheet. In addition, general observations about the sampling station will be documented, including the presence/absence of vegetation, general substrate appearance and texture, and tidal stage. The time of sample collection at each station will also be recorded. Water quality will be measured in the field during sediment collection using multi-parameter water quality meter if surface water is present. Recorded water quality parameters include pH, temperature, conductivity, salinity, and dissolved oxygen.

Sediment will be collected from 43 stations as part of this QAPP. SQT analyses (sediment chemistry, toxicity testing with *L. plumulosus*, and benthic invertebrate community analysis) will be conducted at 30 stations. As additional lines of evidence to support the BERA, porewater chemistry analyses will be conducted at all 30 locations and bioaccumulation tests will be conducted at a subset of eight stations. In support of the BHHRA, 23 surface sediment sampling stations were selected from locations near where human-sediment contact could potentially occur. Ten of the 23 sampling stations selected to support the BHHRA overlapped with a sampling location already identified for SQT and BERA purposes; therefore, only 13 additional surface sediment stations have been added.

At each location, approximately the top 6 inches (~15 centimeters) of sediment will be collected from each sampling station using a grab sampling device appropriate for water depth and substrate type (e.g., hand auger, Ponar dredge); a series of grab samples will be necessary at each station to obtain sufficient sediment mass to perform all chemical and toxicological analyses. An initial single sediment grab sample will be collected from the center area of each sampling station for analysis of some volatiles (e.g., VOCs, acid volatile sulfide), as described in SOP No. 6 (Appendix B). This sample will not be composited/homogenized with the rest of the collected sediment.

Bulk sediment samples will be collected from each location for the remaining sediment chemistry analyses, sediment toxicity testing, bioaccumulation testing, and ex situ porewater passive sampling. Prior to sample preparation, the bulk sediment samples from each sampling station will be homogenized in a large stainless steel bucket with a decontaminated mechanical mixer until textural, color, and moisture homogeneity is achieved. The mechanical mixer will be decontaminated between sampling stations as described in SOP No. 3 – Decontamination (Appendix B). Once homogenized, the appropriate amount of sediment for each analysis will be placed in appropriately labeled sample containers. Sample containers for toxicity and bioaccumulation testing will be lined with a plastic bag prior to filling with sediment. Once filled, all of the air will be squeezed out (to minimize ORP and DO changes), and then the bucket will be sealed in preparation for shipment. For ex situ porewater passive sampling, a 4-gallon bulk sediment sample will be collected from each sampling location, homogenized (as described above), and placed in a 5-gallon bucket. The remaining space in each bucket will be filled with site water. Additionally, a 1-L bottle will be filled with the 0.8L aliquot of homogenized sediment in the field during sample processing and prior to shipment to UMBC. This sample will not be taken from the 5-gallon bucket at UMBC. This will minimize further disturbance of the sediments in the 5-gallon buckets where attempts to recreate redox conditions are being conducted. Finally, a minimum of two 5-gallon buckets of site water also will be sent to UMBC for use in the 1-L bottle test chambers, as well as for topping off any test chambers in the event water is lost by evaporation during the experiment. Samples for chemistry analysis will be stored on wet ice for shipment to the designated testing laboratories. Samples for

QAPP Worksheet #14 (UFP-QAPP Manual Section 2.8.1): Summary of Project Tasks (continued)

toxicity testing, bioaccumulation testing, and ex situ porewater passive sampling will be refrigerated until shipment to the designated testing laboratories.

Finally, three discrete grab samples will be collected from each station for benthic invertebrate community analysis. Each grab sample will be sieved immediately and independently after collection as described in SOP No. 6 (Appendix B). Contents of each sieved grab sample will be placed in the appropriately labeled sample containers, preserved with isopropyl, and sealed as described in SOP No. 5 (Appendix B). These samples will not be homogenized.

The table below provides a summary of the analyses to be performed, the sample collection technique to be used, and the mass required for analysis.

Analysis	Purpose of Analysis	Sample Collection Technique	Mass/Volume Required per Sample
Sediment Chemistry	Support the SQT and BHHRA	Grab sample (homogenized)	785 g
		Discrete grab sample (for volatiles)	15 g
		Discrete grab sample (for AVS/SEM)	60 g
		Discrete grab sample (for TEPH-purgeables)	15 g
Benthic Invertebrate Community Analyses	Support the SQT	Discrete grab samples	Not Applicable
Laboratory Toxicity Testing (<i>L. plumulosus</i>) (10-day)	Support the SQT	Bulk sediment sample (homogenized)	2 L
Laboratory Toxicity Testing (<i>L. plumulosus</i>) (28-day)	Support the SQT and BHHRA	Bulk sediment sample (homogenized)	3 L
Bioaccumulation Tests	Support the BERA	Bulk sediment sample (homogenized)	25 L
		Tissue sample (homogenized)	200 g
Porewater Analyses	Support the BERA	Bulk sediment sample (homogenized)	4 gallons (~15 L) sediment, 1 gallon (~3.8 L) site water

For a detailed description of sediment collection, refer to Standard Operating Procedure Nos. 5 and 6 (Appendix B).

Analysis Tasks:

Sediment Chemistry

Following the sediment collection, samples will be processed in the field and shipped to the analytical laboratory for analysis. Sediment samples will be submitted for laboratory analysis of the chemicals listed in Worksheet No.15-2.

Sediment Toxicity Testing

A 10-day toxicity test for survival using *L. plumulosus* will be conducted on the sediment samples collected from the 30 SQT stations proposed for the NBSA using USEPA (1994) *Methods for Assessing the Toxicity of Sediment-associated Contaminants with Estuarine and Marine Amphipods* (EPA/600/R-94/025) and ASTM International (ASTM 2008) *Standard Guide for Measuring the Toxicity of Sediment-Associated Contaminants with Marine and Estuarine Amphipods* (E-1267-03). A 28-day toxicity study for survival, growth, and reproduction using the amphipod *L. plumulosus* will also be conducted on sediment samples collected from the 30 SQT stations proposed for the NBSA using USEPA (2001) *Methods for Assessing the Chronic Toxicity of Marine and Estuarine Sediment-associated Contaminants with the Amphipod, Leptocheirus plumulosus* (EPA/600/R-01/0250).

QAPP Worksheet #14 (UFP-QAPP Manual Section 2.8.1): Summary of Project Tasks (continued)

Sediment Benthic Community Analysis

Benthic communities will be analyzed by identifying and enumerating the benthic invertebrates from sediment grab samples collected at the 30 SQT locations. The benthic community samples will be identified to the lowest practicable taxonomic level and, in accordance with other surveys in the NY/NJ Harbor Estuary (Weisberg et al. 1997, as cited in USEPA 1998), various benthic metrics, including, but not limited to, species richness, abundance, and diversity, will be calculated at each SQT station. A benthic index of biotic integrity assessment will also be conducted using these data following the approach by the USEPA REMAP (USEPA 1998).

Bioaccumulation

A 28-day bioaccumulation study will be conducted for the NBSA using the polychaete worm, *Nereis virens* following *American Society for Testing and Materials (2010) E-1688 Standard Guide for Determination of the Bioaccumulation of Sediment-associated Contaminants by Benthic Invertebrates*. Laboratory bioaccumulation testing will be conducted on sediments collected from a subset of the SQT stations. Bioaccumulation study locations are depicted on Figure 1. The target chemical groups for tissue analysis resulting from the bioaccumulation study are provided in Worksheet No. 15-3.

Porewater

Porewater will be collected via passive samplers in a laboratory environment. Hydrophobic chemicals (i.e., PCBs, SVOC SIM, PCDD/PCDFs, pesticides) will be sampled using polyethylene (PE) and polyoxymethylene (POM) passive samplers, and dialysis samplers will be used for the sampling of metals and other inorganics. Porewater collected via the passive samplers will be submitted for laboratory analysis of the chemicals listed in Worksheet No.15-4.

Quality Control Tasks:

All field notes and forms completed during the field sampling task will be checked daily by the Field Supervisor. The Field Supervisor will also communicate daily with the Task Quality Assurance / Quality Control (QA/QC) Manager to confirm objectives are being met.

Electronic sampling equipment (e.g., scale, GPS units) will be calibrated, maintained, tested, and inspected according to manufacturers' specifications, as necessary, to confirm they are functioning properly (refer to Worksheet No. 22).

Laboratory procedures will be carried out per the SOPs and analytical methodologies provided in the appendices of this document. In addition, field and laboratory quality control samples will be processed as indicated in Worksheets Nos. 28-1 and 28-2. Project quality objectives and measurement performance criteria will be monitored throughout project implementation and at the conclusion of field and analytical activities. Data produced will undergo data validation steps specified in Worksheets Nos. 34, 35 and 36. These data evaluation steps will be performed by the Quality Assurance Coordinator, an organization independent from those generating the data.

Additionally, Tierra will submit pre-program performance evaluation (PE) samples to the laboratories for analysis, and on an on-going basis throughout the sample collection phase.

QAPP Worksheet #14 (UFP-QAPP Manual Section 2.8.1): Summary of Project Tasks (continued)

Planned PE samples include the following:

Analytical Group	Matrix
Polychlorinated Dibenzo- <i>p</i> -dioxins / Polychlorinated Dibenzofurans	Sediment and Tissue
Polychlorinated Biphenyl Congeners	Sediment and Tissue
Organochlorine Pesticides	Sediment and Tissue
Semivolatile Organics SIM	Sediment and Tissue
Mercury	Sediment and Tissue
Methylmercury	Sediment and Tissue
Target Analyte List Metals	Sediment and Tissue
Percent Lipids	Tissue only

Per agreement between Tierra and USEPA Region 2, ongoing PE samples will be submitted to the appropriate laboratory for analysis at the following frequency: one PE sample (as described in the table above) for each sample delivery group (SDG) that contains samples that are split for analysis by both Tierra's laboratory(ies) and USEPA's laboratory. In the case of the remaining SDGs (those that do not contain samples split between Tierra and USEPA laboratories) one PE sample (as described in the table above) will be submitted to Tierra's laboratory(ies) for every 40 field samples collected.

Secondary Data:

Historical tissue and chemistry data that are summarized in Worksheet Nos. 10 and 13 will also be reviewed and used to accomplish project objectives.

Data Management Tasks:

The data management task will include keeping accurate records of field activities and observations so that project team members using the data will have accurate and appropriate documentation. Field data will be stored in its native format and in the project sampling database. GPS data will also be downloaded and stored electronically in a project file. Laboratory analytical data will be loaded into the project sampling database, verified against the laboratory reports, merged with corresponding field data, and updated based on validation. Subsequently, the spatial data will be mapped for the data report.

Documentation and Records:

It is important that field activities be documented in an organized, chronologically accurate manner. All field activities will be recorded in a field notebook maintained by the Field Supervisor. The field notebook is intended to provide sufficient data and observations to enable participants to reconstruct events that occurred during the sampling period. Procedures for documentation are presented in SOP No. 8. All relevant forms and records are presented on Worksheet No. 29. In general, the following information must be recorded:

- The identities and affiliations of the personnel conducting field activities.
- Model numbers and serial numbers of instruments and/or equipment being used, to the extent available.
- A description of the type of field work being conducted and the equipment used.
- The date and time the field activities were initiated and completed, with specific temporal information for each task (e.g., record the time activities commenced at each individual location, if applicable).
- The site where the field activities were conducted and any locations within that site where work was performed (e.g., specific sampling sites, coordinates, depths).
- The general methodology used to conduct the activities.
- Communications with Project Managers and personnel regarding field activities.
- Field data (e.g., GPS measurements, catch totals).
- Daily health and safety briefings.

QAPP Worksheet #14 (UFP-QAPP Manual Section 2.8.1): Summary of Project Tasks (continued)

- Deviations from this SQT QAPP, SOP, or project Health and Safety Plan, reason for change, and any corrective actions taken. Corrective actions will be electronically documented on the Protocol Modification Form (Appendix A).
- Photos will be captured of the composite samples. When photos associated with sampling locations, field activities, or samples are taken, they will be documented in the field notebook, including the date, time, photographer, and brief description.

All sediment samples that will be analyzed will be recorded electronically in the Surface Sediment Collection Form (Appendix A) by field personnel.

A record of all personnel briefed on the Health and Safety Plan will be maintained by the Field Supervisor, Site Safety and Health Officer, or designee. The record will be archived at Tierra's office upon completion of the sampling efforts.

Analytical laboratories will provide complete hard copy analytical data packages, as outlined in Worksheets Nos. 29-2 and 29-3. Specifications for electronic laboratory data deliverables are located in Worksheet No. 29-4. Non-analytical laboratories will provide complete hard copy data packages per laboratory SOPs.

Assessment/Audit Tasks:

Assessment/audit tasks will be conducted, as summarized below:

1. Field Readiness Review. Refer to Worksheet Nos. 31 and 32.
2. Laboratory Readiness Review. Refer to Worksheet Nos. 31 and 32.
3. Field Sampling Technical Systems Audit. Refer to Worksheet Nos. 31 and 32.
4. Internal Field Audit. Refer to Worksheet Nos. 31 and 32.
5. Data Validation.
6. Data Usability Assessment Report.

Data Review Tasks:

All field records will be reviewed by the Field Supervisor for completeness and accuracy and verified by the Task QA/QC Manager or a designee.

Contract laboratories will verify that all data are complete for samples received. All data package deliverable requirements will be met. Data will be validated by FTS per the requirements specified in Worksheets Nos. 34, 35 and 36. A Data Validation Report will be produced for each sample delivery group and each analytical group.

Validated data and all related field logs/notes/records will be reviewed to assess total measurement error and determine overall usability of the data for project purposes. Data limitations will be determined and data will be compared to project quality objectives and required action limits. Corrective action will be initiated, as necessary. Final data will be placed in the database, with necessary qualifiers.

As part of data report preparation, chemical data will be reviewed to determine if differences related to species and/or location are evident. In addition, the data report will also undergo a senior and peer review process before the final draft is submitted to USEPA (see Worksheet Nos. 34 through 37 for relevant procedures).

A tissue chemistry data report will be prepared once all of the tissue chemistry results (including all Phase III data) have been validated. This data report will be provided to USEPA after 90 days of receipt of validated data and will include validation results.

A sediment chemistry data report will be prepared once all of the sediment chemistry results (including all Phase III data) have been validated. This data report will be provided to USEPA after 90 days of receipt of validated data and will include validation results.

Notes:

- ^a Analytical MDLs and QLs are those documented in validated methods.
- ^b Achievable MDLs and QLs are limits that an individual laboratory can achieve when performing a specific analytical method. Reporting limits will be adjusted accordingly when reduced sample volume is available.
- ^c The Passive Sampler Blank will only be analyzed for dissolved organic carbon and ammonia.

BHC = benzene hexachloride
CAS = Chemical Abstracts Service
HpCDD = heptachlorodibenzo-*p*-dioxin
HpCDF = heptachlorodibenzofuran
HxCDD = hexachlorodibenzo-*p*-dioxin
HxCDF = hexachlorodibenzofuran
MDL = method detection limit
mg/L = milligrams per liter
mV = millivolts
NA = not applicable
ng/L = nanograms per liter
OCDD = octachlorodibenzo-*p*-dioxin
OCDF = octachlorodibenzofuran
PCBs = polychlorinated biphenyls
PeCDD = pentachlorodibenzo-*p*-dioxin
PeCDF = pentachlorodibenzofuran
PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans

pg/L = picograms per liter
QL = quantitation limit
SIM = selective ion monitoring
SOP = Standard Operating Procedure
SU = Standard Units
TAL = Target Analyte List
TCDD = tetrachlorodibenzo-*p*-dioxin
TCDF = tetrachlorodibenzofuran
TEPH = total extractable petroleum hydrocarbon
TOC = total organic carbon
µg/L = micrograms per liter

QAPP Worksheet #15-2 (UFP-QAPP Manual Section 2.8.1): Reference Limits and Evaluation – Sediment (continued)

Notes:

- ^a Study Action Levels are presented in Appendix C.
- ^b Analytical MDLs and QLs are those documented in validated methods.
- ^c Achievable MDLs and QLs are limits that an individual laboratory can achieve when performing a specific analytical method.

AVS/SEM = acid volatile sulfide/simultaneously extracted metals
BHC = benzene hexachloride
CAS = Chemical Abstracts Service
DDD = dichlorodiphenyldichloroethane
DDE = dichlorodiphenyldichloroethylene
DDT = dichlorodiphenyltrichloroethane
HpCDD = heptachlorodibenzo-*p*-dioxin
HpCDF = heptachlorodibenzofuran
HxCDD = hexachlorodibenzo-*p*-dioxin
HxCDF = hexachlorodibenzofuran
MDL = method detection limit
mg/kg = milligrams per kilogram
NA = not applicable
ng/kg = nanograms per kilogram
OCDD = octachlorodibenzo-*p*-dioxin
OCDF = octachlorodibenzofuran
ORP = oxidation reduction potential
PCBs = polychlorinated biphenyls
PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans
PeCDD = pentachlorodibenzo-*p*-dioxin
PeCDF = pentachlorodibenzofuran
QL = quantitation limit
SIM = selective ion monitoring
SOP = Standard Operating Procedure
TAL = Target Analyte List
TCDD = tetrachlorodibenzo-*p*-dioxin
TCDF = tetrachlorodibenzofuran
TEPH = total extractable petroleum hydrocarbon
TOC = total organic carbon
µg/kg = micrograms per kilogram
µmoles/g = micromoles per gram
% = percent

QAPP Worksheet #15-3 (UFP-QAPP Manual Section 2.8.1): Reference Limits and Evaluation – Tissue

QAPP Worksheet #15-3 (UFP-QAPP Manual Section 2.8.1): Reference Limits and Evaluation – Tissue (continued)

Matrix: Tissue
Analytical Group: Miscellaneous
Concentration Level: Low
Analytical Method/SOP Reference: L-1, L-21

Analyte	CAS Number	Study Action Level ^a mg/kg	Project Quantitation Limit mg/kg	Analytical Method ^b		Achievable Laboratory Limits ^c	
				MDLs mg/kg	Method QLs mg/kg	MDLs mg/kg	QLs mg/kg
% Lipids	% Lipids	--	NA	NA	NA	NA	NA
% Moisture	% Moist	--	NA	NA	NA	NA	NA

Notes:

- ^a Study action levels are based on human health criteria for fish tissue consumption (USEPA RSLs for fish ingestion, November 2013), except where noted, provided in Appendix C.
- ^b Analytical MDLs and QLs are those documented in validated methods.
- ^c Achievable MDLs and QLs are limits that an individual laboratory can achieve when performing a specific analytical method.
- ^d Fish tissue threshold is based on the lowest NOAEL or LOAEL TRVs from the literature. Threshold value was obtained from Table 2 of the Lower Passaic River Restoration Project QAPP.
- ^e Back-calculated NOAEL mammal threshold is derived by back-calculating tissue thresholds from literature based on dietary NOAEL TRVs using species-specific exposure parameters (i.e., body weight and sediment ingestion rate). The value is the lowest of back-calculated threshold for mink or river otter. NOAEL TRVs derived from toxicity studies were expressed as daily dietary doses normalized for body weight and converted to a concentration in ingested prey tissue using the equation presented in Footnote f. Threshold value was obtained from Table 2 of the Lower Passaic River Restoration Project QAPP.
- ^f Back-calculated NOAEL bird threshold is derived by back-calculating tissue thresholds from literature based on NOAEL TRVs using species-specific parameters. The value is the lowest of back-calculated thresholds for shorebirds, eagle, merganser, or osprey. NOAEL TRVs derived from toxicity studies were expressed as daily dietary doses normalized for body weight. To convert these NOAEL TRVs to a concentration in ingested prey tissue, the following equation was used:
 $C_{Tis} = (Dose \times BW) / DFC$
Where: C_{Tis} = concentration in prey tissue (mg/kg ww)
Dose = NOAEL TRV (mg/kg BW/day)
BW = body weight (kg)
DFC = daily food consumption rate (kg ww/day)
- Threshold value was obtained from Table 2 of the Lower Passaic River Restoration Project QAPP.
- ^g Decapod tissue threshold is based on the lowest NOAEL or LOAEL TRVs from the literature. Threshold value was obtained from Table 2 of the Lower Passaic River Restoration Project QAPP.

BHC = benzene hexachloride
CAS = Chemical Abstracts Service
DDD = dichlorodiphenyldichloroethane
DDE = dichlorodiphenyldichloroethylene
DDT = Dichlorodiphenyltrichloroethane
HpCDD = heptachlorodibenzo-*p*-dioxin
HpCDF = heptachlorodibenzofuran
HxCDD = hexachlorodibenzo-*p*-dioxin
HxCDF = hexachlorodibenzofuran
LOAEL = lowest-observed-adverse-effect level
MDL = method detection limit
mg/kg = milligrams per kilogram
NA = not applicable

QAPP Worksheet #15-3 (UFP-QAPP Manual Section 2.8.1): Reference Limits and Evaluation – Tissue (continued)

Notes (continued):

ng/kg = nanograms per kilogram
NOAEL = no-observed-adverse-effect level
OCDD = octachlorodibenzo-*p*-dioxin
OCDF = octachlorodibenzofuran
PCBs = polychlorinated biphenyls
PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans
PeCDD = pentachlorodibenzo-*p*-dioxin
PeCDF = pentachlorodibenzofuran
pg/g = picograms per gram
QL = quantitation limit
SIM = selective ion monitoring
SOP = Standard Operating Procedure
TAL = Target Analyte List
TCDD = tetrachlorodibenzo-*p*-dioxin
TCDF = tetrachlorodibenzofuran
TRV = toxicity reference value
µg/kg = micrograms per kilogram
% = percent
-- = not available

QAPP Worksheet #15-4 (UFP-QAPP Manual Section 2.8.1): Reference Limits and Evaluation – Porewater (continued)

Matrix: Porewater
Analytical Group: Miscellaneous
Concentration Level: Low
Analytical Method/SOP Reference: L-44, L-43, and L-42

Analyte	CAS Number	Study Action Level	Project Quantitation Limit	Analytical Method ^a		Achievable Laboratory Limits ^b	
				MDLs	Method QLs	MDLs	QLs
DOC	DOC	---	---	0.5 mg/L	1.0 mg/L	0.5 mg/L	1.0 mg/L
Ammonia	766-41-7	---	---	0.05 mg/L	0.1 mg/L	0.05 mg/L	0.1 mg/L
Total Sulfide	18496-25-8	---	---	0.054 mg/L	0.16 mg/L	0.054 mg/L	0.16 mg/L

Notes:

- ^a Analytical MDLs and QLs are those documented in validated methods.
- ^b Achievable MDLs and QLs are limits that an individual laboratory can achieve when performing a specific analytical method. Reporting limits will be adjusted accordingly when reduced sample volume is available.
- ^c Estimated MDL for passive sampling is based on laboratory MDL values and the assumption of equilibrium of porewater with the passive sampler. DLs are not reported for compounds for which the passive sampling approach has not been developed (using PE or POM) due to the high uncertainty with the measurement.

BHC = benzene hexachloride
CAS = Chemical Abstracts Service
DOC = dissolved organic carbon
HpCDD = heptachlorodibenzo-*p*-dioxin
HpCDF = heptachlorodibenzofuran
HxCDD = hexachlorodibenzo-*p*-dioxin
HxCDF = hexachlorodibenzofuran
MDL = method detection limit
mg/L = milligrams per liter
NA = not applicable
ng/L = nanograms per liter
OCDD = octachlorodibenzo-*p*-dioxin
OCDF = octachlorodibenzofuran
PCBs = polychlorinated biphenyls
PeCDD = pentachlorodibenzo-*p*-dioxin
PeCDF = pentachlorodibenzofuran
PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans
pg/L = picograms per liter
QL = quantitation limit
SIM = selective ion monitoring
SOP = Standard Operating Procedure
TAL = Target Analyte List
TCDD = tetrachlorodibenzo-*p*-dioxin
TCDF = tetrachlorodibenzofuran
µg/L = micrograms per liter

QAPP Worksheet #16 (UFP-QAPP Manual Section 2.8.2): Project Schedule/Timeline Table

Activities	Organization	Dates (MM/DD/YY)		Deliverable	Deliverable Due Date
		Anticipated Date(s) of Initiation	Anticipated Date of Completion		
Preparation of SQT and Porewater Sampling and Analysis QAPP	ARCADIS	February 2015	April 2015 (Draft)	NBSA SQT QAPP	August 31, 2015 (Final; estimated)
Field Readiness Review	ARCADIS	Prior to field work	Prior to field work	Participant sign-off sheet	August 27, 2015 ^{a,b}
Laboratory Readiness Review	FTS	Prior to field work	Prior to field work	Participant sign-off sheet	August 27, 2015 ^{a,b}
SQT Sampling	ARCADIS	September 2015	2.5 weeks after initiation	All samples submitted to laboratories	September 30, 2015 ^a
Porewater Passive Sampler Sampling	University of Maryland Baltimore County	After conclusion of field work	3 months after sample delivery	All samples submitted to laboratories	December 31, 2015 ^a
Sediment Toxicity Testing	EA Engineering, Science, and Technology, Inc.	After conclusion of field work	28 days after initiation	Data Packages	October 28, 2015
Benthic Invertebrate Community Analyses	Normandeau Associates, Inc.	After conclusion of field work	90 days after sample delivery	Data Packages	December 31, 2015
Bioaccumulation Testing	EA Engineering, Science, and Technology, Inc.	After conclusion of field work	28 days after initiation	Laboratory Report; All samples submitted to laboratories	October 28, 2015
Chemical Laboratory Analysis	Vista, eurofins/Lancaster Laboratories, eurofins/Frontier Global Sciences, Val Associates, TestAmerica	After start of field work	4 weeks after receipt of samples	Data Packages	January 29, 2016 ^a
Data Validation	FTS	Upon receipt of laboratory data	4 weeks after receipt of laboratory data	Data Verification/ Validation Report	February 26, 2016 ^a
Data Usability Assessment	FTS	Upon completion of data validation	4 weeks after completion of data validation	Data Quality and Usability Assessment Report	March 25, 2016 ^a
Preparation of SQT and Porewater Passive Sampler Data Reports	ARCADIS	Upon completion and receipt of all Phase III validated data	4 months after completion and receipt of validated data	Phase III Data Report(s)	July 2016 ^a

^a Deliverable due date is based on an estimated field start date of September 14, 2015. Tierra will stay in close communication with USEPA Region 2 regarding the actual start date.

^b Deliverable for Readiness Review is anticipated on August 27, 2015, or earlier.

QAPP Worksheet #17 (UFP-QAPP Manual Section 3.1.1): Sampling Design and Rationale

Describe and provide a rationale for choosing the sampling approach (e.g., grid system, biased statistical approach):

A sediment sample size of 30 was determined, statistically, to be adequate to evaluate relationships among chemical concentrations, amphipod survival, and the various benthic metrics in the NBSA. Using Systat® 12.0, a sample size of 29 was calculated as the minimum size necessary to detect a significant correlation coefficient when the true correlation is 0.5 or greater, with 95% confidence and 80% power. In comparison, sample size of 28 was used to collect SQT samples from each sub-basin in the New York/New Jersey (NY/NJ) Harbor Estuary by USEPA's Regional Environmental Monitoring and Assessment Program (REMAP) (USEPA 2003). As such, the proposed sample size of 30 is consistent with that utilized by USEPA in the past within Newark Bay.

SQT analyses (sediment chemistry, toxicity testing with *L. plumulosus*, and benthic invertebrate community analysis) and porewater analyses will be conducted at all 30 selected stations. Bioaccumulation tests will be conducted at a subset of eight stations.

Twenty-three surface sediment sampling stations were selected from locations near where human-sediment contact could potentially occur. Ten of the 23 sampling stations selected to support the BHHRA overlapped with a sampling location already identified for SQT and BERA purposes; therefore, only 13 additional surface sediment stations have been added. These 13 additional sampling locations will only be analyzed for sediment chemistry. Data collected from these stations will be used to assess the impact of direct human contact with sediment (dermal and incidental sediment ingestion), which could potentially occur during recreational and occupational activities. This additional shoreline sample frequency is roughly equivalent to that used by the CPG in sampling human accessible areas in the LPRRP between 2005 and 2012.

Describe the sampling design and rationale in terms of what matrices will be sampled, what analytical groups will be analyzed and at what concentration levels, the sampling locations, the number of samples to be collected, and the sampling frequency [Refer to Figure 1 and Worksheet No. 18 for details]:

The sediment collected under this QAPP will be used in the Baseline Human Health and Ecological Risk Assessment (BHHERA) for the following purposes:

1. Analyses to support the SQT
 - Surface sediment chemistry analyses
 - Benthic invertebrate community analyses
 - Laboratory toxicity testing (from which survival and growth metrics of benthic invertebrates will be developed)
2. Additional lines of evidence to support the baseline ecological risk assessment (BERA)
 - Laboratory bioaccumulation tests using invertebrates from which tissue will be collected for chemical analyses
 - Porewater chemical analyses and estimates using passive sampling methods
3. Surface sediment chemistry analyses to support the baseline human health risk assessment (BHHRA)

Matrices

Surface sediment samples will be collected from 43 sampling stations and submitted to the analytical laboratories for chemical analysis. Surface sediment chemistry samples are being collected to support the SQT and the BHHRA.

Passive samplers will be deployed in the laboratory in site sediment from each of the 30 SQT sampling stations. Hydrophobic chemicals (i.e., PCBs, SVOC SIM, PCDDs/PCDFs, pesticides) will be sampled using polyethylene (PE) and polyoxymethylene (POM) passive samplers, and dialysis samplers will be used for the sampling of metals and other inorganics. Porewater samples will be collected from each station and submitted to the analytical laboratories for chemical analysis. Porewater chemical analysis results are being collected to support the BERA.

Tissue samples of the polychaete worm (*Nereis virens*) will be collected from 8 stations as part of the bioaccumulation testing component of the SQT program. At the conclusion of the laboratory-based bioaccumulation test, tissue samples will be submitted to the analytical laboratories for chemical analysis.

QAPP Worksheet #17 (UFP-QAPP Manual Section 3.1.1): Sampling Design and Rationale (continued)

Analytical Groups and Concentration Levels

The chemical analyses planned for surface sediment samples collected in support of the SQT program and in support of the BHHRA are consistent with those analyses performed under the CPG LPRRP and Phases I and II of the Newark Bay Sediment Investigations. The chemical analyses planned for porewater samples collected in support of the BERA include the same chemical analyses performed under the CPG LPRRP and Phases I and II of the Newark Bay Sediment Investigations with the exception of VOCs, cyanide, Aroclor PCBs, wet chemistry (ammonia, total sulfide, total phosphorus, and total kjeldahl nitrogen), total organic carbon, and physical parameters (grain size and percent moisture). The chemical analyses planned for tissue samples resulting from the bioaccumulation study are consistent with the parameters analyzed in tissue under the CPG LPRRP. Concentration levels for all analyses are expected to be low. The table below lists the specific analytical groups planned for analysis for each matrix.

Analyte Group	Concentration Levels	Sediment	Porewater	Tissue
Dioxins/Furans	Low	X	X	X
Congener PCBs	Low	X	X	X
Aroclor PCBs	Low	X		X
Metals	Low	X	X	X
Mercury	Low	X	X	X

Sampling Locations, Numbers of Samples, and Sampling Frequency

For logistical purposes only, the NBSA has been divided into three geographic zones: Newark Bay North, Newark Bay Central, and Newark Bay South. The North, Central, and South zones will not be incorporated into the risk assessment, but will be used to generally check the spatial adequacy of planned sampling. Except in the Intertidal Areas, stations were stratified by geographic

QAPP Worksheet #17 (UFP-QAPP Manual Section 3.1.1): Sampling Design and Rationale (continued)

zone and randomly located. In each zone, four Intertidal Areas were selected for sampling. Of the 30 locations identified for sampling within the NBSA, 12 stations are located in Newark Bay North, eight stations are located in Newark Bay Central, and 10 stations are located in Newark Bay South. The 30 sediment sampling stations proposed for the SQT program were selected using a random, stratified, gridded sample design based on the size (areal extent) of the geographic zone available for sampling, as described in detail in the *Technical Memorandum: Proposed Risk Assessment Field Sampling and Analysis Program – Newark Bay Study Area* (ARCADIS 2015; Draft, not approved by USEPA).

In addition to the geographic zones, Newark Bay is composed of several geomorphic areas, three of which are important for sampling considerations: Intertidal Areas, Subtidal Flats, and Transitional Slopes. While the Navigation and Port Channels may provide overwintering habitat for aquatic organisms, many of these areas are regularly dredged for maintenance purposes. As such, the focus of the proposed sampling program is on the shallower Subtidal Flats, Transitional Slopes, and Intertidal Areas of the NBSA. Areas that were historically dredged but are no longer maintained are also included in the sampling program. These include the former Navigation Channel areas in Newark Bay North and south of Shooters Island. Twelve of the 30 stations are located in the Intertidal Areas 14 are located in the Subtidal Flats (including 3 stations located in the formerly dredged area in Newark Bay North), and four stations are located in the Transitional Slopes.

SQT analyses (sediment chemistry, toxicity testing with *L. plumulosus*, and benthic invertebrate community analysis) will be conducted at all 30 stations. As additional lines of evidence to support the BERA, porewater chemistry analyses will be conducted at all 30 locations and bioaccumulation tests will be conducted at a subset of eight stations (two stations in the Subtidal Flats, one station in the Transitional Slopes, and 5 stations in the Intertidal Areas). The table below provides a summary of the analyses to be conducted to support the SQT, BERA, and BHHRA and the numbers of stations for each analysis.

Proposed Analysis	Number of Subtidal Flat Stations*	Number of Transitional Slope Stations	Number of Intertidal Stations	Total Number of Sampling Stations
SQT Analyses				
Sediment Chemistry (BHHRA)	14	4	12**	30
Toxicity Testing with <i>L. plumulosus</i> (10-day)	14	4	12	30
Toxicity Testing with <i>L. plumulosus</i> (28-day)	14	4	12	30
Benthic Invertebrate Community Analysis	14	4	12	30
Additional Lines of Evidence to Support the BERA				
Bioaccumulation Study (<i>N. virens</i>)	2	1	5	8
Porewater Chemistry	14	4	12	30
Additional sediment chemistry for BHHRA	--	--	13	13

Notes:

* Includes formerly dredged areas in Newark Bay North.

** 10 of the twelve intertidal stations are being used to support the BHHRA

In support of the BHHRA, 23 surface sediment sampling stations were selected from locations near where human-sediment contact could potentially occur. Ten of the 23 sampling stations selected to support the BHHRA overlapped with a sampling location already identified for SQT and BERA purposes; therefore, only 13 additional surface sediment stations have been added. These 13 additional sampling locations will only be analyzed for sediment chemistry. Data collected from these stations will be used to assess the impact of direct human contact with sediment (dermal and incidental sediment ingestion), which could potentially occur during recreational and occupational activities.

QAPP Worksheet #17 (UFP-QAPP Manual Section 3.1.1): Sampling Design and Rationale (continued)

The table below provides a summary of the proposed sampling stations and the planned analyses for each sampling station.

Station	Geographic Zone	Geomorphic Area	Porewater Chemistry	Sediment Chemistry	Benthic Invertebrate Community Analysis	Sediment Toxicity (<i>L. pumilus</i>) (10-day)	Sediment Toxicity (<i>L. pumilus</i>) (28-day)	Bioaccumulation Test (<i>N. virens</i>)	BHRA Sediment Chemistry

Passive Sampler Blank	DOC	Low	L-44	80	120 mL, G	4°C	28 days
Field Blank	TEPH - purgeables	Low	L-33	120	3x 40 mL vial, G no headspace	4°C, HCl to pH <2	14 days
Field Blank	TEPH - extractables/alkanes	Low	L-16	1 L	1 L, G	4°C, HCl to pH <2	7 days to extraction, 40 days until analysis
Field Blank	Hexavalent Chromium	Low	L-17	70	250 mL, P	4°C	24 hours
Field Blank	pH	Low	L-19	100	250 mL, P	4°C	24 hours
Field Blank	Total Phosphorus	Low	L-23	500	500 mL, G	4°C, H ₂ SO ₄ to pH <2	24 hours
Field Blank	Total Kjeldahl Nitrogen	Low	L-24	500			
Field/Passive Sampler Blank	Ammonia	Low	L-26	200	500 mL, P	4°C, H ₂ SO ₄ to pH <2	28 days

See the last page of Worksheet #19-1 for a description of footnotes.

QAPP Worksheet #19-1 (UFP-QAPP Manual Section 3.1.2): Analytical SOP Requirements – Field/Rinse/Trip Blanks (continued)

Notes:

- ^a Surface water samples are not planned for collection during this sampling program but this worksheet has been provided to describe field, rinse, passive sampler and trip blank sample collection requirements only. The passive sampler blank for organics will be an unused PE and/or POM sampler placed in DI water. The PE and/or POM sampler will be agitated in the DI water for the same amount of time as the PE and/or POM samplers are agitated in the sediment slurry. At the end of the testing period, the PE and/or POM strips will be shipped to the laboratories for chemical analysis. The passive sampler blank for inorganics will be an unused dialysis bag filled with DI water. The DI water will be allowed to sit in the dialysis bag for the same amount of time as the dialysis bags are exposed to the sediment and under the same light and temperature conditions. At the end of the testing period, the dialysis bags filled with DI water will be shipped to the laboratories for chemical analysis.
- ^b Analytical methods are as specified in Worksheet #23-1.
- ^c These are minimum sample volume requirements for a single sample analysis. Extra volume will be needed in order to fulfill quality control sample requirements, such as matrix spike/matrix spike duplicate and/or to provide contingency volume for analysis or breakage. For glass containers, if additional volume is available, a second container will be sent to provide additional volume.
- ^d Samples for analyses having identical container and preservation requirements may be combined in the same container. Similarly, smaller- or larger-sized sample containers than those recommended here may be used as long as the quality, container material, and preservative specifications are met, and the containers or container used will hold sufficient mass/volume to meet the minimum requirements specified.
- ^e Holding time is calculated from the date and time of sample collection, to the date and time of sample analysis (or extraction as noted).
- ^f Maximum holding times listed are based upon those stipulated in corresponding data validation guidance located in Appendix E of this Sediment Quality Triad and Porewater Sampling and Analysis QAPP.
- ^g Samples will be shipped at 4°C to the laboratory via overnight carrier on the same day they are collected. Preservation will occur at the laboratory within the specified holding time (immediately upon receipt) in order to minimize the sources of potential field contamination. Samples will be stored for a minimum of 48 hours at 4°C after preservation and prior to analysis to allow the acid to completely dissolve the metals adsorbed on the container walls.

°C = degrees Celsius

DOC = dissolved organic carbon

G = amber glass

H₂SO₄ = sulfuric acid

HCl = hydrochloric acid

HNO₃ = nitric acid

L = liter

mL = milliliters

NaOH = sodium hydroxide

P = plastic

PCB = polychlorinated biphenyl

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans

SIM = selective ion monitoring

SOP = standard operating procedure

TAL = Target Analyte List

TEPH = total extractable petroleum hydrocarbons

TOC = total organic carbon

QAPP Worksheet #19-2 (UFP-QAPP Manual Section 3.1.2): Analytical SOP Requirements – Sediment

Matrix	Analytical Group	Concentration Level	Analytical and Preparation Method/SOP Reference ^a	Sample Mass (g) ^b	Containers (number and type) ^c	Preservation Requirements (chemical, temperature, light protected)	Maximum Holding Time (preparation/analysis) ^{d,e}
Sediment	PCDDs/PCDFs ^f	Low	L-1	30	8.8 oz, G	4°C	30 days to extraction, 40 days until analysis
Sediment	PCB Congeners ^f	Low	L-2	30	8.8 oz, G	4°C	30 days to extraction, 40 days until analysis

QAPP Worksheet #20-1 (UFP-QAPP Manual Section 3.1.2): Sediment Quality Control Sample Summary (continued)

Notes:

- ^a Laboratory performance evaluation samples are part of the planned project quality control program. However, these samples are not listed here, as the quality control samples will be administered separately from sample collection control tasks. Ongoing PE samples will be submitted to the appropriate laboratory according to the following protocol. SDGs containing split samples (shared with USEPA) will have a PE sample submitted at a frequency of 1 for each SDG. USEPA will reserve the right to choose the split samples from the available samples collected. SDGs that do not contain USEPA split samples will have 1 PE sample submitted for laboratory analysis for every 40 field samples collected. Ongoing PE sample analyses are independent of the pre-program performance evaluation study.
- ^b Referenced from the Analytical SOP References Table (Worksheet #23).
- ^c Assumes MS/MSD will be collected at a rate of one (MS) and one (MSD) per up to 20 samples or per SDG (whichever is more frequent) for all constituents, except cyanide, which will have one MS and laboratory duplicate per up to 20 samples collected or per SDG, whichever is more frequent. Grain size, % moisture, and pH will have laboratory duplicates, no MS/MSD, ORP will have two laboratory duplicates.
- ^d This value excludes MS/MSD.
- ^e The number of trip blanks may vary depending upon the duration of sampling. One trip blank is required to be transported with each shipment of samples when volatile organic compounds, mercury, or methylmercury will be analyzed.

AVS/SEM = acid volatile sulfide/simultaneously extracted metals

MS = matrix spike

MSD = matrix spike duplicate

NA = not applicable

ORP = oxidation reduction potential

PCB = polychlorinated biphenyl

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans

SDG = sample delivery group

SIM = selective ion monitoring

SOP = Standard Operating Procedure

TAL = Target Analyte List

TEPH = total extractable petroleum hydrocarbons

TOC = total organic carbon

% = percent

QAPP Worksheet #20-2 UFP-QAPP Manual Section 3.1.2): Tissue Quality Control Sample Summary^{a, b}

Notes:

- ^a Referenced from the Analytical SOP References Table (Worksheet #23).
- ^b Assumes MS/MSD will be collected at a rate of one (MS) and one (MSD) up to 20 samples or per SDG (whichever is more frequent) for all constituents.
- ^c This value excludes MS/MSD.
- ^d The number of trip blanks may vary depending upon the duration of sampling. One trip blank is required to be transported with each shipment of samples when mercury or methylmercury will be analyzed.

MS = matrix spike
 MSD = matrix spike duplicate
 NA = not applicable
 SDG = sample delivery group
 SOP = Standard Operating Procedure

QAPP Worksheet #21 (UFP-QAPP Manual Section 3.1.2): Project Sampling SOP References Table

SOP Reference Number	Title, Revision Date, and/or Number	Originating Organization	Equipment Type	Modified for Project Work? (Y/N)	Comments
1	Locating Sample Points Using Hand-Held Global Positioning System (April 2015), Revision 0	ARCADIS	Hand-held GPS unit	Y*	Appendix B
2	Positioning (April 2015), Revision 0	ARCADIS	Trimble Geo XT (or similar unit) with related cable and power supply	Y*	Appendix B
3	Decontamination (April 2015), Revision 0	ARCADIS	Scoops, bowls, spoons, scales, and any equipment that comes into contact with sediment	Y*	Appendix B
4	Management and Disposal of Residuals (April 2015), Revision 0	ARCADIS	Open-top drums, storage racks, and insulated coolers	Y*	Appendix B
5	Containers, Preservation, Handling, and Tracking of Samples for Analysis (April 2015), Revision 0	ARCADIS	COC forms, custody seals, sample containers, packaging supplies, and coolers	Y*	Appendix B
6	Sediment Sample Collection (April 2015), Revision 0	ARCADIS	Sediment grab samplers, hand auger, and/or corer and fathometer (or weighted demarcated line)	Y*	Appendix B
7	Measuring Surface Water Quality (April 2015), Revision 0	ARCADIS	Multi-parameter water quality meter (YSI 6000 or equivalent)	Y	Appendix B

QAPP Worksheet #21 (UFP-QAPP Manual Section 3.1.2): Project Sampling SOP References Table (continued)

SOP Reference Number	Title, Revision Date, and/or Number	Originating Organization	Equipment Type	Modified for Project Work? (Y/N)	Comments
8	Documenting Field Activities (April 2015), Revision 0	ARCADIS	Wireless recording device (e.g., laptop), bound waterproof logbooks, electronic field data forms, camera	Y*	Appendix B
9	Data Management (April 2015), Revision 0	ARCADIS		Y*	Appendix B

Note: * Indicates that these SOPs are modified versions of previously approved SOPs; either from Newark Bay Study Area Phase I/II Sediment Investigations, Newark Bay Study Area Phase III Risk Assessment Investigations, or CPG's Lower Passaic River SOPs.

QAPP Worksheet #22 (UFP-QAPP Manual Section 3.1.2.4): Field Equipment Calibration, Maintenance, Testing, and Inspection Table

Field Equipment ^a	Calibration Activity	Maintenance Activity	Testing Activity	Inspection Activity	Frequency	Acceptance Criteria	Corrective Action	Responsible Person	SOP Reference ^a
GPS receiver	The GPS receiver is calibrated automatically using satellite signals each time it is powered on.	Keep one set of fresh batteries available at all times. Keep dirt and dust away from GPS receiver.	Vessel will be stationed at the check point to verify GPS position with known land-survey coordinates.	Confirm there are no cracks in the unit and that the antenna has not been damaged.	Each time unit is powered on.	GPS receiver is suitable for use if it is reporting coordinates, indicating it is receiving signals from three independent GPS satellites.	If unit will not obtain a coordinate lock, move to an unobstructed location. If no unobstructed location is available, consider recording position at nearby unobstructed location and measuring horizontal offset that can be used to correct the measured position later.	FS or designee	1
Fathometer	The meter is calibrated automatically using built-in tests each time it is powered on.	Keep one set of fresh batteries available at all times. Keep dirt and dust away from fathometer.	Run built-in tests to verify unit is in working order	Confirm there are no cracks in the unit and that the fathometer is in good condition.	Each time unit is powered on.	Meter is undamaged and has no error messages.	Repair and replace as necessary.	FS or designee	6
Sediment grab samplers	NA	Decontamination	NA	Inspect for physical damage that may compromise effectiveness of sampler.	Daily, prior to use.	Sampler is undamaged.	Repair damage, if possible, or replace trap as necessary.	FS or designee	6
Sieves	NA	Decontamination	NA	Inspect for physical damage that may compromise effectiveness of sieve.	Daily, prior to use.	Sieve is undamaged.	Repair damage, if possible, or replace sieve as necessary.	FS or designee	6

QAPP Worksheet #22 (UFP-QAPP Manual Section 3.1.2.4): Field Equipment Calibration, Maintenance, Testing, and Inspection Table (continued)

Field Equipment^a	Calibration Activity	Maintenance Activity	Testing Activity	Inspection Activity	Frequency	Acceptance Criteria	Corrective Action	Responsible Person	SOP Reference^a
Multi-parameter water quality meter (YSI 6000 or equivalent)	The meter is calibrated daily when in use.	Keep one set of fresh batteries available at all times. Protect probes from damage.	Calibrate against known standards.	Confirm that the o-ring is installed and in good condition.	Daily, prior to use.	Meter is undamaged and has no error messages.	Recalibrate, repair, and replace as necessary.	FS or designee	7

Notes:

^a Refer to Project Sampling SOP References table (Worksheet #21).

FS = Field Supervisor

GPS = global positioning system

NA = not applicable

SOP = standard operating procedure

SOP = Standard Operating Procedure

QAPP Worksheet #25 (UFP-QAPP Manual Section 3.2.3): Analytical Instrument and Equipment Maintenance, Testing, and Inspection

All analytical instrumentation/equipment must be inspected, maintained, and tested. Procedures for inspection, maintenance, and testing of laboratory instruments and equipment are provided in the laboratory's quality assurance (QA) manuals and associated laboratory Standard Operating Procedures (SOPs). Appropriate QA manuals and SOPs can be obtained and submitted to the U.S. Environmental Protection Agency for review prior to mobilization.

Documentation of inspections, maintenance, and testing of laboratory instruments and equipment will include details of observed problems, corrective measures, routine maintenance, and instrument repair, including information regarding the repair and the individual who performed the repair.

At a minimum, major instruments will be backed up by comparable (if not equivalent) instrument systems to avoid unscheduled downtime. An inventory of spare parts will also be available to minimize equipment/instrument downtime.

QAPP Worksheet #26 (UFP-QAPP Manual Section 3.3): Sample Handling System

Sample Collection, Packaging, and Shipment	Analytical Chemistry Sediment Samples
Sample collection (personnel/organization):	ARCADIS U.S., Inc.
Sample packaging (personnel/organization):	ARCADIS U.S., Inc.
Coordination of shipment (personnel/organization):	ARCADIS U.S., Inc.
Type of shipment/carrier:	Carrier (FedEx, UPS, or equivalent) from field for samples sent to TestAmerica and Vista Analytical; Private courier from field for samples sent to Eurofins/Lancaster
Sample Collection, Packaging, and Shipment	Sediment Samples for Porewater Analysis/Passive Sampling
Sample collection (personnel/organization):	ARCADIS U.S., Inc.
Sample packaging (personnel/organization):	ARCADIS U.S., Inc.
Coordination of shipment (personnel/organization):	ARCADIS U.S., Inc.
Type of shipment/carrier:	Refrigerated truck from field
Sample Collection, Packaging, and Shipment	Sediment Samples for Toxicity and Bioaccumulation Testing
Sample collection (personnel/organization):	ARCADIS U.S., Inc.
Sample packaging (personnel/organization):	ARCADIS U.S., Inc.
Coordination of shipment (personnel/organization):	EA Engineering, Science, and Technology, Inc.
Type of shipment/carrier:	Private courier from field
Sample Collection, Packaging, and Shipment	Samples for Benthic Invertebrate Community Analysis
Sample collection (personnel/organization):	ARCADIS U.S., Inc.
Sample packaging (personnel/organization):	ARCADIS U.S., Inc.
Coordination of shipment (personnel/organization):	Normandeau Associates, Inc.
Type of shipment/carrier:	Private courier from field
Sample Collection, Packaging, and Shipment	Porewater Samples/Passive Samplers for Chemistry Analysis
Sample collection (personnel/organization):	University of Maryland Baltimore County
Sample packaging (personnel/organization):	University of Maryland Baltimore County
Coordination of shipment (personnel/organization):	University of Maryland Baltimore County
Type of shipment/carrier:	Carrier (FedEx, UPS, or equivalent) from University of Maryland Baltimore County
Sample Receipt and Analysis	
Sample receipt (personnel/organization):	Contact at appropriate laboratory
Sample custody and storage (personnel/organization):	Contact at appropriate laboratory
Sample preparation (personnel/organization):	Contact at appropriate laboratory
Sample determinative analysis (personnel/organization):	Contact at appropriate laboratory
Sample Archiving	
Field sample storage (number of days from sample collection):	1 year until Tierra, in consultation with USEPA, authorizes disposal
Sample extract/digestate storage (number of days from extraction/digestion):	1 year until Tierra, in consultation with USEPA, authorizes disposal
Sample Disposal	
Personnel/organization:	Tierra in accordance with the USEPA-approved Waste Characterization QAPP (Tierra 2011)
Number of days from analysis:	1 year until Tierra, in consultation with USEPA, authorizes disposal

QAPP Worksheet #27 (UFP-QAPP Manual Section 3.3.3): Sample Custody Requirements

Field Sample Custody Procedures (sample collection, packaging, shipment, and delivery to laboratory):

Sediment samples for chemistry analysis and bulk sediment samples sent to laboratories for toxicity, bioaccumulation, and porewater analysis will be collected in the field, processed, and packaged for transport to the appropriate laboratories. Benthic community samples will be sieved in the field, amended with preservative, and shipped to the appropriate laboratory for analysis. Sediment samples for chemistry analysis will be placed in coolers with ice or other means of keeping the samples cold (as appropriate) for shipment. Sediment samples for chemistry analysis will be shipped via standard carrier (FedEx or equivalent) to TestAmerica and Vista Analytical via carrier, and sediment samples for chemistry analysis by Eurofins/Lancaster will be transported via private courier. Bulk sediment samples sent to laboratories for toxicity and bioaccumulation, and samples for benthic invertebrate community analysis, will be transported via private courier coordinated by the respective laboratories. Bulk sediment samples sent to UMBC for porewater analysis will be shipped via refrigerated truck. The Standard Operating Procedures (SOP) for collecting the sediment samples are discussed in further detail in Appendix B.

For sediment samples being shipped from the field for chemistry analysis, the original, signed chain-of-custody (COC) forms will be placed in a sealable plastic bag, sealed, and taped to the inside lid of the cooler. Package sealing tape will be wrapped completely around the cooler. On each side of the cooler, a "This Side Up" arrow label will be attached, a "Handle with Care" label will be attached to the top of the cooler, and the cooler will be sealed with a custody seal in two locations. An example COC form and custody seal are provided in Appendix B.

Similarly, porewater dialysis bags and passive samplers (PE and/or POM) will be placed in coolers with ice or other means of keeping the samples cold (as appropriate) for shipment to the appropriate laboratories for extraction and chemistry analysis. The original, signed chain-of-custody (COC) forms will be placed in a sealable plastic bag, sealed, and taped to the inside lid of the cooler. Package sealing tape will be wrapped completely around the cooler. On each side of the cooler, a "This Side Up" arrow label will be attached, a "Handle with Care" label will be attached to the top of the cooler, and the cooler will be sealed with a custody seal in two locations. An example COC form and custody seal are provided in Appendix B.

For samples that may be shipped without coolers (e.g., bulk sediment for porewater testing), the sample containers will have custody seals affixed and the COCs will accompany the shipment in a manner consistent with the requirements of chain of custody.

Laboratory Sample Custody Procedures (receipt of samples, archiving, disposal):

Each contracted laboratory will have a laboratory-specific SOP that details the procedures used to document sample receipt and custody within the laboratory. The following procedures must be addressed in the laboratory custody SOP:

- Each laboratory must have a designated sample custodian who accepts custody of the samples at the time of delivery to the laboratory and verifies that the information on the sample labels matches the information on the COC. The sample custodian must sign and date all appropriate receiving documents and note any discrepancies in sample documentation, as well as the condition of the samples at the time of receipt.
- Once the samples have been accepted by the laboratory, checked, and logged in, they must be maintained in accordance with laboratory custody and security requirements as outlined in the laboratory Quality Management Plan.
- To confirm traceability of samples during the analytical process, the laboratory will assign a sample identification (ID) number based on procedures outlined in the laboratory Quality Management Plan or laboratory SOP.
- The following procedures, at a minimum, must be documented by the laboratory:
 - Sample extraction/preparation
 - Sample analysis
 - Data reduction
 - Data reporting

Laboratory personnel are responsible for sample custody until the samples are returned to the sample custodian.

QAPP Worksheet #27 (UFP-QAPP Manual Section 3.3.3): Sample Custody Requirements (continued)

When sample analysis and QC procedure are completed, any remaining sample must be stored in accordance with contractual terms. Data sheets, custody documents, and all other laboratory records must be retained in accordance with contractual agreements.

Final Evidence Files

Laboratory records, including all field- and laboratory-initiated COCs and other sample receiving records, sample preparation and analysis records, and the final data package, become part of the laboratory final evidence file and must be retained as required by the contractual agreement. An original copy of the data package and associated electronic deliverable must be provided to the investigative organization in accordance with the contractual agreement and will be retained by the investigative organization, including associated field records and other related correspondence.

Sample Identification Procedures:

The sediment samples will be identified with the site name, time, date, sampling location, and field crew initials. Unique alphanumeric ID numbers will be assigned to each sample depending on the analysis. The sample identification schematic is as follows and as discussed in SOP 5 (Appendix B):

The first two characters will be "NB" to identify the project area (Newark Bay).

The second two characters will be "03" to identify that this sample was collected as part of Phase III.

The next seven characters will define the sample type:

- SED-CHM = chemistry
- SED-TOX = toxicity
- SED-BIO = bioaccumulation
- SED-COM = benthic community
- SED-POR = porewater
- TIS-BIO = tissue from bioaccumulation testing

The final three characters are the station number. As samples 1 through 135 have been collected as part of Phases I, II and III, locations collected as part of this continued Phase III sampling event will start at 136.

For example, a sediment chemistry sample collected from station 136 would be labeled: "NB03SED-CHM136." If more than one sample is collected from the same sampling station, a designation of "A, B, C, etc." will be used to identify the difference.

Chain-of-Custody Procedures:

COC procedures are documented in detail in Appendix B and summarized briefly below. Samples are considered to be in custody if they are: 1) in the custodian's possession or view, 2) in a secured place (locked) with restricted access, or 3) in a container and secured with an official seal(s), such that the sample cannot be reached without breaking the seal(s). Custody procedures as defined in Appendix B will be used for all samples throughout the collection and transport process. Custody procedures will be initiated at sample collection. An electronic COC form will accompany samples to the analytical laboratory. Each person who has custody of the samples will sign the COC form and confirm that the samples are not left unattended unless properly secured.

The Field Supervisor (FS) will be responsible for all sample tracking and custody procedures for samples in the field. The FS will be responsible for final sample inventory and will maintain sample custody documentation. The FS will also complete COC forms prior to removing samples from the sampling area. At the end of each day, and prior to transfer, COC entries will be made for all samples. Information on the labels will be checked against

QAPP Worksheet #27 (UFP-QAPP Manual Section 3.3.3): Sample Custody Requirements (continued)

sample log entries, and samples will be recounted. COC forms will accompany all samples. The COC forms will be signed at each point of transfer. Copies of all COC forms will be retained and included as appendices to quality assurance/quality control reports and data reports. Samples will be shipped in sealed coolers or in other secured manner that maintains required shipping conditions.

The contracted laboratories will confirm that COC forms are properly signed upon receipt of the samples and will note questions or observations concerning sample integrity on the COC forms. The laboratory will contact the Facility Coordinator and Project Quality Assurance Coordinator immediately if discrepancies are discovered between the COC forms and the sample shipment upon receipt.

QAPP Worksheet #28-1a (UFP-QAPP Manual Section 3.4): Sediment Field Quality Control Samples

Matrix	Sediment
Analytical Group	PCDDs/PCDFs, PCB Congeners, TAL Metals, Mercury, Methylmercury, Butyltins, Chlorinated Herbicides, Semivolatile Organics, Semivolatile Organics (SIM), Aroclor PCBs, Pesticides, Volatile Organics, Cyanide, TOC, TEPH - purgeables, TEPH - extractables/alkanes, Hexavalent Chromium, pH, % Moisture, Total Sulfide, Total Phosphorus, Total Kjeldahl Nitrogen, AVS/SEM, Ammonia, Grain Size, ORP, Titanium
Concentration Level	Low
Sampling SOP	SOP-6
Analytical Method/SOP Reference	L-1, L-2, L-3, L-4, L-5, L-6, L-7, L-8, L-9, L-10, L-11, L-12, L-13, L-15, L-16, L-17, L-18, L-20, L-22, L-23, L-24, L-25, L-26, L-27, L-28, L-29, L-33
Field Sampling Organization	ARCADIS
Analytical Organization	Vista Analytical, eurofins/Lancaster Laboratories, eurofins/Frontier Global Sciences, TestAmerica, Val Associates
Number of Samples Collected	See Worksheet #20

QC Sample	Frequency Number	Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Field Duplicates	1 per sample delivery group, not to exceed 1 per 20 field samples per matrix and per method	Associated data will be critically assessed to determine the impact to data quality	Precision	RPD \leq 50% when target is detected in both field duplicate samples at $>$ 5X PQL, or concentrations differ by less than 2X the PQL when detects are $<$ 5X PQL for both field duplicate samples
Trip Blank	1 trip blank will be included with each shipment of samples which contains volatile organics, mercury or methylmercury field samples	Associated data will be critically assessed to determine the impact to data quality	Accuracy/Bias Contamination	No target compounds \geq PQL
Field Blank ^a	1 per decontamination event, not to exceed 1 per day. Note field blanks will not be collected for pH, % moisture, total sulfide, AVS/SEM, grain size or ORP analytical groups.	Associated data will be critically assessed to determine the impact to data quality	Accuracy/Bias Contamination	No target compounds \geq PQL

See the page after Worksheet 28-1c for description of footnotes.

QAPP Worksheet #28-1b (UFP-QAPP Manual Section 3.4): Tissue Field Quality Control Samples

Matrix	Tissue
Analytical Group	PCDDs/PCDFs, PCB Congeners, TAL Metals, Mercury, Methylmercury, Butyltins, Semivolatile Organics, Semivolatile Organics (SIM), Aroclor PCBs, Pesticides, % Lipids, % Moisture, Titanium
Concentration Level	Low
Sampling SOP	SOP-6
Analytical Method/SOP Reference	L-1, L-2, L-3, L-4, L-5, L-6, L-8, L-9, L-10, L-11, L-21, L-29, L-34, L-37
Sampling Organization	ARCADIS
Analytical Organization	EA, Vista Analytical, eurofins/Lancaster Laboratories, eurofins/Frontier Global Sciences, TestAmerica
Number of Samples Collected	See Worksheet #20

QC Sample	Frequency Number	Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Rinse Blank ^b	1 per decontamination event, not to exceed 1 per day. Note rinse blanks will not be collected for % lipids or % moisture analytical groups.	Associated data will be critically assessed to determine the impact to data quality	Accuracy/Bias Contamination	No target compounds \geq PQL
Trip Blank	1 trip blank will be included with each shipment of samples which contains mercury or methylmercury field samples.	Associated data will be critically assessed to determine the impact to data quality	Accuracy/Bias Contamination	No target compounds \geq PQL
Field Duplicates	1 per sample delivery group, not to exceed 1 per 20 field samples per matrix and per method	Associated data will be critically assessed to determine the impact to data quality	Precision	RPD \leq 50% when target is detected in both field duplicate samples at $>$ 5X PQL, or concentrations differ by less than 2X the PQL when detects are $<$ 5X PQL for both field duplicate samples

See the page after Worksheet 28-1c for description of footnotes.

QAPP Worksheet #28-1c (UFP-QAPP Manual Section 3.4): Porewater Field Quality Control Samples

Matrix	Porewater			
Analytical Group	PCDDs/PCDFs, PCB Congeners, TAL Metals, Titanium, Mercury, Methylmercury, Semivolatile Organics (SIM), Pesticides, Dissolved Organic Carbon, Ammonia, Total Sulfide			
Concentration Level	Low			
Sampling SOP	SOP-6			
Analytical Method/SOP Reference	L-1, L-2, L-3, L-29, L-4, L-5, L-9, L-11, L-40, L-41, L-44, L-43, L-42			
Sampling Organization	ARCADIS			
Analytical Organization	University of Maryland Balitmore County, Vista Analytical, eurofins/Lancaster Laboratories, eurofins/Frontier Global Sciences			
Number of Samples Collected	See Worksheet #20			
QC Sample	Frequency Number	Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Passive Sampler Blank	1 per extraction type	Associated data will be critically assessed to determine the impact to data quality	Accuracy/Bias Contamination	No target compounds >PQL
Trip Blank	1 trip blank will be included with each shipment of samples which contains mercury or methylmercury field samples.	Associated data will be critically assessed to determine the impact to data quality	Accuracy/Bias Contamination	No target compounds ≥PQL
Field Duplicates	1 per sample delivery group, not to exceed 1 per 20 field samples per matrix and per method	Associated data will be critically assessed to determine the impact to data quality	Precision	RPD ≤50% when target is detected in both field duplicate samples at >5X PQL, or concentrations differ by less than 2X the PQL when detects are <5X PQL for both field duplicate samples

See the page after Worksheet 28-1c for description of footnotes.
Quality control samples are defined on the notes page following Worksheet 28-1.

QAPP Worksheets #28-1a-c (UFP-QAPP Manual Section 3.4): Field Quality Control Samples

Notes:

- ^a Field blanks will only be collected in association with sediment and porewater.
- ^b Rinse blanks will be prepared by the analytical laboratory in association with homogenization of tissue samples only.

AVS/SEM = acid volatile sulfide/simultaneously extracted metals
ORP = oxidation reduction potential
PCBs = polychlorinated biphenyls
PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/dibenzofurans
PQL= project quantitation limit
QC = quality control

RPD = relative percent difference
SIM = selective ion monitoring
SOP = Standard Operating Procedure
TAL = Target Analyte List
TEPH = total extractable petroleum hydrocarbon
TOC = total organic carbon

Definition of Terms:

Field Blank

Sample collected by pouring de-ionized water or solvent, whichever is appropriate for the constituents of interest, over the decontaminated sediment sample collection and processing equipment in the field. Field blanks will be prepared for each decontamination event at a frequency not to exceed one per day and will be traceable to the sediment samples collected and processed on that day or associated with that decontamination event, whichever is applicable. Field blanks check for potential contamination prior to sampling, sample processing and the transportation of sediment samples.

Field Duplicate

Co-located samples to be collected as separate, discrete samples, which are assigned separate and discrete sample numbers. Field duplicates for analytical sediment chemistry are not to be homogenized together, as this would defeat the purpose of the field duplicate. Field duplicates will be collected at a frequency of 1 field duplicate per sample delivery group not to exceed 1 per 20 field samples per matrix and per method. Field duplicates for passive samplers will be collected by placing twice the number of PE/POM samplers or dialysis bags in the same beaker for a given sample. Passive sampler (i.e., porewater) field duplicates will be collected from the same samples as the sediment field duplicates.

Rinse Blank

Sample collected by pouring de-ionized water or solvent, whichever is appropriate for the constituents of interest, over the decontaminated homogenization equipment being used in the analytical laboratory. Rinse blanks will be prepared for each decontamination event at a frequency not to exceed one per day and will be traceable to the tissue samples prepared on that day or associated with that decontamination event, whichever is applicable. Rinse blanks check primarily for potential contamination that may be caused by reuse of decontaminated homogenization equipment, however, contamination from the sampling process and transportation will also be captured.

Trip Blank

Sample matrices that are as free of volatile analytes as possible and transported with the samples to the laboratory without being opened. Trip blanks will be shipped with each shipment of samples that contains any volatile organics, mercury or methylmercury field samples. Trip blanks check for potential contamination during transport and storage before analysis.

QAPP Worksheets #28-1a-c (UFP-QAPP Manual Section 3.4): Field Quality Control Samples (continued)

Passive Sampler Blank

The passive sampler blank for organics will be an unused PE and/or POM sampler placed in DI water. The PE and/or POM sampler will be agitated in the DI water for the same amount of time as the PE and/or POM samplers are agitated in the sediment slurry. At the end of the testing period, the PE and/or POM strips will be shipped to the laboratories for chemical analysis.

The passive sampler blank for inorganics will be an unused dialysis bag filled with DI water. The DI water will be allowed to sit in the dialysis bag for the same amount of time as the dialysis bags are exposed to the sediment and under the same light and temperature conditions. At the end of the testing period, the dialysis bags filled with DI water will be shipped to the laboratories for chemical analysis.

QAPP Worksheet #28-2a (UFP-QAPP Manual Section 3.4): Blank Quality Control Samples (continued)

Notes:

^a A batch is defined as a group of up to 20 samples of the same matrix, prepared at the same time, using the same procedure.

DCAA = 2,4-dichlorophenylacetic acid

OPR = ongoing precision and recovery

PCBs = polychlorinated biphenyls

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/dibenzofurans

PQL = project quantitation limit

QC = quality control

SIM = selective ion monitoring

SOP = Standard Operating Procedure

TAL = Target Analyte List

TEPH = total extractable petroleum hydrocarbons

TOC = total organic carbon

% = percent

QAPP Worksheet #28-2b (UFP-QAPP Manual Section 3.4): Sediment Laboratory Quality Control Samples

Matrix	Sediment
Analytical Group	PCDDs/PCDFs
Concentration Level	Low
Sampling SOP	SOP-6

QAPP Worksheet #28-2b (UFP-QAPP Manual Section 3.4): Sediment Laboratory Quality Control Samples (continued)

Notes:

- ^a A batch is defined as a group of up to 20 samples of the same matrix, prepared at the same time, using the same procedure.
- ^b Ongoing PE standard samples will be submitted to the appropriate laboratory according to the following protocol. SDGs containing split samples (shared with USEPA) will have a PE sample submitted at a frequency of 1 for each SDG. USEPA will reserve the right to choose the split samples from the available samples collected. SDGs that do not contain USEPA split samples will have one PE sample submitted for laboratory analysis for every 40 field samples collected. Ongoing PE sample analyses are independent of the pre-program performance evaluation study.
- ^c Non-split SDGs – are SDGs that do not contain samples split for analysis between Tierra and USEPA laboratories
Split SDGs – are SDGs that contain samples which have been split for analysis between Tierra and USEPA laboratories.

AVS/SEM = acid volatile sulfide/simultaneously extracted metals

DCAA = 2-4-Dichlorophenylacetic acid

mV = millivolts

ORP = Oxidation Reduction Potential

PCBs = polychlorinated biphenyls

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans

PE = performance evaluation

PQL = project quantitation limit

QC = quality control

RPD = relative percent difference

SDG = sample delivery group

SIM = selective ion monitoring

SOP = Standard Operating Procedure

TAL = Target Analyte List

TEPH = total extractable petroleum hydrocarbons

TOC = total organic carbon

USEPA = U.S. Environmental Protection Agency

% = percent

Sampling Organization	ARCADIS
Analytical Organization	EA, eurofins/Lancaster Laboratories
No. of Samples Collected	See Worksheet #20

QC Sample	Frequency/Number	Method/SOP QC Acceptance Limits	Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Laboratory Duplicate	1 per analytical batch ^a	RPD ≤20%	The laboratories should review their protocols and correct any that may have caused exceedance of the QC acceptance limits. If sufficient field sample is available, re-analyze affected samples. If insufficient sample is available, re-analyze extracts. Qualify data as needed.	Precision - Lab	RPD ≤20%

Notes:

- ^a A batch is defined as a group of up to 20 samples of the same matrix, prepared at the same time, using the same procedure.
- ^b Ongoing PE samples will be submitted to the appropriate laboratory according to the following protocol. SDGs containing split samples (shared with USEPA) will have a PE sample submitted at a frequency of 1 for each SDG. USEPA will reserve the right to choose the split samples from the available samples collected. SDGs that do not contain USEPA split samples will have one PE sample submitted for laboratory analysis for every 40 field samples collected. Ongoing PE sample analyses are independent of the pre-program performance evaluation study.
- ^c Non-split SDGs – are SDGs that do not contain samples split for analysis between Tierra and USEPA laboratories.
 Split SDGs – are SDGs that contain samples which have been split for analysis between Tierra and USEPA laboratories.

EA = EA Engineering, Science, and Technology, Inc.

% = percent

PCBs = polychlorinated biphenyls

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans

PE = performance evaluation

PQL = project quantitation limit

QC = quality control

RPD = relative percent difference

SDG = sample delivery group

SIM = selective ion monitoring

SOP = Standard Operating Procedure

TAL = Target Analyte List

USEPA = U.S. Environmental Protection Agency

QAPP Worksheet #28-2d (UFP-QAPP Manual Section 3.4): Porewater Laboratory Quality Control Samples (continued)

Matrix	Porewater				
Analytical Group	Pesticides				
Concentration Level	Low				
Sampling SOP	SOP-6				
Analytical Method/SOP Reference	L-11, L-40				
Field Sampling Organization	ARCADIS				
Analytical Organization	University of Maryland Baltimore County, Vista Analytical				
No. of Samples Collected	See Worksheet #20				
QC Sample	Frequency/Number	Method/SOP QC Acceptance Limits	Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Method Blanks	1 per extraction batch ^a	No target compounds ≥PQL	The laboratories should review their protocols and correct any that may have caused exceedance of the QC acceptance limits. If sufficient field sample is available, re-extract and re-analyze affected samples. If insufficient sample is available, re-analyze extracts. Qualify data as needed.	Accuracy/Bias Contamination	No target compounds ≥PQL
Instrument Blanks	1 per 12 hour sequence	No target compounds ≥PQL	The laboratories should review their protocols and correct any that may have caused exceedance of the QC acceptance limits. Re-analyze affected sample extracts. Qualify data as needed.	Accuracy/Bias Contamination	No target compounds ≥PQL

See the last page of Worksheet #28-2d for a description of footnotes.

QAPP Worksheet #28-2d (UFP-QAPP Manual Section 3.4): Porewater Laboratory Quality Control Samples (continued)

Matrix	Porewater
Analytical Group	Pesticides
Concentration Level	Low
Sampling SOP	SOP-6
Analytical Method/SOP Reference	L-11, L-40
Field Sampling Organization	ARCADIS
Analytical Organization	University of Maryland Baltimore County, Vista Analytical
No. of Samples Collected	See Worksheet #20

QC Sample	Frequency/Number	Method/SOP QC Acceptance Limits	Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Initial Calibration	At initial setup or when corrective action is taken, which may change calibration per L-11	Per L-11	The laboratory must follow all corrective actions required by L-11.	Accuracy/Bias	Per L-11
Calibration Verification	Prior to every 12-hour period, but following Column Performance Solution and at end of 12-hour period per L-11	Per L-11	The laboratory must follow all corrective actions required by L-11.	Accuracy/Bias	Per L-11
Labeled Compound Spike	26 per sample	Per L-11	The laboratories should review their protocols and correct any that may have caused exceedance of the QC acceptance limits. Refer to L-11.	Accuracy/Bias	Per L-11
Labeled Internal Standards	5 per sample	Per L-11	The laboratories should review their protocols and correct any that may have caused exceedance of the QC acceptance limits. Refer to L-11.	Accuracy/Bias	Per L-11

See the last page of Worksheet #28-2d for a description of footnotes.

QAPP Worksheet #28-2d (UFP-QAPP Manual Section 3.4): Porewater Laboratory Quality Control Samples (continued)

Matrix	Porewater				
Analytical Group	Dissolved Organic Carbon				
Concentration Level	Low				
Sampling SOP	SOP-6				
Analytical Method/SOP Reference	L-41, L-44				
Field Sampling Organization	ARCADIS				
Analytical Organization	University of Maryland Baltimore County, eurofins/Lancaster Laboratories				
No. of Samples Collected	See Worksheet #20				
QC Sample	Frequency/Number	Method/SOP QC Acceptance Limits	Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Continuing Calibration Blanks	Every 10 injections, follows the CCV	No target compounds \geq PQL	The laboratories should review their protocols and correct any that may have caused exceedance of the QC acceptance limits. Re-analyze affected samples. Qualify data as needed.	Accuracy/Bias Contamination	No target compounds \geq PQL
Initial Calibration	At initial setup, and then every 30 days after.	Corr Coeff. \geq 0.995	The laboratory must follow all corrective actions required by L-44	Accuracy/Bias	Corr Coeff. \geq 0.995
Initial Calibration Verification	Following calibration	90-110%	Investigate and recalibrate, if necessary, per L-44	Accuracy/Bias	90-110%
Continuing Calibration Verification	Every 10 injections	90-110%	The laboratories should review their protocols and correct any that may have caused exceedance of the QC acceptance limits. Re-analyze affected samples. Qualify data as needed.	Accuracy/Bias	90-110%
Quality Control Sample	1 per analytical batch	% Recovery 86-114	The laboratories should review their protocols and correct any that may have caused exceedance of the QC acceptance limits. If sufficient field sample is available, re-analyze affected samples. If insufficient sample is available, re-analyze extracts. Qualify data as needed.	Accuracy/Bias	% Recovery 86-114

See the last page of Worksheet #28-2d for a description of footnotes.

QAPP Worksheet #28-2d (UFP-QAPP Manual Section 3.4): Porewater Laboratory Quality Control Samples (continued)

Matrix	Porewater				
Analytical Group	Ammonia				
Concentration Level	Low				
Sampling SOP	SOP-6				
Analytical Method/SOP Reference	L-41, L-43				
Field Sampling Organization	ARCADIS				
Analytical Organization	University of Maryland Baltimore County, eurofins/Lancaster Laboratories				
No. of Samples Collected	See Worksheet #20				
QC Sample	Frequency/Number	Method/SOP QC Acceptance Limits	Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria

QAPP Worksheet #28-2d (UFP-QAPP Manual Section 3.4): Porewater Laboratory Quality Control Samples (continued)

Notes:

^a A batch is defined as a group of up to 20 samples of the same matrix, prepared at the same time, using the same procedure.

DCAA = 2,4-dichlorophenylacetic acid

PCBs = polychlorinated biphenyls

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/dibenzofurans

PQL = project quantitation limit

QC = quality control

SIM = selective ion monitoring

SOP = Standard Operating Procedure

SVOC = Semivolatile Organic Compounds

TAL = Target Analyte List

% = percent

QAPP Worksheet #29-1 (UFP-QAPP Manual Section 3.5): Project Documents and Records

QAPP Worksheet #29-2 (UFP-QAPP Manual Section 3.5): Required Analytical Chemistry Data Deliverable Elements (Continued)

Notes:

() = form number; refer to CLP SOW forms if CLP is used
AA = atomic absorption
AVS/SEM = acid volatile sulfide/simultaneously extracted metals
CLP = Contract Laboratory Program
CRDL = contract required detection limit
DOC = dissolved organic carbon
GC = gas chromatography
GC/MS = gas chromatography/mass spectrometry
GPC = gel permeation chromatography
HERB = herbicides
ICP = inductively coupled plasma
ICPMS = inductively coupled plasma mass spectrometry
Inorg. = inorganic
MS/MSD = matrix spike/matrix spike duplicate
Org. = organic
ORP = oxidation reduction potential
PCBs = polychlorinated biphenyls
PCDDs/PCDFs = polychlorinated dibenzo-p-dioxins/polychlorinated dibenzofurans
Pest = pesticides
QC = quality control
RIC = Reconstructed total ion chromatogram
RT = retention time
SIM = selective ion monitoring
SIPCs = selected ion current profiles
SOW = statement of work
TAL = Target Analyte List
TEPH = total petroleum hydrocarbons
TOC = total organic carbon
% = percent

QAPP Worksheet #29-3 (UFP-QAPP Manual Section 3.5): Standard Laboratory Data Qualifiers

The laboratory qualifiers and their stated definitions provided below will be used by the laboratories exclusively when reporting sample results for this SQT and Porewater Sampling and Analysis Quality Assurance Project Plan^a.

Qualifier	Description
B	Inorganics – The reported value was obtained from an instrument reading that was less than the project quantitation limit (PQL). Organics – The associated analyte was also detected in the method blank.
D	The organic analyte was quantitated from a diluted analysis.
E	Inorganics – The reported value is estimated because of the presence of an interference. Organics – The associated compound concentration exceeded the calibration range of the instrument.
J	Organic data indicated the presence of a compound that meets the identification criteria; the result is below the PQL but above the method detection limit (MDL) or estimated detection limit (EDL), where appropriate.
N	The inorganic analysis is associated with a spike sample not within control limits.
P	The percent difference between the primary and confirmation column for pesticide/Aroclor analyses is greater than 25%.
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
*	The inorganic duplicate analysis was not within the established quality control limit.
S	Inorganics - The reported value was determined by Method of Standard Additions (MSA).
+	Inorganics - Correlation coefficient for MSA is less than 0.995.
W	Inorganics - The post-digestion spike for furnace atomic absorption analysis is out of control.
I	The laboratory indicated the presence of an interference during the sample analysis.

Other Data Reporting Requirements:

Only analytical data that are verified/validated (see Worksheets #34, #35, and #36) will be reported.

- Organic analytes detected below the PQL, but above the MDL/EDL, will be reported with a "J" flag, and organic analytes detected below the PQL and MDL/EDL as non-detects at the PQL.
- Inorganic analytes detected below the PQL, but above the MDL, will be reported with a "B" flag, and inorganic analytes detected below the PQL and MDL as non-detects at the MDL.

Notes:

^a A final deliverable will be provided with standard laboratory qualifiers consistent with U.S. Environmental Protection Agency Electronic Deliverable Region 2 MEDD Format Reference Manual (www.epa.gov/region02/superfund/medd.html).

QAPP Worksheet #29-4 (UFP-QAPP Manual Section 3.5): Example Format for Electronic Loading of Laboratory Files

A final deliverable will be provided with standard laboratory qualifiers consistent with U.S. Environmental Protection Agency Electronic Deliverable Region 2 MEDD Format Reference Manual (www.epa.gov/region02/superfund/medd.html).

QAPP Worksheet #29-5 (UFP-QAPP Manual Section 3.5): Laboratory Documentation and Records for Toxicity Testing, Bioaccumulation Study, and Benthic Invertebrate Community Analysis

Toxicity Testing and Bioaccumulation Study

Copies of the raw data sheets with statistical analyses and the Report Quality Assurance Record will be included as attachments. Additionally, the following logs are maintained that contain information related to the testing:

- Chronological Sample Log
- Test Log
- Lab Dilution Water Log
- Meter Calibration Log
- Balance Calibration Log
- Thermometer Calibration Log
- Standard Preparation Log
- Sample Disposal Log
- Organism Acquisition Log
- Reference Toxicant Control Chart Log

Individual data packets will be prepared for each test type. The datasheets and form numbers that will be included with each test type can be found below:

10-Day Leptocheirus plumulosus Form List

- EA Form #ATS-T12 – Sediment Toxicity Test Observation Data Sheet
- EA Form #ATS-T13 – Toxicity Test Water Quality Data Sheet (Day 0-6, new dilutions)
- EA Form #ATS-T14 – Toxicity Test Water Quality Data Sheet (Day 1-7, old dilutions)
- EA Form #ATS-T16 – Toxicity Test Water Quality Data Sheet (Day 8-14, old dilutions)
- EA Form #ATS-T28 – Sediment Toxicity Test Set-Up Bench Sheet
- EA Form #ATS-T29 – Toxicology Laboratory Bench Sheet
- EA Form #ATS-T30 – Toxicology Laboratory Bench Sheet - Organism Loading Record

28-Day Leptocheirus plumulosus Form List

- EA Form #ATS-T12 – Sediment Toxicity Test Observation Data Sheet
- EA Form #ATS-T13 – Toxicity Test Water Quality Data Sheet (Day 0-6, new dilutions)
- EA Form #ATS-T14 – Toxicity Test Water Quality Data Sheet (Day 1-7, old dilutions)
- EA Form #ATS-T15 – Toxicity Test Water Quality Data Sheet (Day 7-13, new dilutions)
- EA Form #ATS-T16 – Toxicity Test Water Quality Data Sheet (Day 8-14, old dilutions)
- EA Form #ATS-T17 – Toxicity Test Water Quality Data Sheet (Day 14-20, new dilutions)
- EA Form #ATS-T18 – Toxicity Test Water Quality Data Sheet (Day 15-21, old dilutions)
- EA Form #ATS-T19 – Toxicity Test Water Quality Data Sheet (Day 21-27, new dilutions)
- EA Form #ATS-T20 – Toxicity Test Water Quality Data Sheet (Day 22-28, old dilutions)
- EA Form #ATS-T29 – Toxicology Laboratory Bench Sheet
- EA Form #ATS-T30 – Toxicology Laboratory Bench Sheet - Organism Loading Record
- EA Form #ATS-T31 – Toxicology Laboratory Bench Sheet - Feeding Record
- EA Form #ATS-T32 – Toxicology Laboratory Bench Sheet - Renewal Record
- EA Form #ATS-T46 – Weight Data

QAPP Worksheet #29-5 (UFP-QAPP Manual Section 3.5): Laboratory Documentation and Records for Toxicity Testing, Bioaccumulation Study, and Benthic Invertebrate Community Analysis (cont.)

28-Day Neries virens Form List

- EA Form #ATS-T12 – Sediment Toxicity Test Observation Data Sheet
- EA Form #ATS-T13 – Toxicity Test Water Quality Data Sheet (Day 0-6, new dilutions)
- EA Form #ATS-T14 – Toxicity Test Water Quality Data Sheet (Day 1-7, old dilutions)
- EA Form #ATS-T16 – Toxicity Test Water Quality Data Sheet (Day 8-14, old dilutions)
- EA Form #ATS-T18 – Toxicity Test Water Quality Data Sheet (Day 15-21, old dilutions)
- EA Form #ATS-T20 – Toxicity Test Water Quality Data Sheet (Day 22-28, old dilutions)
- EA Form #ATS-T29 – Toxicology Laboratory Bench Sheet
- EA Form #ATS-T30 – Toxicology Laboratory Bench Sheet - Organism Loading Record
- EA Form #ATS-T32 – Toxicology Laboratory Bench Sheet - Renewal Record

Benthic Invertebrate Community Analysis

The following documents and/or records will be maintained to support during the benthic invertebrate community analysis:

- Chain-of-Custody Forms (one for each shipment)
- Laboratory Log-in Forms (from USEPA RBP manual – one for each shipment)
- Analytical Request Form (one for each shipment)
- Sample Processing (tracking) Form (one for each sample; contains QC data)
- Laboratory Benthic Log (tracking of each sample)
- Quality Control Log – Identification
- Quality Control Worksheet (details of QC results for Identification)
- Storage Sheet (storage of vialled identified specimens, if a year or more is required) – OR a Chain-of-Custody Form, if samples are returned to the client
- Keypunching Request Form (submittal of raw data to Technical Data Processing for keypunching)
- Keypunching/Metrics Computation Quality Control Log

QAPP Worksheet #30 (UFP-QAPP Manual Section 3.5): Analytical Services

QAPP Worksheet #32 (UFP-QAPP Manual Section 4.1.2): Assessment Findings and Corrective Action Responses (continued)

Assessment Type	Nature of Deficiencies Documentation	Individual(s) Notified of Findings (Name, Title, Organization)	Time frame of Notification	Nature of Corrective Action Response Documentation	Individual(s) Receiving Corrective Action Response (Name, Title, and Organization)	Time frame for Response
Data Validation ^a	Validation Reports	All of those listed above as impacted	40 days after receipt of laboratory and field deliverables	Resubmission of missing or corrected documents	Carlie Thompson Facility Coordinator Tierra Solutions, Inc., Eugenia Naranjo Remedial Project Manager USEPA Region 2	1 week after request for completion/correction
Data Verification ^b	Verification Reports	All of those listed above as impacted	40 days after receipt of laboratory and field deliverables	Resubmission of missing or corrected documents	Carlie Thompson Facility Coordinator Tierra Solutions, Inc., Eugenia Naranjo Remedial Project Manager USEPA Region 2	1 week after request for completion/correction
Field Sampling Technical Systems Audit	Audit Report/ Corrective Action Form	Kavin Gandhi Field Supervisor ARCADIS U.S., Inc.	1 week after audit is complete	Audit Report/ Corrective Action Form	Carlie Thompson Facility Coordinator Tierra Solutions, Inc.	Immediate

Notes:

- ^a All data collected will undergo full data validation (with the exception of grain size, percent moisture, and oxidation reduction potential) as outlined in Worksheet #36. Grain size, percent moisture, and oxidation reduction potential data will be verified per standard operating procedure.
- ^b Benthic invertebrate community analysis, toxicity testing (10-day and 28-day), and bioaccumulation testing will undergo full data verification as outlined in Worksheet #11.

QMP = quality management plan
USEPA = U.S. Environmental Protection Agency

QAPP Worksheet #33 (UFP-QAPP Manual Section 4.2): QA Management Reports

Type of Report	Frequency (e.g., daily, weekly, monthly, quarterly, annually)	Projected Delivery Date(s)	Person(s) Responsible for Report Preparation (Title and Organizational Affiliation)	Report Recipient(s) (Title and Organizational Affiliation)
Field Sampling Technical Systems Audit Reports	1 per audit conducted	Within 30 days of audit completion	Angela Gatchie Quality Assurance Coordinator Field & Technical Services	Carlie Thompson Facility Coordinator Tierra Solutions, Inc.
Internal Field Audit Report	1 per audit conducted	Within 30 days of audit completion	Jamie Combes Project Manager ARCADIS U.S., Inc.	Carlie Thompson Facility Coordinator Tierra Solutions, Inc.
Data Validation Reports	1 per sample delivery group, per analytical group	Within 60 days of receipt of final deliverables in the sample delivery group	Angela Gatchie Quality Assurance Coordinator Field & Technical Services	Carlie Thompson Facility Coordinator Tierra Solutions, Inc. Eugenia Naranjo Remedial Project Manager USEPA Region 2
Data Verification Reports	1 per report	Within 60 days of receipt of final deliverables from each laboratory	Angela Gatchie Quality Assurance Coordinator Field & Technical Services	Carlie Thompson Facility Coordinator Tierra Solutions, Inc. Eugenia Naranjo Remedial Project Manager USEPA Region 2
Data Usability Assessment Report	1 after completion of validation task	Within 60 days of validation completion	Angela Gatchie Quality Assurance Coordinator Field & Technical Services	Carlie Thompson Facility Coordinator Tierra Solutions, Inc. Eugenia Naranjo Remedial Project Manager USEPA Region 2

Notes:

All data collected will undergo full data validation (with the exception of grain size, percent moisture, and oxidation reduction potential data) as outlined in Worksheet #36. Grain size, percent moisture, and oxidation reduction potential data collected will be verified per standard operating procedure.

USEPA = U.S. Environmental Protection Agency

QAPP Worksheet #34 (UFP-QAPP Manual Section 5.2.1): Verification (Step I) Process

Verification Input	Action	Internal/ External	Organization Responsible for Verification
Chain of custody and shipping forms	Chain of custody/requests for analysis forms and shipping documentation will be reviewed internally upon their completion and verified against the packed sample coolers they represent. The shipper's signature on the chain of custody should be initialed by the reviewer, a copy of the chain of custody retained in the site file, and the original and remaining copies taped inside the cooler for shipment.	I/E	ARCADIS U.S., Inc. Field & Technical Services
Field notes	Field notes will be reviewed internally and placed in the project file.	I	ARCADIS U.S., Inc.
Corrective Action Reports	Corrective Action Reports (when necessary) will be verified for completeness and signed by the Facility Coordinator and Quality Assurance Coordinator. Corrective actions must also be communicated to appropriate field staff, as well as project review personnel.	I	Tierra Solutions, Inc. Field & Technical Services
Documentation of deviation from sample collection methods	Verify completeness and accuracy prior to distribution and placement in the project file. Communicate deviations to pertinent field staff, as well as project review personnel.	I	ARCADIS U.S., Inc.
Field-generated electronic data deliverables ^a	Verify completeness and accuracy prior to distribution and placement in the project file.	I	ARCADIS U.S., Inc.
Identification of QC samples	Verify completeness and accuracy prior to distribution and placement in the project file.	I	ARCADIS U.S., Inc.
Observed climatological condition recordings	Verify completeness and accuracy prior to distribution and placement in the project file.	I	ARCADIS U.S., Inc.
Equipment decontamination records	Verify completeness and accuracy prior to distribution and placement in the project file.	I	ARCADIS U.S., Inc.
Sampling equipment calibration logs	Verify completeness and accuracy prior to distribution and placement in the project file.	I	ARCADIS U.S., Inc.
Field measurements documentation	Verify completeness and accuracy prior to distribution and placement in the project file.	I	ARCADIS U.S., Inc.

See the last page of Worksheet #34 for a description of footnotes.

QAPP Worksheet #34 (UFP-QAPP Manual Section 5.2.1): Verification (Step I) Process (continued)

Verification Input	Action	Internal/ External	Organization Responsible for Verification
Sample condition upon receipt and storage records	Chain of custody/requests for analysis forms and shipping documentation will be reviewed upon cooler receipt. The contents of each cooler will be checked against information provided on the chain of custody/request for analysis forms. Cooler temperatures and specified sample preservation will also be verified and recorded.	I/E	eurofins/Lancaster Laboratories Vista Analytical eurofins/Frontier Global Sciences TestAmerica Val Associates EA Engineering, Science, and Technology, Inc. Normandeu Associates, Inc. University of Maryland Baltimore County
Internal laboratory chain of custody records	A complete set of chain of custody records must be produced and submitted with the data package for each SDG.	I	eurofins/Lancaster Laboratories Vista Analytical eurofins/Frontier Global Sciences TestAmerica Val Associates EA Engineering, Science, and Technology, Inc. Normandeu Associates, Inc. University of Maryland Baltimore County
Case Narrative to include the following: <ul style="list-style-type: none">• Identification of QC samples• Communication logs• Corrective action reports• Documentation of corrective action results• Documentation of laboratory method deviations• Signatures for laboratory sign-off	Verify completeness and accuracy prior to shipping the laboratory report.	I	eurofins/Lancaster Laboratories Vista Analytical eurofins/Frontier Global Sciences TestAmerica Val Associates EA Engineering, Science, and Technology, Inc. Normandeu Associates, Inc. University of Maryland Baltimore County
Laboratory data package deliverables as specified in Worksheet #29-2	All laboratory data packages will be verified by the laboratory performing the work for completeness and technical accuracy prior to shipping the laboratory report.	I	eurofins/Lancaster Laboratories Vista Analytical eurofins/Frontier Global Sciences TestAmerica Val Associates

See the last page of Worksheet #34 for a description of footnotes.

QAPP Worksheet #34 (UFP-QAPP Manual Section 5.2.1): Verification (Step I) Process (continued)

Verification Input	Action	Internal/ External	Organization Responsible for Verification
Laboratory electronic data deliverables as specified in Worksheet #29-4	All laboratory electronic data deliverables will be verified by the laboratory performing the work for completeness and accuracy prior to shipping the laboratory report.	I	eurofins/Lancaster Laboratories Vista Analytical eurofins/Frontier Global Sciences TestAmerica Val Associates
Laboratory and field data packages and electronic data deliverables as specified in Worksheets #29-2, #29-3, and #29-4	All received data packages will be verified externally for completeness according to the data verification/validation procedures specified in Worksheet #36.	E	Field & Technical Services

Notes:

^a Field-generated electronic data deliverables will be formatted and submitted in USEPA Region 2 MEDD format with the correct reference codes provided as per the USEPA Electronic Data Deliverable Valid Values Reference Manual (available at <http://www.epa.gov/region02/superfund/medd.htm>)

E = external in relation to data generator

I = internal in relation to data generator

QC = quality control

SDG = sample delivery group

USEPA = U.S. Environmental Protection Agency

QAPP Worksheet #35 (UFP-QAPP Manual Section 5.2.2): Validation (Steps IIa and IIb) Process

Step IIa/IIb	Validation Input	Description of Validation Procedure	Organization Responsible for Validation
IIa	Data Deliverables and QAPP	Confirm that all required information on sampling and analysis from data verification was provided.	Field & Technical Services
IIa	Analytes	Confirm that required lists of analytes were reported as specified in this SQT QAPP.	Field & Technical Services
IIa	Chain of Custody	Examine the traceability of the data from time of sample collection until reporting of data. Examine chain of custody records against contract, method, or procedural requirements.	Field & Technical Services
IIa	Holding Times	Identify holding time criteria and either confirm that they were met or document deviations. Confirm that samples were analyzed within holding times specified in this SQT QAPP. If holding times were not met, confirm that deviations were documented, that appropriate notifications were made (consistent with procedural requirements), and that approval to proceed was received prior to analysis.	Field & Technical Services
IIa	Sample Handling	Confirm that required sample handling, receipt, and storage procedures were followed, and that any deviations were documented. Sample preservation and temperature will specifically be evaluated and documented.	Field & Technical Services
IIa	Sampling Methods and Procedures	Establish that required sampling methods were used and that any deviations were noted. Confirm that the sampling procedures and field measurements met performance criteria and that any deviations were documented.	Field & Technical Services
IIa	Analytical Methods and Procedures	Establish that required analytical methods were used and that any deviations were noted.	Field & Technical Services
IIa	Data Qualifiers	Determine that the laboratory data qualifiers were defined and applied as specified in this SQT QAPP.	Field & Technical Services
IIa	Laboratory Transcription	Authenticate accuracy of the transcription of analytical data (i.e., laboratory notebook to reporting form or instrument to laboratory information management system).	Field & Technical Services
IIa	Standards	Determine that standards are traceable and meet contract, method, or procedural requirements.	Field & Technical Services
IIa	Communication	Establish that required communication procedures were followed by field or laboratory personnel.	Field & Technical Services
IIb	Field Duplicates	Compare results of field duplicates with criteria established in this SQT QAPP.	Field & Technical Services
IIb	Project Quantitation Limits	Determine that quantitation limits were achieved, as outlined in this SQT QAPP.	Field & Technical Services

See the last page of Worksheet #35 for a description of footnotes.

QAPP Worksheet #35 (UFP-QAPP Manual Section 5.2.2): Validation (Steps IIa and IIb) Process (continued)

Step IIa/IIb	Validation Input	Description of Validation Procedure	Organization Responsible for Validation
IIb	Confirmatory Analyses	Evaluate agreement between results of confirmatory analyses.	Field & Technical Services
IIb	Performance Criteria	Evaluate QC data against project-specific performance criteria in this SQT QAPP (i.e., evaluate quality parameters beyond those outlined in the methods).	Field & Technical Services
IIb	Analytical Methods and Procedures	Evaluate results of required QC samples and compare with acceptance criteria established in this SQT QAPP.	Field & Technical Services
IIb	Data Validation or Verification Reports	Full data validation will be performed on all analytical parameters, with the exception of grain size. Summarize deviations from methods, procedures, or contracts. Summarize outcome of comparison of data to MPC in this SQT QAPP. Include qualified data and explanation of all data qualifiers.	Field & Technical Services

Notes:

- MPC = Measurement Performance Criteria
- QC = quality control
- QL = quantitation limit
- SQT QAPP = Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan

Notes:

^a All validation and verification reference documents have been provided as appendices to this Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan.

AVS/SEM = acid volatile sulfide/simultaneously extracted metals

DOC = dissolved organic carbon

NJDEP = New Jersey Department of Environmental Protection

ORP = oxidation reduction potential

OSWER = Office of Solid Waste and Emergency Response

PCBs = polychlorinated biphenyls

PCDDs/PCDFs = polychlorinated dibenzo-*p*-dioxins/polychlorinated dibenzofurans

SOP = Standard Operating Procedure

SIM = selective ion monitoring

TAL = Target Analyte List

TEPH = total extractable petroleum hydrocarbons

TOC = total organic carbon

USEPA = U.S. Environmental Protection Agency

% = percent

QAPP Worksheet #37 (UFP-QAPP Manual Section 5.2.3): Usability Assessment

The Data Usability Assessment will be performed by Angela Gatchie, Data Manager, Field & Technical Services. Note that the Data Usability Assessment will be conducted on validated data. The results of the Data Usability Assessment will be presented in the final project report, which will be provided to U.S. Environmental Protection Agency for review and approval. The following items will be assessed and conclusions drawn based on their results.

Precision

Results of all laboratory and field duplicates will be evaluated based on the measurement performance criteria presented in Worksheets #12-1 through #12-4. A discussion will follow summarizing the results of the laboratory precision. Any conclusions about the precision of the analyses or sample collection techniques will be drawn and any limitations on the use of the data will be described.

Accuracy/Bias Contamination

Results for all laboratory method blanks and instrument blanks, as well as field rinsate equipment and trip blanks will be evaluated. The results for each analyte will be checked against the measurement performance criteria presented in Worksheets #12-1 through #12-4. A discussion will follow summarizing the results of the laboratory and field accuracy/bias. Any conclusions about the accuracy/bias of the analyses based on contamination will be drawn and any limitations on the use of the data will be described.

Overall Accuracy/Bias

The results for all matrix spike and surrogate standard spike analyses will be evaluated based on the requirements listed in Worksheets #12-1 through #12-4. A discussion will follow summarizing overall accuracy/bias. Any conclusions about the overall accuracy/bias of the analyses will be drawn and any limitations on the use of the data will be described.

Sensitivity

All analytical results reported will be evaluated to determine if adequate sensitivity was achieved. The results for each analyte will be cross-checked against the quantitation limits presented in Worksheets #15-1 through #15-4. Results for analytes that do not meet project quantitation limit criteria will be summarized. A discussion will follow detailing the results of the laboratory-sensitivity evaluation. Any conclusions about the sensitivity of the analyses will be drawn and any limitations on the use of the data will be described.

Representativeness

Representativeness is achieved through adherence to sampling and analytical procedures described in this Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan and compliance with stipulated sample holding times. After evaluation of relative compliance with specified procedures and holding times, conclusions about data representativeness will be drawn and any limitations on the use of data will be described.

QAPP Worksheet #37 (UFP-QAPP Manual Section 5.2.3): Usability Assessment (continued)

Comparability

Data comparability will be assessed through evaluation of achieved sample-specific reporting limits, units of measure, and adherence to specified analytical methodologies and field/sample collection standard operating procedures specified in this Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan. Evaluation of field procedures used will include assessment of the effects of any deviation from the established field procedures to data usability. After the evaluations are completed, conclusions about data comparability will be drawn and any limitations on the use of data will be described.

Completeness

A completeness check will be done on all of the data generated. Field and analytical completeness criteria are presented in Worksheets #12-1 through #12-4. Field and analytical completeness will be calculated for each analytical group as follows:

The field completeness will be calculated by the ratio of the number of samples received in acceptable condition by the laboratories to the number of samples planned to be collected as specified in this document. The equation for field completeness is:

$$\% \text{ Field Completeness} = \frac{\text{Number of Samples Received by Laboratories}}{\text{Total Number of Samples Planned to be Collected}} \times 100$$

The analytical completeness will be calculated by the ratio of total valid analytical data results (including estimated values) to the total number of analytical results requested on samples submitted for analysis. Valid analytical data results are defined as those that were not rejected during data validation, due to a significant quality assurance/quality control problem. The equation for analytical completeness is:

$$\% \text{ Analytical Completeness} = \frac{\text{Total Valid Analytical Data}}{\text{Analytical Data Submitted}} \times 100$$

Field Standard Operating Procedures

**Standard Operating Procedure
No. 1**

**Locating Sample Points Using
Global Positioning System**

August 2015

Revision 0

1. Purpose and Scope	3
2. Definition	3
3. Equipment and Supplies	3
4. Field Procedure	4
5. Quality Control	5

1. Purpose and Scope

The purpose of this procedure is to provide reference information regarding the collection and documentation of sample coordinates for the Newark Bay Study Area Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan using a global positioning system (GPS).

This standard operating procedure (SOP) may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s Facility Coordinator and the U.S. Environmental Protection Agency's Remedial Project Manager. The ultimate procedure employed will be documented in the field notebook.

Other SOPs will be utilized with this procedure, including:

- SOP No. 8 – Documenting Field Activities.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Definition

GPS provides navigation and positioning information from a constellation of GPS satellites operated by the U.S. Department of Defense. The system includes a control station and five monitoring locations that track each satellite. Information received by the monitoring stations is used to calculate satellite orbits and update the information sent to receivers. Satellite signals can be received by any GPS receiver on land, water, or in the air. The system incorporates a minimum of 24 satellites, which are positioned around the world, such that a minimum of four satellites are available at a given location, 24 hours a day. Personnel will use a GPS unit to collect and record sampling location coordinates. The signals received by the GPS will produce locations with sub-foot accuracy.

3. Equipment and Supplies

The following equipment list contains materials that may be needed in carrying out the procedures contained in this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment may be required, pending field conditions.

- a differential global positioning system (DGPS) unit, with sub-foot accuracy, with the antenna mounted above the location where samples will be collected (e.g. on the winch boom).

- an additional DGPS unit with equivalent accuracy as the primary unit (described above) plus an additional external antenna will be carried as a backup unit in the case of malfunction or loss
- AA or AAA batteries depending on the device
- DGPS external antennas (x2)
- equipment user's manuals
- USB cable to download information
- Field notebook.

4. Field Procedure

Power on the DGPS unit and wait several minutes for the DGPS to locate the initial position via satellite. Confirm that the date and time are correct.

Locate the coordinate system information in the main menu and verify the following settings:

1. units = feet
2. coordinate system = New Jersey State Plane (easting and northing)
3. map datum = North American Datum of 1983 (NAD83)
4. north reference = magnetic north. (Magnetic north will be used for navigational purposes; however, either magnetic or true north can be used to collect fixed coordinates. The north reference setting will be recorded in the field notebook.)

Confirm that the background map is set to North America. Record the date, time, and all relevant coordinate system information in the field notebook.

Once the unit has acquired the initial position and has indicated that it is ready, follow directions on the DGPS to begin collecting sample coordinates.

At each sampling location, allow the DGPS to receive satellite data for at least 1 minute before recording the sampling location. A minimum of three satellites is required for a three-dimensional reading, but four satellites are preferred. Save the location information at each sampling location. Record the date, time, and

easting/northing (NAD83 New Jersey State Plane) in feet for each location in the field notebook. Readings will be stored in the DGPS unit for easy downloading and also to reduce error.

The manufacturer's user's manual will be reviewed and referenced to address technical difficulties and/or malfunctions with the unit.

5. Quality Control

The DGPS has quality control features within the system that maintain reliable readings. The DGPS will indicate the number of satellites available, the strength of each satellite signal, and will not display coordinates for a given location if there is not a sufficient number of satellites available to take an accurate measurement. The DGPS will also make sure that the satellite geometry is able to account for the three-dimensional position. The DGPS averages data from satellites over time; therefore, waiting at least 1 minute before recording coordinates at each sampling location will provide a more accurate reading.

To confirm the accuracy of the DGPS unit, a checkpoint (e.g. temporary benchmark) will be located at a known point, such as a pier face, dock, piling, or similar structure that is accessible by the sampling vessel. At the beginning and end of each day, the vessel will be stationed at the checkpoint, the external DGPS antenna will be placed directly above the established checkpoint, a DGPS position reading will be taken, and the reading will be compared with the coordinates of the known point. The two position readings should agree to within 1 foot.

No. 2**

Positioning

August 2015

Revision 0

1. Purpose and Scope	3
2. Procedures	3
2.1 Equipment List	3
2.2 Positioning Vessel	4
2.2.1 Establishing Position at a Location	5
2.2.2 Adjusting Position	6
2.3 Calibration, Maintenance, and Use of Field Instruments	6
3. Quality Assurance	7
4. Documentation	7
5. References	7

1. Purpose and Scope

The purpose of this document is to define the standard operating procedure (SOP) for positioning vessels for the Newark Bay Study Area Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP). Positioning will be conducted to locate the vessel(s) and sample locations with sufficient accuracy and precision to meet project objectives during sampling activities.

This SOP describes the equipment, field procedures, materials, and documentation procedures necessary to position vessels and locate sampling locations. Specific information regarding proposed sampling locations is provided in the SQT QAPP.

This SOP may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s (Tierra's) Facility Coordinator and the U.S. Environmental Protection Agency's Remedial Project Manager. The ultimate procedure employed will be documented in the field notebook.

Other SOPs will be utilized with this procedure, including:

- SOP No. 1 – Locating Sample Points Using Global Positioning System
- SOP No. 8 – Documenting Field Activities.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Procedures

Sampling activities will be conducted from a vessel or on land, depending on tidal stage and water depth. In accordance with the procedures outlined below, the vessels must be properly positioned and their position recorded before each activity can begin.

2.1 Equipment List

The following equipment list contains materials that may be needed in carrying out the procedures contained in this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment may be required, pending field conditions.

- personal protective equipment and other safety equipment, as required by the Health and Safety/Contingency Plan, Rev. 1 (Tierra 2007)

- vessel(s) adequate for Newark Bay conditions
- 25-watt marine VHF radio
- navigation charts and sample location figure
- differential global positioning system (DGPS) receivers, with an accuracy of ± 1 foot
- DGPS external antennas (x2)
- equipment user's manuals
- table of target sampling location coordinates
- assorted nautical equipment (e.g., anchors, lines, personal flotation devices)
- field notebook
- sample collection forms
- permanent marker or grease pencil.

2.2 Positioning Vessel

This section gives the step-by-step procedures for vessel positioning. Observations made during vessel positioning should be recorded in the field notebook, as appropriate.

A DGPS will be used to establish locations during implementation of activities specified in the SQT QAPP. One handheld DGPS unit will be on board the vessel. Its receiving antenna will be aligned with the sediment sample to be collected.

While this SOP provides general guidance and procedural steps, personnel performing positioning activities should also follow the appropriate sections of the equipment user's manuals and have the manuals available for reference at all times.

The following procedures describe the steps to establish position at a location, as well as the steps to adjust the positioning for collection of additional samples.

2.2.1 Establishing Position at a Location

Preliminary Activities

1. Obtain the appropriate sample collection form(s). Complete the Daily Activity Log provided in SOP No. 8 – Documenting Field Activities.
2. Obtain the target sampling locations. For Phase III activities, these locations will have been selected prior to commencement of field activities, as described in the SQT QAPP. The location of each target sampling location will be established in the New Jersey State Plane Coordinate System with respect to North American Datum of 1983.
3. Enter coordinates for the locations into the DGPS unit that will be on board the vessel as a waypoint.

Field Activities

1. The operation and horizontal accuracy of the handheld DGPS will be verified at the shore-based marker by recording observed horizontal (XY) data and comparing these data to the published XY data for that point. A temporary benchmark may be established at a location convenient to the vessel to facilitate daily DGPS system performance verification. DGPS system performance verification will be conducted twice per day and documented in the field notebook and data logger. The horizontal accuracy will be compared to shore-based markers to verify performance. If the verification readings are more than 1 ft different than the shore-based marker or temporary benchmark, the backup DGPS and/or antenna will be used.
2. Verify receiving antenna is properly aligned with the sampling device.
3. Identify and approach actual sampling locations by using data from the DGPS unit in the navigation mode. The navigation mode provides information on heading, distance remaining, and time remaining. This information is based on the selected waypoint location and the present location of the vessel.
4. Anchor the vessel adjacent at the planned location, if desired.
5. Once the vessel is on location, note the coordinates from the DGPS unit and check the coordinates to verify that the vessel is within the pre-determined range of the target location. For the initial attempt, confirm that the coordinates are within 5 feet of the target. For subsequent attempts, see Section 2.2.2 below. If not

acceptable, adjust the vessel's location and recheck the position. Repeat this process until the vessel's position is within acceptable range of the target. Record the final coordinates on the appropriate form.

6. Once the coordinates are acceptable, perform sampling activity at the location. Record final location coordinates on the appropriate form. Plot locations onto a master chart or use computer-based, real-time software to verify location.
7. At the end of the sampling day, check the data loaded onto the DGPS units to verify the existence of locations where data were collected.

2.2.2 Adjusting Position

The following steps will be used to adjust position for sampling activities:

1. Move vessel 10 feet from the initial sampling location and within a 50-foot radius of the target coordinates.
2. Check the coordinates to verify that the vessel is within 50 feet of the target coordinate and note coordinates on the Collection Form.
3. Once the coordinates are acceptable and recorded, collect samples. Record the final location.
4. Repeat Steps 1 through 3 until the appropriate number of samples is collected.

2.3 Calibration, Maintenance, and Use of Field Instruments

Prior to use, the DGPS units will be inspected in accordance with the SQT QAPP. The performance of the DGPS units will be verified in accordance with the SQT QAPP, appropriate sections of the equipment user's manual, and as described in Section 2.2 of this SOP. Maintenance and use of DGPS units should follow the appropriate sections of the equipment user's manual. Field personnel will have the manual available for reference. Equipment inspection and maintenance will be recorded in the equipment maintenance log

Despite virtually worldwide, 24-hour coverage, technical difficulties with global positioning system (GPS) satellites can still occur. In the event of system-wide or other long-term problems with GPS (e.g., satellite failures), vessel positioning will be achieved using land-based methods. If a land-based method is selected, an SOP will be developed for its use.

3. Quality Assurance

For the Phase III Program, quality assurance (QA) activities for positioning procedures include verification of the sampling location by comparing the target coordinates specified in the SQT QAPP with coordinates entered into the DGPS, by plotting the coordinates on a master chart, and by performing the twice daily verification checks with the shore-based marker or temporary benchmark.

4. Documentation

Detailed positioning data will be recorded on the Sample Collection Forms provided in SOP No. 8 – Documenting Field Activities. In addition, the following information will be recorded in a field notebook (at a minimum):

- notes on breaking position during sampling
- equipment calibration information
- summary of vessel activities.

2.3 Field Instruments and Equipment	7
2.4 Other Equipment Decontamination	8
2.5 Equipment Leaving Newark Bay	8
2.6 Collection of Field Blank	8
3. Quality Assurance	9
4. Documentation	9
5. References	10

1. Purpose and Scope

The purpose of this document is to define the standard operating procedure (SOP) for decontamination of equipment, instruments, and other materials used during implementation of the Newark Bay Study Area Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP). Decontamination is the process of neutralizing, washing, and rinsing exposed surfaces of equipment to minimize the potential for contaminant migration and/or cross-contamination. This procedure does not apply to personnel decontamination, which is described in the Health and Safety/Contingency Plan (HASCP), Rev. 1 (Tierra Solutions, Inc. [Tierra] 2007).

This SOP may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra's Facility Coordinator and the U.S. Environmental Protection Agency's (USEPA's) Remedial Project Manager. The ultimate procedure employed will be documented in the field notebook.

Other SOPs will be utilized with this procedure, including:

- SOP No. 4 – Management and Disposal of Residuals
- SOP No. 5 – Containers, Preservation, Handling, and Tracking of Samples for Analysis
- SOP No. 6 – Sediment Sample Collection
- SOP No. 8 – Documenting Field Activities.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Procedures

2.1 Equipment List

The following equipment list contains materials that may be needed in carrying out the procedures contained in this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment may be required, pending field conditions.

- personal protective equipment (PPE) and other safety equipment, as required by the Phase II RIWP HASCP, Rev. 1 (Tierra 2007)

- bristle brushes
- wash/rinse containers (e.g., tubs, buckets)
- low-phosphate detergent
- 10% nitric acid, ultrapure
- acetone, methanol, and hexane (pesticide grade or better in separate Teflon[®] bottles), as necessary
- deionized "analyte-free" water
- stainless steel bowls
- aluminum foil
- tap water (from any treated municipal water supply)
- high-pressure/steam cleaner
- sample container(s) for rinsate blank, if collected
- field notebook.

2.2 Sample Equipment and Decontamination

Sampling equipment (including newly purchased equipment) that comes into contact with the media to be sampled will be decontaminated prior to use in the field to eliminate or minimize cross-contamination. The frequency of decontamination is provided in SOP No. 6 – Sediment Sample Collection. Sufficient decontaminated equipment must be available to be dedicated to the sampling locations planned for each day. Equipment will be decontaminated in the area designated for decontamination.

The decontamination procedure followed by USEPA Region 2 (USEPA 1989) – with the exception of the second tap water rinse being replaced with a deionized “analyte-free” water rinse – will be used prior to each sampling event for equipment that will come into contact with the media to be sampled. USEPA Region 2 procedures are summarized below:

1. Wash and scrub with low-phosphate detergent.

2. Rinse with tap water.
3. Rinse with 10% nitric acid, ultrapure.
4. Rinse with deionized "analyte-free" water.
5. Spray or rinse with acetone only or a methanol rinse followed by hexane spray or rinse (solvents must be pesticide grade or better)¹.
6. Rinse thoroughly with deionized ("analyte-free") water.
7. Air dry.
8. Wrap in aluminum foil, shiny side out, for temporary storage and transport.

Sampling equipment will be decontaminated as described in Section 2.2.1 below. Decontamination of the sampling equipment will be sufficient for collecting samples for the analysis of dioxin/furan congeners and homologues (PCDDs/PCDFs), including all other analytes, and will consist of a methanol rinse followed by a hexane rinse as described in Section 2.2.1.

Solvents used during decontamination activities will be collected and handled in accordance with residuals management procedures outlined in SOP No. 4 – Management and Disposal of Residuals.

Not all sampling equipment will require the full decontamination procedures listed in the USEPA Region 2 Comprehensive Environmental Response, Compensation, and Liability Act Quality Assurance Manual. Three levels of decontamination (i.e., solvent, soap and water, or ambient [Newark Bay] water decontamination) will be performed based on the usage of the sampling equipment as defined below.

2.2.1 Decontamination with Solvents

The following steps will be used to decontaminate sampling equipment that will come into contact with sediment designated for chemical analysis (i.e., stainless steel trowels, spoons and bowls, sediment sampling device):

¹ The methanol plus hexane method is required for pending analyses of dioxin/furan congeners and homologues (PCDDs/PCDFs). Therefore, for sampling activities in Newark Bay, this will be the approach used for decontamination of sampling equipment (See section 2.2.1).

- Personnel will dress in suitable PPE to reduce exposure to chemicals and contaminants as discussed in the Phase II RIWP HASCP, Rev. 1 (Tierra 2007).
- Residual sample media at the coring location (i.e., on the vessel) will be scraped off and the equipment rinsed with Newark Bay water.
- Rinse water will not be contained.
- Residual sample media on equipment at the sample processing site will be scraped off and collected according to residuals management procedures outlined in SOP No. 4 – Management and Disposal of Residuals.
- Equipment will be placed in a wash tub or bucket containing Alconox (or other low-phosphate detergent) along with tap water, and scrubbed with a bristle brush or similar utensil. Equipment will be rinsed with tap water in a second wash tub or bucket, followed by a nitric acid rinse (for metals analyses), a deionized “analyte-free” water rinse, a methanol rinse followed by a hexane rinse (for organic analyses), and lastly with a deionized water rinse. Rinses will utilize sufficient amounts of solvent/water to flush rather than just wet the surface. The volume of deionized water used during the rinse must be at least five times the volume of solvent used.
- Following decontamination, equipment will be placed in a clean area and allowed to air dry. Following air drying, the equipment will be wrapped in aluminum foil, shiny side out, until used for sample collection.
- Used decontamination water will be collected and handled in accordance with residuals management procedures outlined in SOP No. 4 – Management and Disposal of Residuals.

2.2.2 Decontamination with Soap and Water

The following steps will be used to decontaminate equipment not intended to collect samples for chemical analysis:

- Personnel will dress in suitable PPE to reduce exposure to contaminants as discussed in the Phase II RIWP HASCP, Rev. 1 (Tierra 2007).
- Residual sample media at the sample location (i.e., on the vessel) will be scraped off and the equipment rinsed with Newark Bay water.
- Rinse water will not be contained.

- Residual sample media on equipment at the sample processing site will be scraped off and collected according to residuals management procedures outlined in SOP No. 4 – Management and Disposal of Residuals.
- Equipment will be placed in a wash tub or bucket containing Alconox (or other low-phosphate detergent) and tap water, and scrubbed with a bristle brush or similar utensil. Equipment will be rinsed with tap water in a second wash tub or bucket, and then rinsed again.
- Following decontamination, equipment will be placed in a dedicated clean area.
- Rinse water and detergent water will be replaced frequently. Used decontamination water will be collected and handled in accordance with residuals management procedures outlined in SOP No. 4 – Management and Disposal of Residuals.

2.2.3 Decontamination with Ambient (Newark Bay) Water

The following steps will be used to decontaminate sampling and support vessels, vessel anchors, lines, ropes, submersible pump and hose (not intended for sample collection), and buoy marker weights:

- Personnel will dress in suitable PPE to reduce exposure to contaminants (Phase II RIWP HASCP, Rev. 1 [Tierra 2007]).
- Equipment will be rinsed with Newark Bay water onboard the sampling vessel.
- Rinse water will not be contained.

Daily decontamination of the decks of the vessels will consist of Newark Bay water washing as soon as possible after concluding work. Further wash-down with tap water at the marina is at the discretion of the boat's captain.

2.3 Field Instruments and Equipment

Instrumentation should be cleaned according to the manufacturer's instructions. Care will be taken to prevent damage to equipment. When possible, instruments difficult to decontaminate, such as cameras and data logging instruments, may be protectively wrapped to reduce or eliminate the need for decontamination.

2.4 Other Equipment Decontamination

Other sampling equipment that might be used that has had direct contact with sediments or wastes will be decontaminated at a designated area prior to leaving the site. The decontamination procedure will be as follows:

- Equipment will be wrapped or draped in plastic or placed in the plastic-lined cargo area of a truck for transport to the area designated for decontamination.
- Equipment will first be washed with a hot water, high-pressure spray or steam-cleaned.
- Equipment will then be rinsed, by hose or high pressure spray, with tap water.
- Wash and rinse water will be collected and handled in accordance with residuals management procedures outlined in SOP No. 4 – Management and Disposal of Residuals.

2.5 Equipment Leaving Newark Bay

Equipment leaving the site upon the completion of on-site investigation activities will be decontaminated according to Sections 2.2, 2.3, or 2.4.

2.6 Collection of Field Blank

Field blanks will be collected to assess the adequacy of equipment decontamination procedures. Field blanks are submitted for testing each day a decontamination event is carried out (not to exceed one per day). Following sample collection and processing, all pieces of equipment (both used and unused) belonging to the equipment set will be decontaminated during the decontamination event. One set of equipment will be used throughout the sample collection and processing activities to confirm the field blank corresponds to one set of samples (e.g., a given stainless steel bowl and spoon will be considered a set and will be used together throughout the sample processing activities).

The field blank collection procedures for all analytes, except dioxin/furan analysis, are as follows:

- Pour analyte-free water over a representative set of sampling equipment (e.g., stainless steel bowl, stainless steel pan) after it has been decontaminated.

- Collect rinsate in a previously decontaminated stainless steel bowl and transfer rinsate to sample bottles for analysis.
- Preserve rinsate sample, as necessary, in accordance with SOP No. 5 – Containers, Preservatives, Handling, and Tracking of Samples for Analysis.

For the purposes of the Phase III Program, field blank samples for dioxin/furan analysis will be collected using hexane, rather than spectrophotometric-grade trichloroethene (TCE) specified by USEPA Region 2 (USEPA 1989). Because TCE is a potential target analyte for this Remedial Investigation Program, hexane was substituted to eliminate the potential for obtaining erroneous positive TCE results in collected field samples. Field blank collection procedures for dioxin/furan analysis will be as follows:

- Following collection of the field blank samples for all other analytes, pour hexane over a representative set of sampling equipment (e.g., stainless steel bowl, stainless steel pan) after it has been decontaminated.
- Collect rinsate in a previously decontaminated stainless steel bowl and transfer rinsate to sample bottles for analysis.
- Preserve rinsate sample, as necessary, in accordance with SOP No. 5 – Containers, Preservatives, Handling, and Tracking of Samples for Analysis.

3. Quality Assurance

Decontamination quality assurance/quality control procedures described in Section 2.6 will be performed to assess the adequacy of equipment decontamination procedures. Field blanks will be collected at the frequency specified in Worksheet No. 28 of the SQT QAPP.

4. Documentation

Field personnel are responsible for documenting decontamination activities related to their on-site activities in accordance with SOP No. 8 – Documenting Field Activities. In addition to this, the following information should also be included in the field notebook (at a minimum):

- Information concerning items decontaminated and the procedure utilized.
- Information related to the collection of field blank samples.

1. Purpose and Scope

The purpose of this document is to define the standard operating procedure (SOP) for disposal of sediment, water, personal protective equipment (PPE), and other potentially contaminated materials generated during Newark Bay Study Area Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP) operations.

This SOP provides procedures for handling potentially contaminated sediment, water, PPE, and other materials during coring and sampling activities through their ultimate disposal. Specific information regarding handling and disposal of residuals is provided in the SQT QAPP.

This SOP may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modifications to this SOP will be approved in advance by Tierra Solutions Inc.'s (Tierra's) Facility Coordinator and the U.S. Environmental Protection Agency's (USEPA's) Remedial Project Manager. The ultimate procedure employed will be documented in the field notebook.

Other SOPs will be utilized in conjunction with this SOP, including:

- SOP No. 3 – Decontamination
- SOP No. 8 – Documenting Field Activities.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Procedures

Potentially contaminated sediment, water, PPE, and other materials will be classified into three categories:

- 1) solid materials consisting of sediments, sediment samples returned from the laboratory, used PPE, and other materials used in the handling, processing, and storage of sediment (addressed in Section 2.2);
- 2) liquid wastes, such as wastewater, decontamination water, and aqueous samples returned from the laboratory (addressed in Section 2.3); and
- 3) spent and residual chemicals (liquids) from decontamination (addressed in Section 2.3).

Sediment from samples not processed for chemical analysis may be either archived or disposed, and will be segregated and handled separately according to its classification. To the extent practical, liquids generated during sampling/decontamination operations should be separated from the solid material. Each type of material should be handled in the manner described in this SOP.

2.1 Equipment List

The following equipment list contains materials that may be needed to carry out the procedures contained in this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment may be required, pending field conditions.

- PPE or other safety equipment, as required by the Phase II RIWP Health and Safety/Contingency Plan, Rev. 1 (Tierra 2007)
- 55-gallon open-top drums (Department of Transportation- [DOT-] approved) with lid
- 30-gallon (minimum) garbage bags
- permanent marking pens and/or paint pens
- labels
- duct tape
- storage racks
- chemical storage cabinet (meeting Occupational Safety and Health Administration and National Fire Protection Association Code 30 specifications/Factory Manual approved)
- field notebook

2.2 Solid Materials

2.2.1 Solid Residuals for Disposal

Solid residuals generated during field activities will be characterized for appropriate off-site disposal. Characterization procedures will be completed in accordance with the Waste Characterization QAPP (Tierra 2011). Solid residuals consist of two types of materials: non-sediment solid materials generated during the collection and processing

of sediment samples (e.g., used core tubes, aluminum foil, PPE [e.g., gloves, Tyvek® suits, boot covers]) and sediment solid materials (i.e., left-over sediment not used for analyses, including waste sediment and residual sediment). Non-sediment and sediment wastes will be segregated and temporarily stored in separate containers pending disposal. Loose sediment will be removed from non-sediment waste items prior to disposal and stored with sediment waste.

If recovered sediment is determined to be unusable, the sediment will be stored in an appropriate container for disposal as sediment waste. Sediment solid material will be placed in 55-gallon drums, labeled, and stored temporarily until disposal.

Non-sediment solid materials will be placed in 55-gallon drums, bulk bags, and/or a roll-off container and stored temporarily pending characterization and off-site disposal in accordance with the Investigation Work Plan Sediment Investigation Program Investigation Derived Waste Management Plan (IDW Management Plan; Tierra 2006) (including any subsequent USEPA-approved modifications). All drums and bags containing solids residuals will be labeled and handled as described in Section 2.4 of this SOP.

2.3 Liquid Wastes

2.3.1 Wastewater

Wastewater will be generated during sample collection and decontamination activities. Water mixed with detergent or chemicals will be treated and handled at the Lister Avenue groundwater treatment plant. Water from gross decontamination (e.g., to wash sediment from sampling equipment) will be allowed to flow overboard on the vessel when decontamination activities occur over water. If decontamination activities occur in an upland area, the water will be captured and treated at the Lister Avenue groundwater treatment plant. Sediment recovered during this process will be handled according to Section 2.2.1 of this SOP.

In the event that wastewater is not treated through the Lister Avenue groundwater treatment plant, it will be stored at the Lister Avenue Site in appropriate containers pending characterization for off-site disposal. Modifications to the IDW Management Plan (Tierra 2006) will be submitted to the USEPA for review and approval for characterization and off-site disposal.

2.3.2 Chemical Liquid Wastes

Spent solvents, acids, and other residual chemicals generated during the decontamination process (SOP No. 3 – Decontamination) will be collected and treated

through the Lister Avenue groundwater treatment plant in accordance with procedures outlined in the IDW Management Plan (Tierra 2006).

In the event that these liquids are not treated through the Lister Avenue groundwater treatment plant, they will be stored at the Lister Avenue site in appropriate containers pending characterization for off-site disposal. Modifications to the IDW Management Plan (Tierra 2006) will be submitted to the USEPA for review and approval for characterization and off-site disposal.

2.4 Handling and Tracking of Solid Materials and Containers

As waste sediment and other solid waste materials are generated during field activities, they will be placed in DOT-approved 55-gallon drums or 30-gallon bags. Solid waste materials initially placed in bags may be bulked into 55-gallon drums for storage. The following procedures will be followed for storing sediment and other solid waste in these drums:

- A drum number will be assigned to each drum by the Field Supervisor or their designee. The drum number will be clearly marked on multiple places on the drum.
- A log will be kept for each drum, listing the materials placed in that drum. All solid materials will be segregated based on the type of material (e.g., sediment, coring tubes, PPE, waste plastic, paper, foil) and, to the extent practicable, by where they were generated (e.g., location within Newark Bay).
- Drums will be closed or covered at the end of the day's work.
- Collection drums may be reused at the processing facility after emptying.
- Drums containing solid materials will be stored in a secured temporary facility until proper off-site disposal can be coordinated.

2.5 Handling and Tracking of Wastewater and Chemical Liquid Wastes and Containers

As wastewater and chemical liquid wastes are generated during field activities, they will be treated directly through the on-site Lister Avenue groundwater treatment plant and/or will be placed in separate DOT-approved 55-gallon drums. The following procedures will be followed for treating the liquids through the on-site groundwater treatment plant:

- A sump will be isolated in the processing area to collect and handle liquids.

- Liquids collected in the sump will be combined and treated with the liquids treated at the on-site groundwater treatment plant.
- Treated liquids will be monitored, characterized, and disposed in accordance with the requirements for the on-site groundwater treatment plant.

The following procedures will be followed for storing wastewater and chemical liquid wastes in drums:

- A separate drum will be used for each non-commingled chemical. Another, separate drum will be used for chemicals and/or water that have been mixed.
- A drum number will be assigned to each drum by the Field Supervisor or their designee. The drum number will be clearly marked on multiple places on the drum.
- A log will be kept for each drum, listing the materials placed in that drum.
- All drums will be closed or covered at the end of the day's work.
- Collection drums may be reused at the sample processing area after emptying.
- Drums containing wastewater and chemical liquid wastes will be stored in a secured temporary facility until proper off-site disposal can be coordinated upon the completion of the sampling event.

2.6 Samples Returned from Off-Site Laboratories

Upon completion of the required chemical analyses, remaining sample material and sample containers from the laboratory will be returned to the sample processing area. Returned sample material/containers will be transported under chain of custody procedures, and remain in custody until disposal. Upon receipt, the chain of custody form will be signed and the samples will be logged in by a project staff member. The approximate volume of sample material and the condition of the containers in which the samples are returned will be checked and recorded in a field notebook.

Samples will be separated into sediment and aqueous sample groups; empty sample containers will be grouped accordingly by sample matrix. Sediment samples will be placed in a DOT-approved 55-gallon drum and characterized and disposed off-site in accordance with the procedures outlined in the IDW Management Plan (Tierra 2006) (including any subsequent USEPA-approved modifications).

Aqueous samples returned from the analytical laboratories will be treated through the Lister Avenue groundwater treatment plan in accordance with procedures outlined in the IDW Management Plan (Tierra 2006) (including any subsequent USEPA-approved modifications). In the event that these liquids are not treated through the Lister Avenue groundwater treatment plant, they will be stored at the Lister Avenue site in appropriate containers pending characterization for off-site disposal. Modifications to the IDW Management Plan will be submitted to USEPA for review and approval for characterization and off-site disposal.

3. Quality Assurance

Disposal procedures will be documented in a field notebook to confirm that disposal activities are conducted in accordance with the procedures outlined in the SOPs. Waste manifests will be obtained for solid and aqueous waste disposal to verify that proper transportation and disposal of these materials has occurred in accordance with the IDW Management Plan (Tierra 2006) (including any subsequent USEPA-approved modifications).

4. Documentation

Documentation of sample handling activities will be conducted in accordance with SOP No. 8 – Documenting Field Activities. In addition, the following information should be included in the field notebook (at a minimum):

- name of person performing residual management or disposal activities
- date and time of activity
- information coordinating container numbers for drums or bags containing solid materials with sample numbers, core boring numbers, or origin
- information coordinating origin of waste liquid (water or chemical[s]) with specific waste drum or tank.

1. Purpose and Scope

The purpose of this document is to define the standard operating procedure (SOP) for containerizing, preserving, handling, tracking, and shipping samples collected as part of the associated Newark Bay Study Area (NBSA) Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP). Samples may include sediment collected or generated for chemical analysis, toxicity testing, benthic community analysis, bioaccumulation testing and tissue generated for chemical analysis from the bioaccumulation testing, passive sampler analysis, and associated quality assurance (QA) analysis. This SOP is intended to be complete enough so that: 1) the steps that could affect tracking, documentation, or integrity of samples are explained in sufficient detail and 2) different sampling personnel following these procedures will deliver samples to the laboratory that are equally reliable and consistent, and in compliance with regulatory agency requirements. Specific information regarding sample collection and analysis is found in the associated SQT QAPP.

This SOP may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions, Inc.'s (Tierra's) Facility Coordinator and the U.S. Environmental Protection Agency's (USEPA's) Remedial Project Manager. The ultimate procedure employed will be documented in the field notebook.

Other SOPs will be utilized with this procedure, including:

- SOP No. 4 – Management and Disposal of Residuals
- SOP No. 8 – Documenting Field Activities.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Procedures

2.1 Equipment List

The following equipment list contains materials that may be needed in carrying out the procedures contained in this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment may be required, depending on field conditions.

- personal protective equipment and other safety equipment, as required by the Health and Safety/Contingency Plan, Rev. 1 (Tierra 2007)
- inert packing material (e.g., foam peanuts, vermiculite, cardboard)
- colorimetric pH test paper
- nitric acid and pipette
- isopropyl alcohol (70% or higher)
- Teflon® tape
- sample containers as specified in the SQT QAPP
- sample labels
- shipping supplies (e.g., “Environmental Sample” stickers, “This Side Up” labels, FedEx shipping documents, and hangtags)
- chain of custody
- Sample Delivery Group (SDG) Tracking Logs
- ice chest(s)
- custody seals
- indelible marking pens
- shipping tape
- sealable plastic bags
- temperature blanks (if not provided by the laboratory)
- field notebook
- ice or similar chilling source
- potassium iodide starch paper

- spatula
- sodium hydroxide and pipette
- plastic lining material
- clear tape.

2.2 Sample Identification and Labeling

2.2.1 Sample Identification Code

The standard sample identification number will consist of a unique 14-character string used to identify each sample collected and submitted to the laboratories for analysis, as follows:

Characters 1 and 2: Two characters to describe the water body where the sample was collected (i.e., for Phase III this will be NB for Newark Bay).

Characters 3 and 4: Two digits to describe the phase during which the sample was collected. For example, the Phase III SI Program will be described as "03."

Characters 5 through 11: Three characters to describe the sample matrix. For example, this will be "SED" for sediment and "TIS" for tissue. The following additional characters will denote the type of analysis for the different sediment samples:

- SED-BIO – bioaccumulation
- SED-CHM – chemistry
- SED-COM – benthic community
- SED-TOX – toxicity
- SED-POR – porewater
- TIS-BIO – tissue from bioaccumulation testing

Characters 12, 13, and 14: A three-digit number to describe the sample collection location (sequentially numbered from 001 to 999). Note that sample numbering for the Phase III Program ended at 135. For the continuation of the Phase III Program, sediment sample locations will begin with 136.

Location Identifier

Location IDs are pre-assigned and are found in the associated SQT QAPP. The location ID and location information (coordinates) will be recorded (see SOP No. 8 – Documenting Field Activities).

Example of Sample Identification Code

The following is an example of a sediment location identification number:

NB03SED-CHM136

Explanation:

Sample collected from Newark Bay, Phase III Program, sediment matrix, chemistry sample, sample location 136

2.2.2 Sample Delivery Group Number Identification Code

The standard SDG number will consist of a unique five-character string used to identify each SDG submitted to the laboratories for analysis, as follows:

- | | |
|---------------------|---|
| Characters 1 and 2: | Two characters to describe the Site. For the Phase III Program, this will be “NB” for Newark Bay. |
| Character 3: | One digit to describe the phase during which the sample was collected. For example, the Phase III Program will be described as “3.” |
| Characters 4 and 5: | A two-digit number to describe the SDG. |

The following is an example of an SDG number:

NB303

Explanation:

The samples in this SDG were collected from Newark Bay during the Phase III Program. The SDG was the third SDG submitted to the laboratory for analysis.

2.2.3 Quality Assurance Sample Identification Code

2.2.3.1 *Field Duplicates*

Field duplicates will be labeled by a unique 12-character string, as follows:

- | | |
|--------------------------|---|
| Characters 1 and 2: | Two characters to describe the site. For the NBSA Remedial Investigation sampling activities, "NB" will be used. |
| Characters 3 and 4: | Two digits to describe the phase during which the sample was collected. For example, the Phase III Program will be described as "03." |
| Characters 5, 6, and 7: | Three characters to describe the sample matrix. For example, this will be "SED" for sediment. |
| Characters 8, 9, and 10: | Three characters to signify a field duplicate. For the Phase III Program, this will be "DUP." Duplicate samples will be identified in a field notebook and transferred to the database. |
| Characters 11 and 12: | A two-digit number (preceded by a hyphen) to describe the order in which field duplicates are collected within the project, sequentially numbered |

The following is an example of a field duplicate:

NB03SEDDUP-03

Explanation:

The sample was the third field duplicate collected for sediment during Phase III of the NBSA Remedial Investigation.

2.2.3.2 *Field Blanks*

Field blank samples will be collected from the sampling equipment at the rate of one per decontamination event, not to exceed 1 per day.

The samples will be labeled by a unique eight-character string, as follows:

- Characters 1 and 2: Two characters to describe the site. For the NBSA Remedial Investigation sampling activities, "NB" will be used.
- Character 3: One digit to describe the phase during which the sample was collected. For example, the Phase III Program will be described as "3."
- Characters 4 through 6: A three-digit number to describe the order in which field blanks are collected within the project, sequentially numbered from the beginning of Phase III.
- Characters 7 and 8: "FB" for field blank.

The following is an example of a field blank:

NB3003FB

Explanation:

This field blank was the third collected during the Phase III Program.

2.2.3.3 Rinse Blanks

Rinse blank samples will be collected from the homogenization equipment at the analytical laboratory at the rate of one per decontamination event, not to exceed 1 per day. The samples will be labeled by a unique eight-character string, as follows:

- Characters 1 and 2: Two characters to describe the site. For the NBSA Remedial Investigation sampling activities, "NB" will be used.
- Character 3: One digit to describe the phase during which the sample was collected. For example, the Phase III Program will be described as "3."
- Characters 4 through 6: A three-digit number to describe the order in which rinse blanks are collected within the project, sequentially numbered from the beginning of Phase III.

Characters 7 and 8: "RB" for rinse blank.

The following is an example of a rinse blank:

NB3003RB

Explanation:

This rinse blank was the third collected during the Phase III Program.

2.2.3.4 Trip Blanks

Trip blanks will be numbered by a unique 13-character string, as follows:

Characters 1 and 2: Two characters to signify a trip blank. For the Phase III Program, these will be "TB."

Characters 3 through 10: Eight characters to describe the date using a two-digit month, two-digit day, and four-digit year (e.g., MMDDYYYY).

Characters 11 through 13: A hyphen followed by a two-digit number to describe the order in which trip blanks were collected that day. Each cooler with samples for volatile organic compounds (VOCs), mercury or methylmercury analysis will contain a trip blank.

The first trip blank will be "01" and will increase sequentially through the day.

The following is an example of a trip blank:

TB01012015-02

Explanation:

This sample is the second trip blank collected on January 1, 2015.

2.3 Sample Containers and Preservation

2.3.1 Sample Containers

To confirm that the appropriate sample quantities are collected in certified, pre-cleaned containers, sample containers for this project will be supplied from commercial suppliers or laboratories. Sample containers will be cleaned to the quality control standard defined in USEPA Office of Solid Waste and Emergency Response (OSWER) Directive #9240.0-05A.

Certification of sample container quality per the OSWER directive will be kept in the Newark Bay project file. The SQT QAPP summarizes container types that will be provided for collected samples.

Prior to use, the sample containers will be visually inspected for cracks, chips, or other damage. Damaged sample containers will not be used and will be disposed in the proper waste receptacle.

2.3.2 Sample Preservation – Chemical Analysis

The contracted laboratory performing the analysis will provide certified, pre-cleaned containers for sediment containing a pre-determined amount of the required preservative(s) for field blanks, as appropriate. In cases where field adjustment of pH is necessary, the procedures outlined below will be followed for the appropriate analysis.

When possible, the field blank sample containers will be pre-preserved by the laboratory. The specific preservatives to be used for each chemical analysis are summarized in the SQT QAPP. Documentation of equipment and methods used in preservation and field-adjustment of pH will be maintained in a field notebook. The chemicals and amounts used will be recorded. If refrigeration is necessary, samples will be placed on ice after collection, and shipping containers will be packed with additional ice, if needed, prior to shipment via overnight carrier.

2.3.2.1 *pH for Field Blanks for Cyanide Analysis*

Aqueous field blank sample bottles for cyanide analysis will be pre-preserved with sodium hydroxide. Immediately following sample collection, the pH of the preserved sample will be determined and adjusted, if necessary, using the following procedure:

1. Close the bottle and gently invert it several times to mix the preservative with the sample.
2. Pour a small aliquot (a few drops) of the sample into a separate vial.
3. Test the aliquot in the vial with colorimetric pH paper appropriate to the pH being tested. If the pH of the sample is less than 12, increase the pH of the field blank by adding 50% sodium hydroxide. Using a pipette, add 0.2 milliliters (mL) (four to five drops) of sodium hydroxide to the sample. If the pH is greater than 12, go to Step 5.
4. Return to Step 1.
5. Close the bottle, document in the field notebook in accordance with SOP No. 8 – Documenting Field Activities, the amount of sodium hydroxide used, the steps followed, and the number of times repeated. See Section 2.4 Sample Handling and Shipping for instruction on labeling, handling, and shipping.
6. Dispose of the aliquots used for testing the pH in accordance with SOP No. 4 – Management and Disposal of Residuals. The amount, type, and procedures will be documented

2.3.2.2 *pH for Field Blanks for Metals Analysis*

Aqueous field blank sample bottles for metals analysis will be preserved with nitric acid. Immediately following sample collection, the pH of the preserved sample will be determined and adjusted, if necessary, using the following procedure:

1. Close the bottle and gently invert it several times to mix the preservative with the sample.
2. Pour a small aliquot (a few drops) of the sample into a separate vial.
3. Test the aliquot in the vial with colorimetric pH paper appropriate to the pH being tested. If the pH of the sample is greater than 2, lower the pH of the field blank by adding nitric acid. Using a pipette, add 0.2 mL (four to five drops) of nitric acid to the sample. If the pH is less than 2, go to Step 5.
4. Return to Step 1.

5. Close the bottle, document in the field notebook in accordance with SOP No. 8 – Documenting Field Activities, the amount of nitric acid used, the steps followed, and the number of times repeated. See Section 2.4 Sample Handling and Shipping for instruction on labeling, handling, and shipping.
6. Dispose of the aliquots used for testing the pH in accordance with SOP No. 4 – Management and Disposal of Residuals. The amount, type, and procedures will be documented

2.3.2.3 *pH for Field Blanks for Total Organic Carbon Analysis*

Aqueous field blank sample bottles for total organic carbon analysis will be preserved with sulfuric acid. Immediately following sample collection, the pH of the preserved sample will be determined and adjusted, if necessary, using the following procedure:

1. Close the bottle and gently invert it several times to mix the preservative with the sample.
2. Pour a small aliquot (a few drops) of the sample into a separate vial.
3. Test the aliquot in the vial with colorimetric pH paper appropriate to the pH being tested. If the pH of the sample is greater than 2, lower the pH of the field blank by adding sulfuric acid. Using a pipette, add 0.2 mL (four to five drops) of sulfuric acid to the sample. If the pH is less than 2, go to Step 5.
4. Return to Step 1.
5. Close the bottle, document in the field notebook in accordance with SOP No. 8 – Documenting Field Activities, the amount of sulfuric acid used, the steps followed, and the number of times repeated. See Section 2.4 Sample Handling and Shipping for instruction on labeling, handling, and shipping.
6. Dispose of the aliquots used for testing the pH in accordance with SOP No. 4 – Management and Disposal of Residuals. The amount, type, and procedures will be documented

2.3.2.4 *pH for Field Blanks for Total Extractable Petroleum Hydrocarbons Analysis*

Aqueous field blank sample bottles for total extractable petroleum hydrocarbons analysis will be preserved with hydrochloride. Immediately following sample collection,

the pH of the preserved sample will be determined and adjusted, if necessary, using the following procedure:

1. Close the bottle and gently invert it several times to mix the preservative with the sample.
2. Pour a small aliquot (a few drops) of the sample into a separate vial.
3. Test the aliquot in the vial with colorimetric pH paper appropriate to the pH being tested. If the pH of the sample is greater than 2, lower the pH of the field blank by adding hydrochloride. Using a pipette, add 0.2 mL (4 to 5 drops) of hydrochloride to the sample. If the pH is less than 2, go to Step 5.
4. Return to Step 1.
5. Close the bottle, document in the field notebook in accordance with SOP No. 8 – Documenting Field Activities, the amount of hydrochloride used, the steps followed, and the number of times repeated. See Section 2.4 Sample Handling and Shipping for instruction on labeling, handling, and shipping.
6. Dispose of the aliquots used for testing the pH in accordance with SOP No. 4 – Management and Disposal of Residuals. The amount, type, and procedures will be documented

2.3.2.5 *Preparation of Field Blanks for Volatile Organic Carbon Analysis*

Aqueous field blank sample bottles for VOC analysis will be pre-preserved with sufficient hydrochloride to lower the field blank below a pH of 2. Field blanks for VOC analyses will be prepared using the following procedure:

1. Slowly pour field blank into pre-prepared VOC vial until a meniscus is formed on the top of the vial.
2. Carefully cap the VOC vial and gently invert the vial to check for air bubbles.
3. Repeat process until no air bubbles are present. Dispose VOC samples with air bubbles in accordance with SOP No. 4 – Management and Disposal of Residuals.
4. Close the bottle, document in the field notebook in accordance with SOP No. 8 – Documenting Field Activities, the steps followed repeated. See Section 2.4 Sample Handling and Shipping for instruction on labeling, handling, and shipping.

2.3.2 Sample Preservation – Benthic Community Analysis

The contracted laboratory performing the analysis will provide pre-cleaned containers for benthic community analysis. After sample collection and sieving to isolate the benthic organisms, contents of the sieve will be added to a sample jar and preserved by adding isopropyl alcohol (70-90%). Sample preservation will use the following procedure:

1. Add sieved materials to sample jar.
2. Pour isopropyl alcohol into the sample jar, filling to 0.25 to 0.5-inches from the top of the jar.
3. Close the bottle, label according to Section 2.2.4 Sample Labeling, and document, in the field notebook in accordance with SOP No. 8 – Documenting Field Activities, the amount of sodium hydroxide used, the steps followed, and the number of times repeated.
4. If contents fill the jar close to the top without adding preservative, split sample into two sample jars, and follow Step 2 above.
5. Repeat this process after each sample is sieved.

2.4 Sample Labeling, Handling, and Shipping

A label will be attached to each container used for sampling. An example of a pre-printed sample label is attached to this SOP. When practical, the project number, sample matrix, laboratory designation, and sample identification code will be typed or printed onto the label before sampling. Once affixed to the sample container, the label will be protected from water and solvents with clear packing tape.

Sample packaging and shipping will be completed in accordance with applicable regulations, as described below.

2.4.1 Chemical, Sediment Toxicity, and Bioaccumulation Analysis

1. After filling a sample container, affix cap. Clean the outside of each sample container by wiping it off with a clean paper towel. Verify that residual sediment has been removed from the outside of the container and from around the cap.

2. Securely seal cap with clear tape (except samples to be analyzed for VOCs) and complete the sample label. Apply the label to the sample container and cover with clear tape.
3. Seal each sample container for chemical analysis inside a sealable plastic bag. Samples for VOC analysis will be packaged together in a sealed plastic bag. Samples for toxicity testing and bioaccumulation will not be placed in plastic bags.
4. Place samples on ice, similar chilling source, or in refrigerator immediately after collection.
5. Transfer the samples to a plastic-lined ice chest that will be used as a shipping container. Use inert packaging material (e.g., cardboard, vermiculite) to cushion the samples and minimize the potential for breakage. Seal the drains on the ice chest (if present) with shipping tape or plug the drains with silicone sealant or a similar inert substance.
6. Place a trip blank for VOCs analysis in each cooler containing sediment samples for VOCs analysis.
7. Ice chests will contain ice or similar chilling sources sufficient to maintain a temperature of 4 degrees Celsius inside the cooler during transport. Use sufficient ice to accommodate reasonable delays in shipment. A temperature blank provided by the analytical laboratory with each cooler will be included in the shipment.
8. Complete sample tracking documentation as described in Section 2.5 of this SOP, and place the documents in a sealable plastic bag inside the ice chest, taped to the inside of the lid. Prior to sealing for shipment, check the list of samples against the container contents to verify the presence of each sample listed on the chain of custody.
9. Secure chest lid with shipping tape by covering the entire seal with tape. Complete information on the custody seal and affix the custody seal over the taped seal. An example of a custody seal is attached to this SOP.
10. For ice chests containing field blanks for dioxin/furan analysis, affix flammable liquids labels to the outside of chest and carefully complete the dangerous goods declaration form, as required by the overnight carrier.
11. Transport the shipping container directly to the laboratory, the laboratory courier, or to the overnight carrier for overnight delivery. Chemical samples will be shipped

by close of the same day the sample was collected. Sediment for toxicity and bioaccumulation analysis will be refrigerated until shipped/transported to the laboratory.

2.4.2 Porewater Analysis

1. After filling a sample container, affix lid and complete the sample label. Apply the label to the sample container and cover with clear tape.
2. Clean the outside of each sample container by wiping it off with a clean paper towel. Verify that residual sediment has been removed from the outside of the container and from the area under and around the lid.
3. Place samples on ice, similar chilling source, or in refrigerator immediately after collection.
4. Transfer the samples to the transport vehicle.
5. Complete sample tracking documentation as described in Section 2.5 of this SOP, and place the documents in a sealable plastic bag inside the ice chest, taped to the inside of the lid or accompanying the sample containers if shipped by refrigerated truck. Prior to sealing for shipment, check the list of samples against the container contents to verify the presence of each sample listed on the chain of custody.
6. Transport the containers directly to the laboratory.

2.4.3 Benthic Community Analysis

1. After filling a sample container, apply Teflon[®] tape, affix cap and securely seal with clear tape. Complete the sample label, apply the label to the sample container and cover with clear tape.
2. Clean the outside of each sample container by wiping it off with a clean paper towel. Verify that residual sediment has been removed from the outside of the container.
3. Transfer the samples to a plastic-lined ice chest that will be used as a shipping container. Use inert packaging material (e.g., cardboard, vermiculite) to cushion the samples and minimize the potential for breakage. Seal the drains on the ice

chest (if present) with shipping tape or plug the drains with silicone sealant or a similar inert substance.

4. Complete sample tracking documentation as described in Section 2.5 of this SOP, and place the documents in a sealable plastic bag inside the ice chest, taped to the inside of the lid. Prior to sealing for shipment, check the list of samples against the container contents to verify the presence of each sample listed on the chain of custody.
5. Secure chest lid with shipping tape by covering the entire seal with tape. Complete information on the custody seal and affix the custody seal over the taped seal. An example of a custody seal is attached to this SOP.
6. Transport the shipping container directly to the laboratory, the laboratory courier, or to the overnight carrier for overnight delivery. Samples will be shipped by close of the same day the sample was collected.

2.5 Sample Tracking

From the time of collection through transport to final destination, the handling of samples will follow chain of custody procedures.

A sample is considered under the sampler's custody if one or more of the following criteria are met:

- sample is in the sampler's possession
- sample is in the sampler's view after being in sampler's possession
- sample was in the sampler's possession and then locked up to prevent tampering
- sample is in a designated secure area.

Samples collected for analysis will be continuously tracked in the sample processing area and while in transit to the laboratory by using the procedures below. The sample processing area will be secured (locked) with limited access.

- Individual sample containers will be properly labeled and securely sealed before being placed in the container for shipment to the laboratory.

- Pertinent information will be entered on the chain of custody form in the field (see attached chain of custody form and form key). Assignment of the SDG number, matrix spike/matrix spike duplicate (MS/MSD) assignments, and the analyses requested for each sample will be made on both the SDG Tracking Log (see attached SDG Tracking Form) and the chain of custody form.
- The chain of custody form must include the following, as required by guidance in SW-846, Test Methods for Evaluating Solid Waste (USEPA 1993): 1) project name; 2) signature of lead/responsible sampler; 3) sample number, date and time of collection, and grab or composite sample designation; 4) signatures of individuals involved in sample transfer; and 5) if applicable, the air bill or other shipping number.
- The completed chain of custody form will be signed, dated, enclosed in a sealable plastic bag with a copy of the SDG Tracking Log and placed in the container prior to shipment. A copy of both documents will be retained by field personnel and stored in a dedicated binder. Additional copies will be distributed as follows:
 - a copy will be faxed or e-mailed to the Facility Coordinator or the Facility Coordinator's designee
 - a copy will be faxed or e-mailed to the data validator
 - a copy will be faxed or e-mailed to the laboratory manager/client service representative at each laboratory being used.
- Samples will be considered in the sampler's custody while in his/her possession or within sight, or locked in a secure area prior to shipment. If the person packing the container and verifying the sample list is different from the sampler, both the sampler and the packer will sign the chain of custody form.
- Upon receipt at the laboratory, the designated laboratory sample custodian will sign the chain of custody form indicating receipt of the incoming field samples. The samples will be checked against the chain of custody form upon arrival at the laboratory. The receiving personnel will enter all arriving samples into a laboratory logbook. Any discrepancies between the samples and the chain of custody form(s), or any evidence of tampering with the shipping container or the custody seal will be immediately reported to the Facility Coordinator. The sample custodian will immediately check the temperature of the cooler upon arrival at the laboratory and record the measured temperature on the chain of custody form and in a laboratory logbook.

- A completed copy of the chain of custody form will be distributed to the following individuals on the day of sample receipt at the laboratory:
 - a copy will be faxed or e-mailed to the Facility Coordinator or the Facility Coordinator's designee
 - a copy will be faxed or e-mailed to the data validator
 - a copy will be faxed or e-mailed to the field office.

The original will be retained by the laboratory's sample custodian.

2.5.1 Bulk Sediment Shipment

Bulk sediment samples collected for analysis will be continuously tracked in the sample processing area and while in transit to the laboratory using the procedures below. The truck will be secured (locked) with limited access.

- Individual sample containers will be properly labeled and securely sealed before and during placement in the truck for shipment to the laboratory.
- Sample containers will be kept cool during transportation to the analytical laboratory, either by using coolers and ice or a refrigerated truck.
- Pertinent information will be entered on the chain of custody form in the field (see attached chain of custody form and form key). An SDG number will not be required.
- The chain of custody form must include the following, as required by guidance in SW-846, Test Methods for Evaluating Solid Waste (USEPA 1993): 1) project name; 2) signature of lead/responsible sampler; 3) sample number, date and time of collection, and grab or composite sample designation; 4) signatures of individuals involved in sample transfer.
- The completed chain of custody form will be signed, dated, and maintained with the truck driver during transportation to the analytical laboratory. A copy of the chain of custody will be retained by field personnel and stored in a dedicated binder. Additional copies will be distributed as follows:
 - a copy will be faxed or e-mailed to the Facility Coordinator or the Facility Coordinator's designee

- a copy will be faxed or e-mailed to the data validator
- a copy will be faxed or e-mailed to the laboratory manager/client service representative at each laboratory being used.
- Samples will be considered in the sampler's custody while in his/her possession including within sight, or locked in a secure area prior to shipment. If the person packing/driving the truck and verifying the sample list is different from the sampler, both the sampler and the packer/driver will sign the chain of custody form.
- During transportation to the analytical laboratory, if using ice to keep the samples cool, the driver will make frequent stops to check the status of ice and will replenish as needed prior to delivery to the analytical laboratory,
- Upon receipt at the laboratory, the designated laboratory sample custodian will sign the chain of custody form indicating receipt of the incoming field samples. The samples will be checked against the chain of custody form upon arrival at the laboratory. The receiving personnel will enter all arriving samples into a laboratory logbook. Any discrepancies between the samples and the chain of custody form(s), or any evidence of tampering with the shipping container or the custody seal will be immediately reported to the Facility Coordinator. The sample custodian will immediately check the temperature of the cooler or sample upon arrival at the laboratory and record the measured temperature on the chain of custody form and in a laboratory logbook, being careful to note what the temperature represents.
- A completed copy of the chain of custody form will be distributed to the following individuals on the day of sample receipt at the laboratory:
 - a copy will be faxed or e-mailed to the Facility Coordinator or the Facility Coordinator's designee
 - a copy will be faxed or e-mailed to the data validator
 - a copy will be faxed or e-mailed to the field office.

The original will be retained by the laboratory's sample custodian.

3. Documentation

3.1 Field Notes

Documentation of sample handling activities will be conducted in accordance with SOP No. 8 – Documenting Field Activities. The following information should also be included in the field notebook (at a minimum):

- sample IDs collected on that day
- brief synopsis of types of equipment and methods used in collecting the samples
- details regarding the field adjustment of preservatives, if necessary.

3.2 Chain of Custody Documentation

Samples will be tracked through chain of custody documentation as described in Section 2.5 of this SOP.

CHAIN OF CUSTODY FORM KEY

- (1) SDG number (as described in Section 2.2.2 of this SOP) (e.g., NB303). Leave blank for bulk sediment samples.
- (2) Page number and total number of pages for the set of chain of custody form submitted with the samples for analysis.
- (3) Analytical laboratory's internal work order number (to be completed by analytical laboratory).
- (4) Address where the analytical results are to be sent, project identifiers (location and internal project numbers), and sampler's signature.
- (5) Preservation methods and bottles.
- (6) Sample ID (e.g., NB03SED-CHM136); refer to Section 2.2.1 of this SOP for sample and QA sample IDs.
- (7) Date and time (24-hour format) of sample collection.
- (8) Check if sample was a composite sample.
- (9) Sample matrix (e.g., sediment).
- (10) Provide analysis and method for which sample is being submitted. Check the appropriate box for which analyses the sample is being submitted.
- (11) Provide any pertinent comments regarding the sample submitted for analyses (e.g., not enough sample volume for full analyses).
- (12) Provide any special instructions to the analytical laboratory.
- (13) Provide any special QA/QC instructions to the analytical laboratory.
- (14) Provide details regarding the cooler shipment (analytical laboratory name, whether the cooler was packed with ice, turnaround requirements, and shipping tracking number).
- (15) Provide details as to receipt of cooler (to be completed by analytical laboratory on receipt). Indicate if the chain of custody seal was intact and the cooler temperature upon receipt.
- (16) Signatures for custody to be completed by sampler and analytical laboratory.

SDG TRACKING LOG

SDG Number _____ (1) _____ SDG Open Date _____ (3) _____

Sample Matrix _____ (2) _____ SDG Close Date _____ (4) _____

Sample #	Sample ID	MS/MSD	Comments
1	(5)	(6)	(7)

Field Blank	(8)	N/A	(9)
Trip Blank	(10)	N/A	(11)

Notes:

1. The SDG must not exceed 20 field samples. Field blanks do not count towards the sample total. Check which of the 20 samples have been collected to include extra volume for MS/MSD and assign as such.
2. Three times the weights listed should be collected for laboratory QC (i.e., MS/MSD/internal laboratory duplicate).
3. Field duplicate is a separate sample, not to be confused with "internal lab duplicate."

SDG TRACKING LOG KEY

- (1) SDG number (as described in Section 2.2.2 of this SOP) (e.g., NB303).
- (2) Matrix of samples in this SDG (e.g., sediment).
- (3) Date first sample in SDG is collected.
- (4) Date last sample in SDG is collected.
- (5) Sample ID (e.g., NB03SED-CHM136).
- (6) Check if an MS or MSD analysis should be performed on this sample. If an MS or MSD is to be performed, note in the "Comments" column which analysis the MS/MSD should be performed for. If the sample is not to be analyzed for an MS/MSD, then leave blank.
- (7) Provide any pertinent comments regarding the samples submitted for analyses (e.g., "MS for Herbicide").
- (8) Field blank ID as described in Section 2.2.3.2 of this SOP (e.g., NB3003FB).
- (9) Provide any pertinent comments regarding the field blank submitted for analyses.
- (10) Trip blank ID as described in Section 2.2.3.4 of this SOP (e.g., TB01012015-02).
- (11) Provide any pertinent comments regarding the trip blank submitted for analysis.

Custody Seal

<p>SEALED BY</p> <p>(1)</p> <hr/>
<p>DATE (2) TIME (3)</p>

Key:

- (1) Name of individual sealing ice chest.
- (2) Date ice chest is sealed.
- (3) Time ice chest is sealed (24-hour format).

Sediment Sample Collection

August 2015

Revision 0

1. Scope and Application	3
2. Procedure	3
2.1. Equipment List	3
2.2. Sediment Sampling	5
3. Waste Management	8
4. Quality Assurance	8
5. Documentation	8
6. References	8

1. Scope and Application

This standard operating procedure (SOP) describes the collection and field screening, logging, and subsequent sampling of sediment. This SOP is based on and is in general accordance with the methods used on the Lower Passaic River Restoration Project Cooperating Parties Group Quality Assurance Project Plan, Surface Sediment Chemical Analyses and Benthic Invertebrate Toxicity and Bioaccumulation Testing (Windward 2009). The general procedures to be utilized in obtaining sediment samples are outlined below. This SOP should be followed for any collecting, processing, logging, and sampling of sediment.

This SOP may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s (Tierra's) Facility Coordinator and the U.S. Environmental Protection Agency's Remedial Project Manager. The ultimate procedure employed will be documented in field notebook.

Other SOPs will be utilized with this procedure, including:

- SOP No. 1 – Locating Sample Points Using Global Positioning System
- SOP No. 2 – Positioning
- SOP No. 3 – Decontamination
- SOP No. 4 – Management and Disposal of Residuals
- SOP No. 5 – Containers, Preservation, Handling, and Tracking of Samples for Analysis
- SOP No. 7 – Measuring Surface Water Quality
- SOP No. 8 – Documenting Field Activities.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Procedure

2.1. Equipment List

The following equipment will be needed during sediment sampling activities:

- personal protective equipment and other safety equipment, as required by the Health and Safety/Contingency Plan, Rev. 1 (HASCP; Tierra 2007)
- sampling vessel adequate for Newark Bay conditions
- marine VHF radio
- assorted nautical equipment (e.g., anchors, lines, personal flotation devices)
- deployment equipment (e.g., winches, generator)
- grab sampler (e.g., Van Veen or equivalent)
- stainless steel bowl/buckets
- 10-20-gallon stainless steel bucket/tub
- stainless steel spoons/spatulas
- mechanical mixer (e.g., portable drill fitted with stainless steel paddle, portable stainless steel cement mixer)
- duct and packing tape
- 1-quart and 1-gallon freezer bags
- tape measure
- fathometer
- global positioning system (GPS)
- Standard No. 30 (600 micron) sieve/sieve bucket
- trowel
- forceps and magnifying glass
- garbage bags
- photoionization detector (PID)
- transport container with ice

- appropriate sample containers, preservative (70-90%)
- labels, and forms
- field notebook
- erasable whiteboard
- permanent waterproof marker or grease pencil
- digital camera.

2.2 Sediment Sampling

1. Don personal protective equipment, as required by the HASCP (Tierra 2007).
2. Navigate to the sampling location in accordance with SOP No 1. – Locating Sample Points Using a Global Positioning System and SOP No. 2 – Positioning.
3. Record water quality readings in accordance with SOP No. 7 – Measuring Surface Water Quality.
4. Collect sediment using grab sampler.
 - a. Verify the sampler has been decontaminated in accordance SOP No. 3 – Decontamination.
 - b. Secure the grab sampler to a cable of adequate length connected to a winch. In some cases, the grab sampler may be deployed and retrieved manually. Set the device to close upon contact with sediment surface.
 - c. Slowly lower the grab sampler into its deployment orientation, just above the water surface. If manually deployed, lower the open sampler from the side of the boat making sure that the end of the rope is secured.
 - d. Obtain water depth (to nearest 0.1 foot) from the fathometer and record on the Grab Sample Collection Form.
 - e. Slowly lower the grab sampler into the water to the sediment surface using the water depth reading to anticipate when the bottom will be encountered. Allow the device to penetrate the sediment and close, capturing the grab sample.
 - f. Record sample location with the GPS.

- g. Record the proposed sample location in the field notebook. Location, date, time of collection, and description or surrounding area, as well as a photograph, will be recorded for each sample.
 - h. Slowly raise the grab sample to the deck of the sampling vessel.
 - i. Immediately open the sampler top panels. Assess and document the acceptability of the sample:
 - i. jaws are completely closed
 - ii. sampler achieved target penetration depth and did not over penetrate
 - iii. sampler indicates no loss of surficial sediment from inside the sampler
 - j. Open the dredge to allow the sediment to empty onto an aluminum foil pan or stainless steel bowl.
 - k. Immediately collect sediment for analysis of volatile compounds (e.g., volatile organic compounds and acid volatile sulfides/simultaneously extracted metals). Collect these samples prior to collecting the second grab.
 - l. Multiple casts will be made adjacent to one another (consistent with SOP No. 2 – Positioning) and composited at each location until sufficient sample volume is obtained.
 - m. Set aside three individual replicate grabs in separate buckets/pans for benthic community processing.
 - n. Composite remaining sediment grabs for chemical, bioaccumulation, porewater, and toxicity processing into decontaminated 10-20-gallon stainless steel bucket.
5. Homogenize sediment samples for chemical, toxicity, bioaccumulation, and porewater analyses.
- a. Prior to homogenization, remove large unrepresentative materials (e.g., stones, shells, twigs).
 - b. Mix sediment in 10-20 gallon decontaminated stainless steel bucket with decontaminated mechanical mixer until textural, color, and moisture homogeneity is achieved.

6. Collect a small aliquot (approximately 1 ounce) of sediment representative of the sediment sample and place into a zip-top bag. Perform PID headspace screening to evaluate/monitor air quality encountered during sampling activities, as follows:
 - a. Allow sample to equilibrate to an ambient temperature for approximately 15 minutes.
 - b. Insert 'sniffer' of the PID into the zip-top bag and read PID until value spikes and then stabilizes.
 - c. Record the peak value displayed by the PID.
 - d. The aliquot of sediment used for headspace testing will not be sent for laboratory analysis.
7. Photo-document the sample to provide reference for post-processing questions regarding descriptions of color/staining, general texture, recovery, etc. Photos will include the sample identification, date, and time. The photo will also include a view of a ruler or tape measure for scale.
8. Describe sediment sample according to Unified Soil Classification System and document any other observations, such as, but not limited to, color, type of organic materials present, odor¹, sheen, and staining.
9. Partition aliquots of homogenized sediment for chemical, toxicity, bioaccumulation, and porewater analyses into appropriate pre-cleaned sample bottles and buckets per SOP No. 5 – Containers, Preservation, Handling, and Tracking of Samples for Analysis
 - a. During distribution, periodically mix sediment using a stainless steel spoon or spatula to minimize stratification effects due to differential settling,
10. Sediment samples for benthic community samples will be sieved to isolate the benthic organisms.
 - a. Empty contents of one replicate into a standard sieve (No. 30) and examine and characterize the substrate composition.

¹ Sediment should not be smelled intentionally, due to health and safety concerns. However, if an odor is noted during processing activities, it should be recorded.

- b. After completing the characterization, sieve sediments using bay water over side of boat to isolate material and benthic organisms larger than the sieve size.
 - c. Hand transfer the sieve contents to a sample jar and preserve in the field using 70-90% isopropyl alcohol.
11. Samples will be packaged and shipped in accordance with the shipping SOP No. 5 – Containers, Preservation, Handling, and Tracking of Samples for Analysis.

3. Waste Management

Investigative-derived waste generated during the sediment sampling activities and disposable equipment will be transported for off-site disposal in accordance with SOP No. 4 – Management and Disposal of Residuals.

4. Quality Assurance

Field documentation, data reporting requirements, sampling handling, custody requirements, packing, handling, and shipping requirements, including laboratory custody procedures, analytical methods, quality control requirements, and laboratory specific quality assurance/quality control requirements are stated in the Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP).

5. Documentation

Documentation of sample handling activities will be conducted in accordance with SOP No. 8 – Documenting Field Activities. Upon collection of sediment samples, the sediment sample should be logged in the field notebook.

Digital photographs of typical sediment types observed at the site and any unusual features should be obtained whenever possible. All photographs should include a ruler or common object for scale. Photo location, depth, and orientation must be recorded in the daily log or field notebook, and a label showing this information in the photo is useful.

4. Documentation	6
5. References	7

1. Purpose and Scope

The purpose of this document is to define the standard operation procedure (SOP) for measurement of surface water quality parameters. Surface water quality parameters (i.e., pH, temperature, conductivity, salinity, and dissolved oxygen) will be measured, in-situ, using a multi-parameter water quality meter (YSI 6000 or equivalent). This SOP describes equipment, field procedures, and quality assurance for measuring surface water quality. This SOP is based on and is in general accordance with the methods used on the Treatability Studies – Phase I Removal Action Quality Assurance Project Plan, CERCLA Non-Time Critical Removal Action, Lower Passaic River Study Area, Revision 1 (Tierra Solutions, Inc. [Tierra] 2009).

This SOP may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s (Tierra's) Facility Coordinator and the U.S. Environmental Protection Agency's Remedial Project Manager. The ultimate procedure employed will be documented in the field notebook.

Other SOPs will be utilized with this procedure, including:

- SOP No. 1 – Locating Sample Points Using a Global Positioning System
- SOP No. 2 – Positioning
- SOP No. 3 – Decontamination
- SOP No. 8 – Documenting Field Activities.

2. Procedures

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2.1 Equipment List

The following equipment list contains materials that may be needed in carrying out the procedures for this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment may be required, pending field conditions:

- personal protective equipment (PPE) and other safety equipment, as required in the Health and Safety/Contingency Plan (HASCP), Rev. 1 (Tierra 2007)
- decontamination supplies (see SOP No. 3 – Decontamination)
- vessel(s) adequate for site conditions
- navigation chart(s) for on-water activities
- fathometer
- lead line
- multi-parameter water quality meter (YSI 6000 or equivalent)
- duct tape
- servicing supplies, such as, but not limited to, o-rings, spare parts, clamps, and miscellaneous hardware
- replacement parts for water quality meter and pump
- disposable plastic beakers
- distilled water
- thermometer
- calibration solutions
- calibration logbook
- decontamination equipment (refer to SOP No. 3 – Decontamination)
- deployment equipment (e.g., winches, generator)
- field notebook.

2.2 Maintenance Procedure

The water quality meters will be maintained according to the manufacturer's instructions. Maintenance information will be recorded in the field notebook. A

replacement water quality meter will be available on site or ready for overnight shipment, as necessary.

2.3 Calibration Procedures

The water quality meter will be calibrated at the beginning and end of each day of use following the manufacturer's instructions. Calibration information will be recorded in the field notebook and a calibration log will be maintained.

2.4 Sampling Procedures

This section gives the step-by-step procedures for measuring water quality parameters. Observations made during surface-water quality parameter measurements should be recorded in the field notebook.

2.4.2 Collecting water quality data.

1. Move sample vessel to location per SOP No. 1 – Locating Sample Points Using a Global Positioning System and SOP No. 2 – Positioning, and anchor.
2. Record water depth using the fathometer or lead line. Record the time of the water depth measurement.
3. Water quality parameters will be measured throughout the water column from the water surface to 2 feet above the sediment surface. Immerse the water quality meter and allow to soak and to equilibrate for a minimum of one minute. Lower the water quality meter at a rate of 0.5 feet per second while observing and recording the data in real time. Stop lowering the water quality meter at a height of 2 feet off the bottom, taking care not to impact or disturb bottom sediments. If the water depth is less than 2 feet, carefully lower the water quality meter so the probes are as close to mid-depth as possible, record in the data-logger, and record the actions taken in the field log.
4. Retrieve the water quality meter onto the deck of the vessel.
5. Conduct other collection activities at the location.
6. Retrieve the anchor and move the vessel to the next location in accordance with SOP No. 1 – Locating Sample Points Using a Global Positioning System and SOP No. 2 – Positioning, or return to marina.

7. Prior to proceeding to the next location or returning to the marina, if there is visible sediment on the water quality meter, rinse with Newark Bay water as described in SOP No. 3 – Decontamination.

3. Quality Assurance

Entering data into the field notebook will document that the process is being followed and pertinent information is being collected and recorded in accordance with the procedures outlined in this SOP. Entries in the field notebook will be double-checked by the samplers to verify that the information is correct.

The data recorded by the water quality meter will be reviewed prior to leaving station.

Calibration standards must be stored properly according to manufacturer's instructions. Check and replace all calibration standards per manufacturer's suggestions to confirm accurate water quality meter readings.

4. Documentation

Field notes will be kept during calibration, operation, and maintenance activities, in accordance with SOP No. 8 – Documenting Field Activities. All readings taken and adjustments made during calibrations and calibration checks will be recorded in the calibration logbook, as well as with the date and time at which the procedure was completed. The serial number of the meter will be recorded and details of the calibration solutions (manufacturer, expiration date, production information, etc.) will be recorded, if available.

Field notes will be kept during surface water sampling activities in accordance with SOP No. 8 – Documenting Field Activities.

Information will be recorded in the field notebook during water quality measurements, including:

- date and time of measurements
- location of water quality meter measurements in New Jersey State Plane Coordinates (feet)
- weather condition information
- unusual conditions or problems with sampling equipment or water quality meter.

1. Purpose and Scope

The purpose of this document is to define the standard operating procedure (SOP) for the documentation of field activities associated with the Newark Bay Study Area (NBSA) Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP), including sample collection events, field measurements, and site visits. Appropriate documentation of field activities provides an accurate and comprehensive record of the work performed, sufficient for a technical peer to reconstruct the day's activities and determine that necessary requirements were met. Field records also provide evidence and support technical interpretations and judgments. The procedures and systems defined in this SOP help confirm that the records are identifiable (reference the project task/activity), retrievable, and protected from loss or damage.

NBSA field data will be recorded in field notebook entries, standardized forms, annotated maps, or photos. This SOP provides general guidance on field recordkeeping; additional details for specific procedures (e.g., chain of custody) are provided in the SOPs for individual tasks.

This SOP may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s (Tierra's) Facility Coordinator and the U.S. Environmental Protection Agency's Remedial Project Manager. The ultimate procedure employed will be documented in the field notebook.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Guidelines

The description of, and observations made, during field activities often provide the basis for technical site evaluations and other related written reports. All records and notes generated in the field will be considered controlled evidentiary documents and may be subject to scrutiny during litigation. Consequently, it is essential that the Field Supervisor or designee pay attention to detail and document to the greatest extent practicable every aspect of field activities.

Field documentation must provide sufficient information and data to enable the reconstruction of field activities. This will be achieved through the use of field forms or electronic information loggers (computer or hand-held devices).

3. Equipment and Materials

The following equipment list contains materials that may be needed in carrying out the procedures contained in this SOP. Not all equipment listed below may be necessary for a specific activity. Additional equipment may be required, pending field conditions.

- standardized field data forms (electronic and printed copies)
- site maps (electronic and printed copies)
- clipboard
- three-ring binder or equivalent
- camera
- time piece
- hand-held electronic recording device (e.g., laptop)
- field notebook
- black ballpoint pen or Sharpie® (or equivalent).

4. Procedures

4.1 General Requirements

The field records will contain sufficient detail so that the collection effort can be reconstructed without reliance on the collector's memory.

Pertinent field information will be recorded legibly in field notebook entries or an electronic log and/or in an appropriate standardized form (as described herein).

Field notebook entries will be signed and dated. No erasures or obliterations will be made. A single line (i.e., strikeout) will be drawn through incorrect entries and the corrected entry written next to the original strikeout. Strikeouts are to be initialed and dated by the originator.

The field notebook will be a bound waterproof notebook with entries made in black ballpoint pen. All notebook entries will be electronically scanned at the end of each day or as frequently as possible and saved in the project files.

Entries will be factual and observational (i.e., no speculation or opinion), and will not contain any personal information or non-project-related entries. Abbreviations and acronyms will be defined.

Field information will be recorded immediately – information recorded significantly after the fact will be dated as such.

Field activities and other events pertinent to the field activities will be documented in chronological order. Times will be recorded in local time using military format.

4.2 Field Notebook

NBSA field notebooks will be dedicated to the project and will not be used for any other project or purpose. The field notebook will be a bound waterproof notebook with entries made in black ballpoint pen. Separate and dedicated field notebooks will be kept for different operations running concurrently (e.g., sampling on board the vessel, processing at the field facility); individual tasks making up each operation will be maintained in the same field notebook, if possible. The cover and binding of each field notebook will be labeled to identify the operation and dates included with the notebook; each page in the field notebook will be consecutively numbered. Pages will not be removed or torn out of the notebook.

The first page of the field notebook will contain the following information:

- ARCADIS project manager (PM), key personnel, and their respective phone numbers
- Tierra PM, and phone number
- Emergency phone numbers
- Emergency contacts and phone numbers for personnel conducting boat work
- Marina contact, address, and phone number
- project name and number

A page header will appear on the first page of each field notebook entry (i.e., the beginning of notes for each day's events), and activities for each day will be recorded as a new logbook entry. The page header will include:

- name of author and other personnel on site (and affiliated organization if applicable)
- date
- time of arrival (military time)
- proposed activity (task)
- current weather and tidal conditions, and weather forecast for the day.

An abbreviated header, containing at least the date, will appear at the top of each additional page for the active date. Field forms require similar header information.

The field notebook will provide a chronology of events. At a minimum, documentation in a field notebook will include the following (unless documented on a standard form):

- names of visitor(s), including time of arrival and departure, the visitor's affiliation, and reason for visit
- summary of project-related communications, including names of people involved and time
- time daily work commences and ceases
- start and stop times of new tasks
- start and stop times of significant standby time (work interruptions)
- safety or other monitoring data, including units with each measurement
- deviations from approved scope of work, including the necessary approvals
- progress updates
- problems/delays encountered
- unusual events
- initials of author on every page.

The field notebook will cross-reference the standardized field forms if necessary; however, whenever possible, details recorded on the standardized forms will not be replicated in the field notebook.

In case of equipment malfunction or other unforeseen events, additional bound waterproof field notebooks will be carried by field personnel to serve as backup documentation methods. If there are additional lines on the page at the end of the day's activities, a line will be drawn through the empty space, and initialed and dated, leaving no room for additional entries. Logbook entries will be electronically scanned at the end of each day, or as frequently as possible, and electronically saved as described in Section 4.6.

4.3 Standardized Forms

The information collected on any field forms will be collected and/or scanned and stored (if a printed form) electronically (described in Section 4.6).

The following rules apply to the standardized forms:

- Each form will be printed (if electronic), signed, and dated by the person completing the form and stored as described in Section 5.
- There will be no blank spaces on the form – unused spaces will have “not applicable” or “not available” explanations.
- Field forms require similar header information as field notebook entries (see Section B of this SOP).
- At the end of each day, or as frequently as possible, all forms completed will be saved as described in Section 4.6.

4.4 Maps and Drawings

Pre-existing maps and drawings that include notations made in the field (i.e., relocating of sample locations) will be referenced in the field notebook and, like all field records, include the project/task name and number, site identification, and be signed or initialed and dated by the person who prepared them.

Maps and drawings will include compass orientation and scale. Sketches will include points of reference and distances to the reference points.

If notations are made on electronic map or drawing files, these will be referenced in the field notebook as described above and initialed and dated by the person who prepared them. Notations made by hand on maps and drawings will be electronically scanned at the end of each day, or as frequently as possible, and electronically saved as described in Section 4.6.

4.5 Photographs and Other Photo Documentation

Photographs or videos may be taken by the field team to help document site conditions, sampling locations, or sample characteristics. Photographs and videos will be identified in the field notebook or on the electronic standard form. If photographs are collected using a digital camera, camera settings should be modified to capture the current date and timestamp on the photograph. At a minimum, a log of the photograph captured, photographer's name, and camera (if more than one) will be recorded in the field notebook. Additional information may include the general location, brief description, differential global positioning system coordinates, direction the photographer was facing, and/or weather conditions. If necessary, an object will be included to indicate the scale of the object in the photograph.

Photographs will be electronically saved into a folder at the end of each day, or as frequently as possible, as described in Section 4.6.

4.6 Electronic Files

Electronic recording devices may include data logging systems, personal digital assistants (PDAs), laptops, or tablet personal computers.

Sufficient backup systems will be in place to protect against electronic data loss. Information will be saved to a disk or backed up immediately upon completion. The backup disk or other media (CD, flash drive) will then be stored in a secure location separate from the laptop, tablet, or PDA.

Files will be uniquely identified and stored in the project files. File names should include the date, a description of the file contents or a unique title, and a version number (i.e., "YYYYMMDD_Name of documentV#). An unedited version of the file will be maintained and subsequent manipulations tracked.

5. Quality Assurance/Quality Control

Entries in the field forms will be double-checked by the samplers to verify that the information is correct.

Completed field forms will be reviewed periodically by the Facility Coordinator and/or Project Quality Assurance Manager, or their designees, to verify that the requirements are being met. At a minimum, this should occur at the end of each day. When the review is complete, the reviewer will append his/her initials and date to the pages reviewed for documentation purposes.

If information recorded in the field is transcribed to another format, the original record will be retained for comparison purposes.

6. Data and Records Management

Deviations to the procedures detailed in the SOP will be recorded in the field notebook.

Notebooks, field forms, chain of custody forms, and all other records associated with the activities described in this SOP will ultimately be maintained by the investigative organization.

Field notebook entries, field data forms, and chain of custody forms will be electronically stored once they have been completed and distributed (if necessary) at the end of each field day or as frequently as possible. Printed copies of these documents will be maintained in labeled three-ring binders or contained in some other organized manner that prevents loss in the field facility. Bound waterproof field notebooks will be electronically scanned and saved in project files at the end of each day, or as frequently as possible, to mitigate against the loss of historical entries should the field notebook be lost in the field.

Distribution of daily forms will be performed according to the needs of the project team and at the direction of the Field Supervisor or designee.

The Field Supervisor is responsible for reviewing and approving the field records for accuracy, completeness, and conformance to the procedures in this SOP. The Field Supervisor is also responsible for confirming that the field records are distributed to the appropriate personnel during field activities, confirming that records are maintained properly on site, and for archiving the records upon completion of field activities.

Standard Operating Procedure No. 9

Data Review Form

1. Purpose and Scope

The purpose of this document is to define the standard operating procedure (SOP) for data management. This SOP describes the procedures necessary to manage field sampling and laboratory data. In addition to the sample collection efforts, all requirements set forth in this SOP are to apply to data collected as part of the sampling activities.

This SOP may change depending on field conditions, equipment limitations, or limitations imposed by the procedure. Substantive modification to this SOP will be approved in advance by Tierra Solutions Inc.'s (Tierra's) Facility Coordinator and the U.S. Environmental Protection Agency's (USEPA's) Remedial Project Manager. The ultimate procedure employed will be documented in the field notebook.

Other SOPs will be utilized with this procedure, including:

- SOP No. 8 – Documenting Field Activities.

In instances where this SOP will be utilized, a hard copy or electronic version will be available at the point of use.

2. Procedures

2.1 Data Handling and Management

The following sections trace the paths of data from generation to final use and storage, as well as the associated quality reviews for error detection that are performed to promote data integrity.

2.1.1 Field Data Management

2.1.1.1 *Data Recording*

Field data and information collected during sample collection may be recorded by hand using the associated forms, entering into a field notebook, or by inputting field data/information directly into an electronic field database (spreadsheet, database, or equivalent), and will be recorded in accordance with requirements described in SOP No. 8 – Documenting Field Activities.

2.1.1.2 *Data Review*

Each day after the completion of field activities, a designated team member, who will be different from the originator of the field data, will perform an on-site review of the sample collection data/information. This review will include verifying:

- sediment samples were collected at pre-identified sampling locations and that prescribed sampling procedures were followed
- data and information, as well as associated forms, were completed in their entirety for each sample
- data and information entered into the database or forms are accurate and consistent with that recorded in the field notebooks (e.g., sample ID, location, time of collection).

Once the data have been verified, the selected reviewer will sign and date hard copy forms and the field notebook. Additionally, hard copy forms and the field notebook will be electronically scanned. Electronic versions (in Portable Document Format [PDF] format, or equivalent) of all forms will be placed on a secure network drive accessible only to project personnel. The data will be sent to the ARCADIS office for review each day.

Upon receipt of daily documentation (including the electronic field database and scanned hard copy forms and field notebook), the office data manager will perform a secondary review of the daily field data for consistency and accuracy.

If an electronic field database is maintained, the office data manager will import the data sent from the site. If generated, the electronic field database will contain data collected during sample collection and sample processing activities for the entire project. The electronic field database will be placed on a secure network drive, accessible only to project personnel, for storage/filing purposes.

2.1.2 Analytical Data Management

2.1.2.1 *Data Recording*

The laboratory(ies) will prepare and retain full analytical and quality control (QC) documentation. Laboratory records (both handwritten and electronic) will be documented per the procedures contained in the laboratory-specific quality assurance (QA) manual. Once the hard copy data packages and Electronic Data Deliverables

(EDDs) are ready, they will be verified by the laboratory for completeness and compliance prior to submittal to the Quality Assurance Coordinator (QAC).

Due to the nature of the toxicity and benthic community data, EDDs will not be provided by the laboratories. Instead, data will be provided to the QAC in hard copy and electronic format via spreadsheet (or equivalent method). The spreadsheets will be verified by the laboratory for completeness and compliance prior to submittal to the QAC.

2.1.2.2 *Data Transformation and Data Reductions*

Calculations involved in reducing raw data to reportable data are defined in the specified analytical methods. Automated data processing steps not provided in the procedures listed can be found in the laboratory-specific QA manuals. Verification of records and calculations generated by the laboratories will be performed as required tasks and documented by signature of reviewer/data validation contractor.

Significant digits for hard copy and electronic results will be reported as specified in the analytical method reference.

2.1.2.3 *Data Transfer*

Unverified/unvalidated data will be transferred electronically from the identified analytical laboratories to the QAC using the EDD format (or spreadsheets, as described in Section 2.1.2.1 of this SOP), specified in Worksheet No. 29 of the Sediment Quality Triad and Porewater Sampling and Analysis Quality Assurance Project Plan (SQT QAPP). The data will be transferred in spreadsheet format (or equivalent) via e-mail or similar information transfer mechanism.

2.2 **Data Tracking and Control**

The following sections provide a discussion of the procedures for data tracking, storage, archiving, retrieval, and security for both hard copy and electronic data and information.

2.2.1 Data Storage, Archiving, and Retrieval

2.2.1.1 *Hard Copy Files*

Hard copies of project documentation and data will be placed in the project file, parts of which will exist in several locations, including:

- ARCADIS: Syracuse, New York, and Cranbury, New Jersey
- Field & Technical Services: Pittsburgh, Pennsylvania
- Tierra Solutions, Inc.: East Brunswick, New Jersey.

Such files will initially be maintained in secure locations within each facility. Hard copies of project documentation and data will be provided to USEPA upon request.

Duplicate copies of pertinent field-related correspondence/documentation will be maintained at the field office during field operations. Once such field operations have been completed, this documentation will be transferred to the project file.

Upon completion of the data verification/validation process, project documents and records will be stored in the project file. At such time that it is deemed appropriate to archive the project file, either in parts or in its entirety, files may be boxed and shipped off site to a secure document storage facility. The assigned barcode identifier for each box being archived will be logged into a tracking spreadsheet with a brief description of the contents of the box. Archived boxes will be retrieved from the document storage facility, if/when necessary, using the logged barcode identifier.

2.2.1.2 *Electronic Files*

Electronic data and information will be maintained and managed by the entities listed above using password-protected computers and on secure network drives with access limited to project personnel. Files will generally consist of the same components as the hard copy files.

Reports (including QA reports), analytical laboratory documentation, data verification reports, and field data will be in PDF format (or equivalent). Additionally, electronic copies of EDDs containing verified/validated sample results will be filed in spreadsheet format, and daily and cumulative electronic field databases will be filed in database format.

2.2.2 Data Security

Hard copy information/data will be stored in secure areas within the three project file locations. Electronic data and information will be maintained and managed using password-protected computers and on secure network drives with access limited to project personnel.

2.3 Final Data Evaluation

At her/his discretion, Tierra's Facility Coordinator may perform data evaluation activities.

3. Quality Assurance

Appropriate QA/QC procedures will be followed during data management in accordance with SOP No. 8 – Documenting Field Activities and this SOP.

4. Documentation

Field and laboratory documentation will be maintained in accordance with SOP No.8 – Documenting Field Activities and this SOP.

DATA REVIEW FORM

(Sheet 1 of 1)

Date: ____ (1) ____

SDG: ____ (2) ____

Analytical Group: _____ (3) _____

Samples Reviewed: _____ (4) _____

Identified Errors:

(5)

Corrective Actions Taken:

(6)

Person Responsible: _____ (7) _____

Attach original data table from analytical database, and final data table showing changes (if applicable) to this form for data tracking/filing purposes. Also, attach any communications (e.g., e-mails, conversation records) related to the data changes discussed above.

DATA REVIEW FORM KEY
(Sheet 1 of 1)

DESCRIPTION OF ITEMS:

- (1) Date of data review (e.g., 1/1/2015).
- (2) Sample delivery group number assigned to data package under review.
- (3) Analytical group requested for analysis under review (e.g., chlorinated herbicides).
- (4) Sample ID(s) of samples chosen for review.
- (5) Errors identified during comparison of data table from database to initialed and dated Form 1s in Data Verification Reports.
- (6) Actions taken to correct errors identified during comparison of data table from database to marked-up Form 1s in Data Verification Reports.
- (7) Name of person entering information into this form.

TPH	Total Petroleum Hydrocarbons	µg/kg	NA	NA

Ecological screening values selected, based on the following hierarchy:

1. Recommended by Partner Agencies: Ecological sediment screening levels for saline waters —as recommended by the Partner Agencies for the lower Passaic River in email correspondence to Scott Kirchner of CDM dated May 26, 2011.
2. NJDEP ESC Table - Marine: NJDEP Ecological Screening Criteria (ESC) for Marine Sediment. March 2009.
3. NJDEP ESC Table - Freshwater: NJDEP Ecological Screening Criteria (ESC) for Freshwater Sediment. March 2009.
4. USEPA Reg 3 - Marine: USEPA Region 3 Marine Sediment Screening Benchmarks. July 2006.
5. USEPA Reg 3 - Freshwater: USEPA Region 3 Freshwater Sediment Screening Benchmarks. August 2006.
6. USEPA Reg 5: USEPA Region 5 Resource Conservation and Recovery Act (RCRA) Ecological Screening Levels. August 2003.
For the individual PCBs currently lacking a screening value, a screening value of 0.000034 mg/kg will be used for sediment.
This is the lowest screening value of all individual PCBs.
7. Screening values for sediment are Residential USEPA Soil RSLs from the November 2013 version of the RSLs, set to a HQ of 0.1 and a risk level of 10-6; http://www.epa.gov/reg3hwmd/risk/human/rb-concentration_table/index.htm.

Abbreviations:

C - based on carcinogenic effects, CAS - Chemical Abstracts Service number, DL - dioxin-like, M - maximum contaminant level, mg/kg - milligram per kilogram, N - based on noncarcinogenic effects
 NA - not applicable, ND - non dioxin-like, NOAEL - no observed adverse effect level, PAH - polycyclic aromatic hydrocarbon, PBB - polybrominated biphenyl
 PCB - polychlorinated biphenyl, PCN - polychlorinated naphthalene, RSL - regional screening level, TBD - to be determined, µg/L - micrograms per liter, USEPA - U.S. Environmental Protection Agency, ww - wet weight

Notes:

The 4 essential nutrients lacking EPA RSLs will be screened from the BHHRA.
 Screening levels for chemicals lacking EPA RSLs will be determined at a later date (TBD).
 RSLs reflect residential values from the November 2013 version of the RSLs.
 For the individual PCBs currently lacking values (indicated as TBD), a screening value of 0.00158 mg/kg will be used for tissue. This is the screening value for Total PCBs.
 Human health fish tissue screening levels were calculated using the USEPA RSL online calculator, set to a HQ of 0.1 and a risk level of 10⁻⁶; accessed from http://epa-prgs.orl.gov/cgi-bin/chemicals/csl_search.

Acknowledgments

This method was prepared under the direction of William A. Telliard of the Engineering and Analysis Division within the EPA Office of Water. This document was prepared under EPA Contract No. 68-C3-0337 by DynCorp Environmental Services Division with assistance from its subcontractor Interface, Inc.

Disclaimer

This method has been reviewed by the Engineering and Analysis Division, U.S. Environmental Protection Agency, and approved for publication. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

Introduction

Method 1613 was developed by the United States Environmental Protection Agency's Office of Science and Technology for isomer-specific determination of the 2,3,7,8-substituted, tetra-through octa-chlorinated, dibenzo-*p*-dioxins and dibenzofurans in aqueous, solid, and tissue matrices by isotope dilution, high resolution capillary column gas chromatography (HRGC)/high resolution mass spectrometry (HRMS).

Questions concerning this method or its application should be addressed to:

Method 1613, Revision B
Tetra- through Octa-Chlorinated Dioxins and Furans by Isotope
Dilution HRGC/HRMS

1.0 Scope and Application

- 1.1 This method is for determination of tetra- through octa-chlorinated dibenzo-*p*-dioxins (CDDs) and dibenzofurans (CDFs) in water, soil, sediment, sludge, tissue, and other sample matrices by high resolution gas chromatography/high resolution mass spectrometry (HRGC/HRMS). The method is for use in EPA's data gathering and monitoring programs associated with the Clean Water Act, the Resource Conservation and Recovery Act, the Comprehensive Environmental Response, Compensation and Liability Act, and the Safe Drinking Water Act. The method is based on a compilation of EPA, industry, commercial laboratory, and academic methods (References 1-6).
- 1.2 The seventeen 2,3,7,8-substituted CDDs/CDFs listed in Table 1 may be determined by this method. Specifications are also provided for separate determination of 2,3,7,8-tetrachloro-dibenzo-*p*-dioxin (2,3,7,8-TCDD) and 2,3,7,8-tetrachloro-dibenzofuran (2,3,7,8-TCDF).
- 1.3 The detection limits and quantitation levels in this method are usually dependent on the level of interferences rather than instrumental limitations. The minimum levels (MLs) in Table 2 are the levels at which the CDDs/CDFs can be determined with no interferences present. The Method Detection Limit (MDL) for 2,3,7,8-TCDD has been determined as 4.4 pg/L (parts-per-quadrillion) using this method.
- 1.4 The GC/MS portions of this method are for use only by analysts experienced with HRGC/HRMS or under the close supervision of such qualified persons. Each laboratory that uses this method must demonstrate the ability to generate acceptable results using the procedure in Section 9.2.
- 1.5 This method is "performance-based". The analyst is permitted to modify the method to overcome interferences or lower the cost of measurements, provided that all performance criteria in this method are met. The requirements for establishing method equivalency are given in Section 9.1.2.
- 1.6 Any modification of this method, beyond those expressly permitted, shall be considered a major modification subject to application and approval of alternate test procedures under 40 CFR 136.4 and 136.5.

2.0 Summary of Method

Flow charts that summarize procedures for sample preparation, extraction, and analysis are given in Figure 1 for aqueous and solid samples, Figure 2 for multi-phase samples, and Figure 3 for tissue samples.

2.1 Extraction

2.1.1 Aqueous samples (samples containing less than 1% solids)—Stable isotopically labeled analogs of 15 of the 2,3,7,8-substituted CDDs/CDFs are spiked into a 1 L sample, and the sample is extracted by one of three procedures:

2.1.1.1 Samples containing no visible particles are extracted with methylene chloride in a separatory funnel or by the solid-phase extraction technique summarized in Section 2.1.1.3. The extract is concentrated for cleanup.

2.1.1.2 Samples containing visible particles are vacuum filtered through a glass-fiber filter. The filter is extracted in a Soxhlet/Dean-Stark (SDS) extractor (Reference 7), and the filtrate is extracted with methylene chloride in a separatory funnel. The methylene chloride extract is concentrated and combined with the SDS extract prior to cleanup.

2.1.1.3 The sample is vacuum filtered through a glass-fiber filter on top of a solid-phase extraction (SPE) disk. The filter and disk are extracted in an SDS extractor, and the extract is concentrated for cleanup.

2.1.2 Solid, semi-solid, and multi-phase samples (but not tissue)—The labeled compounds are spiked into a sample containing 10 g (dry weight) of solids. Samples containing multiple phases are pressure filtered and any aqueous liquid is discarded. Coarse solids are ground or homogenized. Any non-aqueous liquid from multi-phase samples is combined with the solids and extracted in an SDS extractor. The extract is concentrated for cleanup.

2.1.3 Fish and other tissue—The sample is extracted by one of two procedures:

2.1.3.1 Soxhlet or SDS extraction—A 20 g aliquot of sample is homogenized, and a 10 g aliquot is spiked with the labeled compounds. The sample is mixed with sodium sulfate, allowed to dry for 12-24 hours, and extracted for 18-24 hours using methylene chloride:hexane (1:1) in a Soxhlet extractor. The extract is evaporated to dryness, and the lipid content is determined.

2.1.3.2 HCl digestion—A 20 g aliquot is homogenized, and a 10 g aliquot is placed in a bottle and spiked with the labeled compounds. After equilibration, 200 mL of hydrochloric acid and 200 mL of methylene chloride:hexane (1:1) are added, and the bottle is agitated for 12-24 hours. The extract is evaporated to dryness, and the lipid content is determined.

2.2 After extraction, $^{37}\text{Cl}_4$ -labeled 2,3,7,8-TCDD is added to each extract to measure the efficiency of the cleanup process. Sample cleanups may include back-extraction with acid and/or base, and gel permeation, alumina, silica gel, Florisil and activated carbon chromatography. High-performance liquid chromatography (HPLC) can be used for further isolation of the 2,3,7,8-isomers or other specific isomers or congeners. Prior to the cleanup procedures cited above, tissue extracts are cleaned up using an anthropogenic isolation column, a batch silica gel adsorption, or sulfuric acid and base back-extraction, depending on the tissue extraction procedure used.

- 2.3 After cleanup, the extract is concentrated to near dryness. Immediately prior to injection, internal standards are added to each extract, and an aliquot of the extract is injected into the gas chromatograph. The analytes are separated by the GC and detected by a high-resolution ($\geq 10,000$) mass spectrometer. Two exact m/z 's are monitored for each analyte.
- 2.4 An individual CDD/CDF is identified by comparing the GC retention time and ion-abundance ratio of two exact m/z 's with the corresponding retention time of an authentic standard and the theoretical or acquired ion-abundance ratio of the two exact m/z 's. The non-2,3,7,8 substituted isomers and congeners are identified when retention times and ion-abundance ratios agree within predefined limits. Isomer specificity for 2,3,7,8-TCDD and 2,3,7,8-TCDF is achieved using GC columns that resolve these isomers from the other tetra-isomers.
- 2.5 Quantitative analysis is performed using selected ion current profile (SICP) areas, in one of three ways:
- 2.5.1 For the 15 2,3,7,8-substituted CDDs/CDFs with labeled analogs (see Table 1), the GC/MS system is calibrated, and the concentration of each compound is determined using the isotope dilution technique.
- 2.5.2 For 1,2,3,7,8,9-HxCDD, OCDF, and the labeled compounds, the GC/MS system is calibrated and the concentration of each compound is determined using the internal standard technique.
- 2.5.3 For non-2,3,7,8-substituted isomers and for all isomers at a given level of chlorination (i.e., total TCDD), concentrations are determined using response factors from calibration of the CDDs/CDFs at the same level of chlorination.
- 2.6 The quality of the analysis is assured through reproducible calibration and testing of the extraction, cleanup, and GC/MS systems.

3.0 Definitions

Definitions are given in the glossary at the end of this method.

4.0 Contamination and Interferences

- 4.1 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or elevated baselines causing misinterpretation of chromatograms (References 8-9). Specific selection of reagents and purification of solvents by distillation in all-glass systems may be required. Where possible, reagents are cleaned by extraction or solvent rinse.
- 4.2 Proper cleaning of glassware is extremely important, because glassware may not only contaminate the samples but may also remove the analytes of interest by adsorption on the glass surface.
- 4.2.1 Glassware should be rinsed with solvent and washed with a detergent solution as soon after use as is practical. Sonication of glassware containing a detergent solution for approximately 30 seconds may aid in cleaning. Glassware with

removable parts, particularly separatory funnels with fluoropolymer stopcocks, must be disassembled prior to detergent washing.

- 4.2.2 After detergent washing, glassware should be rinsed immediately, first with methanol, then with hot tap water. The tap water rinse is followed by another methanol rinse, then acetone, and then methylene chloride.
 - 4.2.3 Do not bake reusable glassware in an oven as a routine part of cleaning. Baking may be warranted after particularly dirty samples are encountered but should be minimized, as repeated baking of glassware may cause active sites on the glass surface that will irreversibly adsorb CDDs/CDFs.
 - 4.2.4 Immediately prior to use, the Soxhlet apparatus should be pre-extracted with toluene for approximately three hours (see Sections 12.3.1 through 12.3.3). Separatory funnels should be shaken with methylene chloride/toluene (80/20 mixture) for two minutes, drained, and then shaken with pure methylene chloride for two minutes.
- 4.3 All materials used in the analysis shall be demonstrated to be free from interferences by running reference matrix method blanks initially and with each sample batch (samples started through the extraction process on a given 12-hour shift, to a maximum of 20 samples).
- 4.3.1 The reference matrix must simulate, as closely as possible, the sample matrix under test. Ideally, the reference matrix should not contain the CDDs/CDFs in detectable amounts, but should contain potential interferences in the concentrations expected to be found in the samples to be analyzed. For example, a reference sample of human adipose tissue containing pentachloronaphthalene can be used to exercise the cleanup systems when samples containing pentachloronaphthalene are expected.
 - 4.3.2 When a reference matrix that simulates the sample matrix under test is not available, reagent water (Section 7.6.1) can be used to simulate water samples; playground sand (Section 7.6.2) or white quartz sand (Section 7.3.2) can be used to simulate soils; filter paper (Section 7.6.3) can be used to simulate papers and similar materials; and corn oil (Section 7.6.4) can be used to simulate tissues.
- 4.4 Interferences coextracted from samples will vary considerably from source to source, depending on the diversity of the site being sampled. Interfering compounds may be present at concentrations several orders of magnitude higher than the CDDs/CDFs. The most frequently encountered interferences are chlorinated biphenyls, methoxy biphenyls, hydroxydiphenyl ethers, benzylphenyl ethers, polynuclear aromatics, and pesticides. Because very low levels of CDDs/CDFs are measured by this method, the elimination of interferences is essential. The cleanup steps given in Section 13 can be used to reduce or eliminate these interferences and thereby permit reliable determination of the CDDs/CDFs at the levels shown in Table 2.
- 4.5 Each piece of reusable glassware should be numbered to associate that glassware with the processing of a particular sample. This will assist the laboratory in tracking possible sources of contamination for individual samples, identifying glassware associated with

highly contaminated samples that may require extra cleaning, and determining when glassware should be discarded.

- 4.6 Cleanup of tissue—The natural lipid content of tissue can interfere in the analysis of tissue samples for the CDDs/CDFs. The lipid contents of different species and portions of tissue can vary widely. Lipids are soluble to varying degrees in various organic solvents and may be present in sufficient quantity to overwhelm the column chromatographic cleanup procedures used for cleanup of sample extracts. Lipids must be removed by the lipid removal procedures in Section 13.7, followed by alumina (Section 13.4) or Florisil (Section 13.8), and carbon (Section 13.5) as minimum additional cleanup steps. If chlorodiphenyl ethers are detected, as indicated by the presence of peaks at the exact m/z 's monitored for these interferents, alumina and/or Florisil cleanup must be employed to eliminate these interferences.

5.0 Safety

- 5.1 The toxicity or carcinogenicity of each compound or reagent used in this method has not been precisely determined; however, each chemical compound should be treated as a potential health hazard. Exposure to these compounds should be reduced to the lowest possible level.
- 5.1.1 The 2,3,7,8-TCDD isomer has been found to be acnegenic, carcinogenic, and teratogenic in laboratory animal studies. It is soluble in water to approximately 200 ppt and in organic solvents to 0.14%. On the basis of the available toxicological and physical properties of 2,3,7,8-TCDD, all of the CDDs/CDFs should be handled only by highly trained personnel thoroughly familiar with handling and cautionary procedures and the associated risks.
- 5.1.2 It is recommended that the laboratory purchase dilute standard solutions of the analytes in this method. However, if primary solutions are prepared, they shall be prepared in a hood, and a NIOSH/MESA approved toxic gas respirator shall be worn when high concentrations are handled.
- 5.2 The laboratory is responsible for maintaining a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method. A reference file of material safety data sheets (MSDSs) should also be made available to all personnel involved in these analyses. It is also suggested that the laboratory perform personal hygiene monitoring of each analyst who uses this method and that the results of this monitoring be made available to the analyst. Additional information on laboratory safety can be found in References 10-13. The references and bibliography at the end of Reference 13 are particularly comprehensive in dealing with the general subject of laboratory safety.
- 5.3 The CDDs/CDFs and samples suspected to contain these compounds are handled using essentially the same techniques employed in handling radioactive or infectious materials. Well-ventilated, controlled access laboratories are required. Assistance in evaluating the health hazards of particular laboratory conditions may be obtained from certain consulting laboratories and from State Departments of Health or Labor, many of which have an industrial health service. The CDDs/CDFs are extremely toxic to laboratory animals. Each laboratory must develop a strict safety program for handling these compounds. The practices in References 2 and 14 are highly recommended.

- 5.3.1 Facility—When finely divided samples (dusts, soils, dry chemicals) are handled, all operations (including removal of samples from sample containers, weighing, transferring, and mixing) should be performed in a glove box demonstrated to be leak tight or in a fume hood demonstrated to have adequate air flow. Gross losses to the laboratory ventilation system must not be allowed. Handling of the dilute solutions normally used in analytical and animal work presents no inhalation hazards except in the case of an accident.
- 5.3.2 Protective equipment—Disposable plastic gloves, apron or lab coat, safety glasses or mask, and a glove box or fume hood adequate for radioactive work should be used. During analytical operations that may give rise to aerosols or dusts, personnel should wear respirators equipped with activated carbon filters. Eye protection equipment (preferably full face shields) must be worn while working with exposed samples or pure analytical standards. Latex gloves are commonly used to reduce exposure of the hands. When handling samples suspected or known to contain high concentrations of the CDDs/CDFs, an additional set of gloves can also be worn beneath the latex gloves.
- 5.3.3 Training—Workers must be trained in the proper method of removing contaminated gloves and clothing without contacting the exterior surfaces.
- 5.3.4 Personal hygiene—Hands and forearms should be washed thoroughly after each manipulation and before breaks (coffee, lunch, and shift).
- 5.3.5 Confinement—Isolated work areas posted with signs, segregated glassware and tools, and plastic absorbent paper on bench tops will aid in confining contamination.
- 5.3.6 Effluent vapors—The effluents of sample splitters from the gas chromatograph (GC) and from roughing pumps on the mass spectrometer (MS) should pass through either a column of activated charcoal or be bubbled through a trap containing oil or high-boiling alcohols to condense CDD/CDF vapors.
- 5.3.7 Waste Handling—Good technique includes minimizing contaminated waste. Plastic bag liners should be used in waste cans. Janitors and other personnel must be trained in the safe handling of waste.
- 5.3.8 Decontamination
 - 5.3.8.1 Decontamination of personnel—Use any mild soap with plenty of scrubbing action.
 - 5.3.8.2 Glassware, tools, and surfaces—Chlorothene NU Solvent is the least toxic solvent shown to be effective. Satisfactory cleaning may be accomplished by rinsing with Chlorothene, then washing with any detergent and water. If glassware is first rinsed with solvent, then the dish water may be disposed of in the sewer. Given the cost of disposal, it is prudent to minimize solvent wastes.
- 5.3.9 Laundry—Clothing known to be contaminated should be collected in plastic bags. Persons who convey the bags and launder the clothing should be advised of the

hazard and trained in proper handling. The clothing may be put into a washer without contact if the launderer knows of the potential problem. The washer should be run through a cycle before being used again for other clothing.

- 5.3.10 Wipe tests—A useful method of determining cleanliness of work surfaces and tools is to wipe the surface with a piece of filter paper. Extraction and analysis by GC with an electron capture detector (ECD) can achieve a limit of detection of 0.1 µg per wipe; analysis using this method can achieve an even lower detection limit. Less than 0.1 µg per wipe indicates acceptable cleanliness; anything higher warrants further cleaning. More than 10 µg on a wipe constitutes an acute hazard and requires prompt cleaning before further use of the equipment or work space, and indicates that unacceptable work practices have been employed.
- 5.3.11 Table or wrist-action shaker—The use of a table or wrist-action shaker for extraction of tissues presents the possibility of breakage of the extraction bottle and spillage of acid and flammable organic solvent. A secondary containment system around the shaker is suggested to prevent the spread of acid and solvents in the event of such a breakage. The speed and intensity of shaking action should also be adjusted to minimize the possibility of breakage.

6.0 Apparatus and Materials

NOTE: Brand names, suppliers, and part numbers are for illustration purposes only and no endorsement is implied. Equivalent performance may be achieved using apparatus and materials other than those specified here. Meeting the performance requirements of this method is the responsibility of the laboratory.

6.1 Sampling Equipment for Discrete or Composite Sampling

6.1.1 Sample bottles and caps

6.1.1.1 Liquid samples (waters, sludges and similar materials containing 5% solids or less)—Sample bottle, amber glass, 1.1 L minimum, with screw cap.

6.1.1.2 Solid samples (soils, sediments, sludges, paper pulps, filter cake, compost, and similar materials that contain more than 5% solids)—Sample bottle, wide mouth, amber glass, 500 mL minimum.

6.1.1.3 If amber bottles are not available, samples shall be protected from light.

6.1.1.4 Bottle caps—Threaded to fit sample bottles. Caps shall be lined with fluoropolymer.

6.1.1.5 Cleaning

6.1.1.5.1 Bottles are detergent water washed, then solvent rinsed before use.

- 6.1.1.5.2 Liners are detergent water washed, rinsed with reagent water (Section 7.6.1) followed by solvent, and baked at approximately 200°C for a minimum of 1 hour prior to use.
- 6.1.2 Compositing equipment—Automatic or manual compositing system incorporating glass containers cleaned per bottle cleaning procedure above. Only glass or fluoropolymer tubing shall be used. If the sampler uses a peristaltic pump, a minimum length of compressible silicone rubber tubing may be used in the pump only. Before use, the tubing shall be thoroughly rinsed with methanol, followed by repeated rinsing with reagent water to minimize sample contamination. An integrating flow meter is used to collect proportional composite samples.
- 6.2 Equipment for Glassware Cleaning—Laboratory sink with overhead fume hood.
- 6.3 Equipment for Sample Preparation
 - 6.3.1 Laboratory fume hood of sufficient size to contain the sample preparation equipment listed below.
 - 6.3.2 Glove box (optional).
 - 6.3.3 Tissue homogenizer—VirTis Model 45 Macro homogenizer (American Scientific Products H-3515, or equivalent) with stainless steel Macro-shaft and Turbo-shear blade.
 - 6.3.4 Meat grinder—Hobart, or equivalent, with 3-5 mm holes in inner plate.
 - 6.3.5 Equipment for determining percent moisture
 - 6.3.5.1 Oven—Capable of maintaining a temperature of 110 ±5°C.
 - 6.3.5.2 Dessicator.
 - 6.3.6 Balances
 - 6.3.6.1 Analytical—Capable of weighing 0.1 mg.
 - 6.3.6.2 Top loading—Capable of weighing 10 mg.
- 6.4 Extraction Apparatus
 - 6.4.1 Water samples
 - 6.4.1.1 pH meter, with combination glass electrode.
 - 6.4.1.2 pH paper, wide range (Hydrion Papers, or equivalent).
 - 6.4.1.3 Graduated cylinder, 1 L capacity.
 - 6.4.1.4 Liquid/liquid extraction—Separatory funnels, 250 mL, 500 mL, and 2000 mL, with fluoropolymer stopcocks.

6.4.1.5 Solid-phase extraction

- 6.4.1.5.1 One liter filtration apparatus, including glass funnel, glass frit support, clamp, adapter, stopper, filtration flask, and vacuum tubing (Figure 4). For wastewater samples, the apparatus should accept 90 or 144 mm disks. For drinking water or other samples containing low solids, smaller disks may be used.
- 6.4.1.5.2 Vacuum source capable of maintaining 25 in. Hg, equipped with shutoff valve and vacuum gauge.
- 6.4.1.5.3 Glass-fiber filter—Whatman GMF 150 (or equivalent), 1 micron pore size, to fit filtration apparatus in Section 6.4.1.5.1.
- 6.4.1.5.4 Solid-phase extraction disk containing octadecyl (C_{18}) bonded silica uniformly enmeshed in an inert matrix—Fisher Scientific 14-378F (or equivalent), to fit filtration apparatus in Section 6.4.1.5.1.

6.4.2 Soxhlet/Dean-Stark (SDS) extractor (Figure 5)—For filters and solid/sludge samples.

- 6.4.2.1 Soxhlet—50 mm ID, 200 mL capacity with 500 mL flask (Cal-Glass LG-6900, or equivalent, except substitute 500 mL round-bottom flask for 300 mL flat-bottom flask).
- 6.4.2.2 Thimble—43 x 123 to fit Soxhlet (Cal-Glass LG-6901-122, or equivalent).
- 6.4.2.3 Moisture trap—Dean Stark or Barret with fluoropolymer stopcock, to fit Soxhlet.
- 6.4.2.4 Heating mantle—Hemispherical, to fit 500 mL round-bottom flask (Cal-Glass LG-8801-112, or equivalent).
- 6.4.2.5 Variable transformer—Powerstat (or equivalent), 110 volt, 10 amp.

6.4.3 Apparatus for extraction of tissue.

- 6.4.3.1 Bottle for extraction (if digestion/extraction using HCl is used)—500-600 mL wide-mouth clear glass, with fluoropolymer-lined cap.
- 6.4.3.2 Bottle for back-extraction—100-200 mL narrow-mouth clear glass with fluoropolymer-lined cap.
- 6.4.3.3 Mechanical shaker—Wrist-action or platform-type rotary shaker that produces vigorous agitation (Sybron Thermolyne Model LE "Big Bill" rotator/shaker, or equivalent).

6.4.3.4 Rack attached to shaker table to permit agitation of four to nine samples simultaneously.

6.4.4 Beakers—400-500 mL.

6.4.5 Spatulas—Stainless steel.

6.5 Filtration Apparatus

6.5.1 Pyrex glass wool—Solvent-extracted by SDS for three hours minimum.

NOTE: *Baking glass wool may cause active sites that will irreversibly adsorb CDDs/CDFs.*

6.5.2 Glass funnel—125-250 mL.

6.5.3 Glass-fiber filter paper—Whatman GF/D (or equivalent), to fit glass funnel in Section 6.5.2.

6.5.4 Drying column—15-20 mm ID Pyrex chromatographic column equipped with coarse-glass frit or glass-wool plug.

6.5.5 Buchner funnel—15 cm.

6.5.6 Glass-fiber filter paper—to fit Buchner funnel in Section 6.5.5.

6.5.7 Filtration flasks—1.5-2.0 L, with side arm.

6.5.8 Pressure filtration apparatus—Millipore YT30 142 HW, or equivalent.

6.6 Centrifuge Apparatus

6.6.1 Centrifuge—Capable of rotating 500 mL centrifuge bottles or 15 mL centrifuge tubes at 5,000 rpm minimum.

6.6.2 Centrifuge bottles—500 mL, with screw-caps, to fit centrifuge.

6.6.3 Centrifuge tubes—12-15 mL, with screw-caps, to fit centrifuge.

6.7 Cleanup Apparatus

6.7.1 Automated gel permeation chromatograph (Analytical Biochemical Labs, Inc, Columbia, MO, Model GPC Autoprep 1002, or equivalent).

6.7.1.1 Column—600-700 mm long x 25 mm ID, packed with 70 g of SX-3 Bio-beads (Bio-Rad Laboratories, Richmond, CA, or equivalent).

6.7.1.2 Syringe—10 mL, with Luer fitting.

6.7.1.3 Syringe filter holder—stainless steel, and glass-fiber or fluoropolymer filters (Gelman 4310, or equivalent).

-
- 6.7.1.4 UV detectors—254 nm, preparative or semi-preparative flow cell (Isco, Inc., Type 6; Schmadzu, 5 mm path length; Beckman-Altex 152W, 8 μ L micro-prep flow cell, 2 mm path; Pharmacia UV-1, 3 mm flow cell; LDC Milton-Roy UV-3, monitor #1203; or equivalent).
- 6.7.2 Reverse-phase high-performance liquid chromatograph.
- 6.7.2.1 Column oven and detector—Perkin-Elmer Model LC-65T (or equivalent) operated at 0.02 AUFS at 235 nm.
- 6.7.2.2 Injector—Rheodyne 7120 (or equivalent) with 50 μ L sample loop.
- 6.7.2.3 Column—Two 6.2 mm x 250 mm Zorbax-ODS columns in series (DuPont Instruments Division, Wilmington, DE, or equivalent), operated at 50°C with 2.0 mL/min methanol isocratic effluent.
- 6.7.2.4 Pump—Altex 110A (or equivalent).
- 6.7.3 Pipets
- 6.7.3.1 Disposable, pasteur—150 mm long x 5-mm ID (Fisher Scientific 13-678-6A, or equivalent).
- 6.7.3.2 Disposable, serological—10 mL (6 mm ID).
- 6.7.4 Glass chromatographic columns
- 6.7.4.1 150 mm long x 8-mm ID, (Kontes K-420155, or equivalent) with coarse-glass frit or glass-wool plug and 250 mL reservoir.
- 6.7.4.2 200 mm long x 15 mm ID, with coarse-glass frit or glass-wool plug and 250 mL reservoir.
- 6.7.4.3 300 mm long x 25 mm ID, with 300 mL reservoir and glass or fluoropolymer stopcock.
- 6.7.5 Stirring apparatus for batch silica cleanup of tissue extracts.
- 6.7.5.1 Mechanical stirrer—Corning Model 320, or equivalent.
- 6.7.5.2 Bottle—500-600 mL wide-mouth clear glass.
- 6.7.6 Oven—For baking and storage of adsorbents, capable of maintaining a constant temperature ($\pm 5^\circ\text{C}$) in the range of 105-250°C.
- 6.8 Concentration Apparatus
- 6.8.1 Rotary evaporator—Buchi/Brinkman-American Scientific No. E5045-10 or equivalent, equipped with a variable temperature water bath.

- 6.8.1.1 Vacuum source for rotary evaporator equipped with shutoff valve at the evaporator and vacuum gauge.
- 6.8.1.2 A recirculating water pump and chiller are recommended, as use of tap water for cooling the evaporator wastes large volumes of water and can lead to inconsistent performance as water temperatures and pressures vary.
- 6.8.1.3 Round-bottom flask—100 mL and 500 mL or larger, with ground-glass fitting compatible with the rotary evaporator.
- 6.8.2 Kuderna-Danish (K-D) Concentrator
 - 6.8.2.1 Concentrator tube—10 mL, graduated (Kontes K-570050-1025, or equivalent) with calibration verified. Ground-glass stopper (size 19/22 joint) is used to prevent evaporation of extracts.
 - 6.8.2.2 Evaporation flask—500 mL (Kontes K-570001-0500, or equivalent), attached to concentrator tube with springs (Kontes K-662750-0012 or equivalent).
 - 6.8.2.3 Snyder column—Three-ball macro (Kontes K-503000-0232, or equivalent).
 - 6.8.2.4 Boiling chips
 - 6.8.2.4.1 Glass or silicon carbide—Approximately 10/40 mesh, extracted with methylene chloride and baked at 450°C for one hour minimum.
 - 6.8.2.4.2 Fluoropolymer (optional)—Extracted with methylene chloride.
 - 6.8.2.5 Water bath—Heated, with concentric ring cover, capable of maintaining a temperature within $\pm 2^\circ\text{C}$, installed in a fume hood.
- 6.8.3 Nitrogen blowdown apparatus—Equipped with water bath controlled in the range of 30-60°C (N-Evap, Organomation Associates, Inc., South Berlin, MA, or equivalent), installed in a fume hood.
- 6.8.4 Sample vials
 - 6.8.4.1 Amber glass—2-5 mL with fluoropolymer-lined screw-cap.
 - 6.8.4.2 Glass—0.3 mL, conical, with fluoropolymer-lined screw or crimp cap.
- 6.9 Gas Chromatograph—Shall have splitless or on-column injection port for capillary column, temperature program with isothermal hold, and shall meet all of the performance specifications in Section 10.
 - 6.9.1 GC column for CDDs/CDFs and for isomer specificity for 2,3,7,8-TCDD—60 \pm 5 m long x 0.32 \pm 0.02 mm ID; 0.25 μm 5% phenyl, 94% methyl, 1% vinyl silicone bonded-phase fused-silica capillary column (J&W DB-5, or equivalent).

- 6.9.2 GC column for isomer specificity for 2,3,7,8-TCDF—30 ±5 m long x 0.32 ±0.02 mm ID; 0.25 µm bonded-phase fused-silica capillary column (J&W DB-225, or equivalent).
- 6.10 Mass Spectrometer—28-40 eV electron impact ionization, shall be capable of repetitively selectively monitoring 12 exact m/z's minimum at high resolution (≥10,000) during a period of approximately one second, and shall meet all of the performance specifications in Section 10.
- 6.11 GC/MS Interface—The mass spectrometer (MS) shall be interfaced to the GC such that the end of the capillary column terminates within 1 cm of the ion source but does not intercept the electron or ion beams.
- 6.12 Data System—Capable of collecting, recording, and storing MS data.

7.0 Reagents and Standards

7.1 pH Adjustment and Back-Extraction

- 7.1.1 Potassium hydroxide—Dissolve 20 g reagent grade KOH in 100 mL reagent water.
- 7.1.2 Sulfuric acid—Reagent grade (specific gravity 1.84).
- 7.1.3 Hydrochloric acid—Reagent grade, 6N.
- 7.1.4 Sodium chloride—Reagent grade, prepare at 5% (w/v) solution in reagent water.

7.2 Solution Drying and Evaporation

- 7.2.1 Solution drying—Sodium sulfate, reagent grade, granular, anhydrous (Baker 3375, or equivalent), rinsed with methylene chloride (20 mL/g), baked at 400°C for one hour minimum, cooled in a dessicator, and stored in a pre-cleaned glass bottle with screw-cap that prevents moisture from entering. If, after heating, the sodium sulfate develops a noticeable grayish cast (due to the presence of carbon in the crystal matrix), that batch of reagent is not suitable for use and should be discarded. Extraction with methylene chloride (as opposed to simple rinsing) and baking at a lower temperature may produce sodium sulfate that is suitable for use.
- 7.2.2 Tissue drying—Sodium sulfate, reagent grade, powdered, treated and stored as above.
- 7.2.3 Prepurified nitrogen.

7.3 Extraction

- 7.3.1 Solvents—Acetone, toluene, cyclohexane, hexane, methanol, methylene chloride, and nonane; distilled in glass, pesticide quality, lot-certified to be free of interferences.

- 7.3.2 White quartz sand, 60/70 mesh—For Soxhlet/Dean-Stark extraction (Aldrich Chemical, Cat. No. 27-437-9, or equivalent). Bake at 450°C for four hours minimum.
- 7.4 GPC Calibration Solution—Prepare a solution containing 300 mg/mL corn oil, 15 mg/mL bis(2-ethylhexyl) phthalate, 1.4 mg/mL pentachlorophenol, 0.1 mg/mL perylene, and 0.5 mg/mL sulfur.
- 7.5 Adsorbents for Sample Cleanup
- 7.5.1 Silica gel
- 7.5.1.1 Activated silica gel—100-200 mesh, Supelco 1-3651 (or equivalent), rinsed with methylene chloride, baked at 180°C for a minimum of one hour, cooled in a dessicator, and stored in a precleaned glass bottle with screw-cap that prevents moisture from entering.
- 7.5.1.2 Acid silica gel (30% w/w)—Thoroughly mix 44.0 g of concentrated sulfuric acid with 100.0 g of activated silica gel in a clean container. Break up aggregates with a stirring rod until a uniform mixture is obtained. Store in a bottle with a fluoropolymer-lined screw-cap.
- 7.5.1.3 Basic silica gel—Thoroughly mix 30 g of 1N sodium hydroxide with 100 g of activated silica gel in a clean container. Break up aggregates with a stirring rod until a uniform mixture is obtained. Store in a bottle with a fluoropolymer-lined screw-cap.
- 7.5.1.4 Potassium silicate
- 7.5.1.4.1 Dissolve 56 g of high purity potassium hydroxide (Aldrich, or equivalent) in 300 mL of methanol in a 750-1000 mL flat-bottom flask.
- 7.5.1.4.2 Add 100 g of silica gel and a stirring bar, and stir on a hot plate at 60-70°C for one to two hours.
- 7.5.1.4.3 Decant the liquid and rinse the potassium silicate twice with 100 mL portions of methanol, followed by a single rinse with 100 mL of methylene chloride.
- 7.5.1.4.4 Spread the potassium silicate on solvent-rinsed aluminum foil and dry for two to four hours in a hood.
- 7.5.1.4.5 Activate overnight at 200-250°C.
- 7.5.2 Alumina—Either one of two types of alumina, acid or basic, may be used in the cleanup of sample extracts, provided that the laboratory can meet the performance specifications for the recovery of labeled compounds described in Section 9.3. The same type of alumina must be used for all samples, including those used to demonstrate initial precision and recovery (Section 9.2) and ongoing precision and recovery (Section 15.5).

-
- 7.5.2.1 Acid alumina—Supelco 19996-6C (or equivalent). Activate by heating to 130°C for a minimum of 12 hours.
- 7.5.2.2 Basic alumina—Supelco 19944-6C (or equivalent). Activate by heating to 600°C for a minimum of 24 hours. Alternatively, activate by heating in a tube furnace at 650-700°C under an air flow rate of approximately 400 cc/minute. Do not heat over 700°C, as this can lead to reduced capacity for retaining the analytes. Store at 130°C in a covered flask. Use within five days of baking.
- 7.5.3 Carbon
- 7.5.3.1 Carbpak C—(Supelco 1-0258, or equivalent).
- 7.5.3.2 Celite 545—(Supelco 2-0199, or equivalent).
- 7.5.3.3 Thoroughly mix 9.0 g Carbpak C and 41.0 g Celite 545 to produce an 18% w/w mixture. Activate the mixture at 130°C for a minimum of six hours. Store in a desiccator.
- 7.5.4 Anthropogenic isolation column—Pack the column in Section 6.7.4.3 from bottom to top with the following:
- 7.5.4.1 2 g silica gel (Section 7.5.1.1).
- 7.5.4.2 2 g potassium silicate (Section 7.5.1.4).
- 7.5.4.3 2 g granular anhydrous sodium sulfate (Section 7.2.1).
- 7.5.4.4 10 g acid silica gel (Section 7.5.1.2).
- 7.5.4.5 2 g granular anhydrous sodium sulfate.
- 7.5.5 Florisil column
- 7.5.5.1 Florisil—60-100 mesh, Floridin Corp (or equivalent). Soxhlet extract in 500 g portions for 24 hours.
- 7.5.5.2 Insert a glass wool plug into the tapered end of a graduated serological pipet (Section 6.7.3.2). Pack with 1.5 g (approx 2 mL) of Florisil topped with approx 1 mL of sodium sulfate (Section 7.2.1) and a glass wool plug.
- 7.5.5.3 Activate in an oven at 130-150°C for a minimum of 24 hours and cool for 30 minutes. Use within 90 minutes of cooling.
- 7.6 Reference Matrices—Matrices in which the CDDs/CDFs and interfering compounds are not detected by this method.
- 7.6.1 Reagent water—Bottled water purchased locally, or prepared by passage through activated carbon.

- 7.6.2 High-solids reference matrix—Playground sand or similar material. Prepared by extraction with methylene chloride and/or baking at 450°C for a minimum of four hours.
- 7.6.3 Paper reference matrix—Glass-fiber filter, Gelman Type A, or equivalent. Cut paper to simulate the surface area of the paper sample being tested.
- 7.6.4 Tissue reference matrix—Corn or other vegetable oil. May be prepared by extraction with methylene chloride.
- 7.6.5 Other matrices—This method may be verified on any reference matrix by performing the tests given in Section 9.2. Ideally, the matrix should be free of the CDDs/CDFs, but in no case shall the background level of the CDDs/CDFs in the reference matrix exceed three times the minimum levels in Table 2. If low background levels of the CDDs/CDFs are present in the reference matrix, the spike level of the analytes used in Section 9.2 should be increased to provide a spike-to-background ratio in the range of 1:1 to 5:1 (Reference 15).
- 7.7 Standard Solutions—Purchased as solutions or mixtures with certification to their purity, concentration, and authenticity, or prepared from materials of known purity and composition. If the chemical purity is 98% or greater, the weight may be used without correction to compute the concentration of the standard. When not being used, standards are stored in the dark at room temperature in screw-capped vials with fluoropolymer-lined caps. A mark is placed on the vial at the level of the solution so that solvent loss by evaporation can be detected. If solvent loss has occurred, the solution should be replaced.
- 7.8 Stock Solutions
- 7.8.1 Preparation—Prepare in nonane per the steps below or purchase as dilute solutions (Cambridge Isotope Laboratories (CIL), Woburn, MA, or equivalent). Observe the safety precautions in Section 5, and the recommendation in Section 5.1.2.
- 7.8.2 Dissolve an appropriate amount of assayed reference material in solvent. For example, weigh 1-2 mg of 2,3,7,8-TCDD to three significant figures in a 10 mL ground-glass-stoppered volumetric flask and fill to the mark with nonane. After the TCDD is completely dissolved, transfer the solution to a clean 15 mL vial with fluoropolymer-lined cap.
- 7.8.3 Stock standard solutions should be checked for signs of degradation prior to the preparation of calibration or performance test standards. Reference standards that can be used to determine the accuracy of calibration standards are available from CIL and may be available from other vendors.
- 7.9 PAR Stock Solution
- 7.9.1 All CDDs/CDFs—Using the solutions in Section 7.8, prepare the PAR stock solution to contain the CDDs/CDFs at the concentrations shown in Table 3. When diluted, the solution will become the PAR (Section 7.14).

- 7.9.2 If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, prepare the PAR stock solution to contain these compounds only.
- 7.10 Labeled-Compound Spiking Solution
- 7.10.1 All CDDs/CDFs—From stock solutions, or from purchased mixtures, prepare this solution to contain the labeled compounds in nonane at the concentrations shown in Table 3. This solution is diluted with acetone prior to use (Section 7.10.3).
- 7.10.2 If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, prepare the labeled-compound solution to contain these compounds only. This solution is diluted with acetone prior to use (Section 7.10.3).
- 7.10.3 Dilute a sufficient volume of the labeled compound solution (Section 7.10.1 or 7.10.2) by a factor of 50 with acetone to prepare a diluted spiking solution. Each sample requires 1.0 mL of the diluted solution, but no more solution should be prepared than can be used in one day.
- 7.11 Cleanup Standard—Prepare $^{37}\text{Cl}_4$ -2,3,7,8-TCDD in nonane at the concentration shown in Table 3. The cleanup standard is added to all extracts prior to cleanup to measure the efficiency of the cleanup process.
- 7.12 Internal Standard(s)
- 7.12.1 All CDDs/CDFs—Prepare the internal standard solution to contain $^{13}\text{C}_{12}$ -1,2,3,4-TCDD and $^{13}\text{C}_{12}$ -1,2,3,7,8,9-HxCDD in nonane at the concentration shown in Table 3.
- 7.12.2 If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, prepare the internal standard solution to contain $^{13}\text{C}_{12}$ -1,2,3,4-TCDD only.
- 7.13 Calibration Standards (CS1 through CS5)—Combine the solutions in Sections 7.9 through 7.12 to produce the five calibration solutions shown in Table 4 in nonane. These solutions permit the relative response (labeled to native) and response factor to be measured as a function of concentration. The CS3 standard is used for calibration verification (VER). If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, combine the solutions appropriate to these compounds.
- 7.14 Precision and Recovery (PAR) Standard—Used for determination of initial (Section 9.2) and ongoing (Section 15.5) precision and recovery. Dilute 10 μL of the precision and recovery standard (Section 7.9.1 or 7.9.2) to 2.0 mL with acetone for each sample matrix for each sample batch. One mL each are required for the blank and OPR with each matrix in each batch.
- 7.15 GC Retention Time Window Defining Solution and Isomer Specificity Test Standard—Used to define the beginning and ending retention times for the dioxin and furan isomers and to demonstrate isomer specificity of the GC columns employed for determination of 2,3,7,8-TCDD and 2,3,7,8-TCDF. The standard must contain the compounds listed in Table 5 (CIL EDF-4006, or equivalent), at a minimum. It is not necessary to monitor the window-defining compounds if only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be

determined. In this case, an isomer-specificity test standard containing the most closely eluted isomers listed in Table 5 (CIL EDF-4033, or equivalent) may be used.

- 7.16 QC Check Sample—A QC Check Sample should be obtained from a source independent of the calibration standards. Ideally, this check sample would be a certified reference material containing the CDDs/CDFs in known concentrations in a sample matrix similar to the matrix under test.
- 7.17 Stability of Solutions—Standard solutions used for quantitative purposes (Sections 7.9 through 7.15) should be analyzed periodically, and should be assayed against reference standards (Section 7.8.3) before further use.

8.0 Sample Collection, Preservation, Storage, and Holding Times

- 8.1 Collect samples in amber glass containers following conventional sampling practices (Reference 16). Aqueous samples that flow freely are collected in refrigerated bottles using automatic sampling equipment. Solid samples are collected as grab samples using wide-mouth jars.
- 8.2 Maintain aqueous samples in the dark at 0-4°C from the time of collection until receipt at the laboratory. If residual chlorine is present in aqueous samples, add 80 mg sodium thiosulfate per liter of water. EPA Methods 330.4 and 330.5 may be used to measure residual chlorine (Reference 17). If sample pH is greater than 9, adjust to pH 7-9 with sulfuric acid.

Maintain solid, semi-solid, oily, and mixed-phase samples in the dark at <4°C from the time of collection until receipt at the laboratory.

Store aqueous samples in the dark at 0-4°C. Store solid, semi-solid, oily, mixed-phase, and tissue samples in the dark at <-10°C.

8.3 Fish and Tissue Samples

- 8.3.1 Fish may be cleaned, filleted, or processed in other ways in the field, such that the laboratory may expect to receive whole fish, fish fillets, or other tissues for analysis.
- 8.3.2 Fish collected in the field should be wrapped in aluminum foil, and must be maintained at a temperature less than 4°C from the time of collection until receipt at the laboratory.
- 8.3.3 Samples must be frozen upon receipt at the laboratory and maintained in the dark at <-10°C until prepared. Maintain unused sample in the dark at <-10°C.

8.4 Holding Times

- 8.4.1 There are no demonstrated maximum holding times associated with CDDs/CDFs in aqueous, solid, semi-solid, tissues, or other sample matrices. If stored in the dark at 0-4°C and preserved as given above (if required), aqueous samples may be stored for up to one year. Similarly, if stored in the dark at <-10°C, solid, semi-solid, multi-phase, and tissue samples may be stored for up to one year.

- 8.4.2 Store sample extracts in the dark at $<-10^{\circ}\text{C}$ until analyzed. If stored in the dark at $<-10^{\circ}\text{C}$, sample extracts may be stored for up to one year.

9.0 Quality Assurance/Quality Control

- 9.1 Each laboratory that uses this method is required to operate a formal quality assurance program (Reference 18). The minimum requirements of this program consist of an initial demonstration of laboratory capability, analysis of samples spiked with labeled compounds to evaluate and document data quality, and analysis of standards and blanks as tests of continued performance. Laboratory performance is compared to established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

If the method is to be applied to sample matrix other than water (e.g., soils, filter cake, compost, tissue) the most appropriate alternate matrix (Sections 7.6.2 through 7.6.5) is substituted for the reagent water matrix (Section 7.6.1) in all performance tests.

- 9.1.1 The analyst shall make an initial demonstration of the ability to generate acceptable accuracy and precision with this method. This ability is established as described in Section 9.2.

- 9.1.2 In recognition of advances that are occurring in analytical technology, and to allow the analyst to overcome sample matrix interferences, the analyst is permitted certain options to improve separations or lower the costs of measurements. These options include alternate extraction, concentration, cleanup procedures, and changes in columns and detectors. Alternate determinative techniques, such as the substitution of spectroscopic or immuno-assay techniques, and changes that degrade method performance, are not allowed. If an analytical technique other than the techniques specified in this method is used, that technique must have a specificity equal to or better than the specificity of the techniques in this method for the analytes of interest.

- 9.1.2.1 Each time a modification is made to this method, the analyst is required to repeat the procedure in Section 9.2. If the detection limit of the method will be affected by the change, the laboratory is required to demonstrate that the MDL (40 CFR Part 136, Appendix B) is lower than one-third the regulatory compliance level or one-third the ML in this method, whichever is higher. If calibration will be affected by the change, the analyst must recalibrate the instrument per Section 10.

- 9.1.2.2 The laboratory is required to maintain records of modifications made to this method. These records include the following, at a minimum:

9.1.2.2.1 The names, titles, addresses, and telephone numbers of the analyst(s) who performed the analyses and modification, and of the quality control officer who witnessed and will verify the analyses and modifications.

9.1.2.2.2 A listing of pollutant(s) measured, by name and CAS Registry number.

- 9.1.2.2.3 A narrative stating reason(s) for the modifications.
- 9.1.2.2.4 Results from all quality control (QC) tests comparing the modified method to this method, including:
 - a) Calibration (Section 10.5 through 10.7).
 - b) Calibration verification (Section 15.3).
 - c) Initial precision and recovery (Section 9.2).
 - d) Labeled compound recovery (Section 9.3).
 - e) Analysis of blanks (Section 9.5).
 - f) Accuracy assessment (Section 9.4).
- 9.1.2.2.5 Data that will allow an independent reviewer to validate each determination by tracing the instrument output (peak height, area, or other signal) to the final result. These data are to include:
 - a) Sample numbers and other identifiers.
 - b) Extraction dates.
 - c) Analysis dates and times.
 - d) Analysis sequence/run chronology.
 - e) Sample weight or volume (Section 11).
 - f) Extract volume prior to each cleanup step (Section 13).
 - g) Extract volume after each cleanup step (Section 13).
 - h) Final extract volume prior to injection (Section 14).
 - I) Injection volume (Section 14.3).
 - j) Dilution data, differentiating between dilution of a sample or extract (Section 17.5).
 - k) Instrument and operating conditions.
 - l) Column (dimensions, liquid phase, solid support, film thickness, etc).
 - m) Operating conditions (temperatures, temperature program, flow rates).
 - n) Detector (type, operating conditions, etc).
 - o) Chromatograms, printer tapes, and other recordings of raw data.
 - p) Quantitation reports, data system outputs, and other data to link the raw data to the results reported.
- 9.1.3 Analyses of method blanks are required to demonstrate freedom from contamination (Section 4.3). The procedures and criteria for analysis of a method blank are described in Sections 9.5 and 15.6.
- 9.1.4 The laboratory shall spike all samples with labeled compounds to monitor method performance. This test is described in Section 9.3. When results of these spikes indicate atypical method performance for samples, the samples are diluted to bring method performance within acceptable limits. Procedures for dilution are given in Section 17.5.
- 9.1.5 The laboratory shall, on an ongoing basis, demonstrate through calibration verification and the analysis of the ongoing precision and recovery aliquot that

the analytical system is in control. These procedures are described in Sections 15.1 through 15.5.

- 9.1.6 The laboratory shall maintain records to define the quality of data that is generated. Development of accuracy statements is described in Section 9.4.
- 9.2 Initial Precision and Recovery (IPR)—To establish the ability to generate acceptable precision and recovery, the analyst shall perform the following operations.
- 9.2.1 For low solids (aqueous) samples, extract, concentrate, and analyze four 1 L aliquots of reagent water spiked with the diluted labeled compound spiking solution (Section 7.10.3) and the precision and recovery standard (Section 7.14) according to the procedures in Sections 11 through 18. For an alternative sample matrix, four aliquots of the alternative reference matrix (Section 7.6) are used. All sample processing steps that are to be used for processing samples, including preparation (Section 11), extraction (Section 12), and cleanup (Section 13), shall be included in this test.
- 9.2.2 Using results of the set of four analyses, compute the average concentration (X) of the extracts in ng/mL and the standard deviation of the concentration (s) in ng/mL for each compound, by isotope dilution for CDDs/CDFs with a labeled analog, and by internal standard for 1,2,3,7,8,9-HxCDD, OCDF, and the labeled compounds.
- 9.2.3 For each CDD/CDF and labeled compound, compare s and X with the corresponding limits for initial precision and recovery in Table 6. If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, compare s and X with the corresponding limits for initial precision and recovery in Table 6a. If s and X for all compounds meet the acceptance criteria, system performance is acceptable and analysis of blanks and samples may begin. If, however, any individual s exceeds the precision limit or any individual X falls outside the range for accuracy, system performance is unacceptable for that compound. Correct the problem and repeat the test (Section 9.2).
- 9.3 The laboratory shall spike all samples with the diluted labeled compound spiking solution (Section 7.10.3) to assess method performance on the sample matrix.
- 9.3.1 Analyze each sample according to the procedures in Sections 11 through 18.
- 9.3.2 Compute the percent recovery of the labeled compounds and the cleanup standard using the internal standard method (Section 17.2).
- 9.3.3 The recovery of each labeled compound must be within the limits in Table 7 when all 2,3,7,8-substituted CDDs/CDFs are determined, and within the limits in Table 7a when only 2,3,7,8-TCDD and 2,3,7,8-TCDF are determined. If the recovery of any compound falls outside of these limits, method performance is unacceptable for that compound in that sample. To overcome such difficulties, water samples are diluted and smaller amounts of soils, sludges, sediments, and other matrices are reanalyzed per Section 18.4.

- 9.4 Recovery of labeled compounds from samples should be assessed and records should be maintained.
- 9.4.1 After the analysis of five samples of a given matrix type (water, soil, sludge, pulp, etc.) for which the labeled compounds pass the tests in Section 9.3, compute the average percent recovery (R) and the standard deviation of the percent recovery (S_R) for the labeled compounds only. Express the assessment as a percent recovery interval from $R-2S_R$ to $R+2S_R$ for each matrix. For example, if $R = 90\%$ and $S_R = 10\%$ for five analyses of pulp, the recovery interval is expressed as 70-110%.
- 9.4.2 Update the accuracy assessment for each labeled compound in each matrix on a regular basis (e.g., after each 5-10 new measurements).
- 9.5 Method Blanks—Reference matrix method blanks are analyzed to demonstrate freedom from contamination (Section 4.3).
- 9.5.1 Prepare, extract, clean up, and concentrate a method blank with each sample batch (samples of the same matrix started through the extraction process on the same 12-hour shift, to a maximum of 20 samples). The matrix for the method blank shall be similar to sample matrix for the batch, e.g., a 1 L reagent water blank (Section 7.6.1), high-solids reference matrix blank (Section 7.6.2), paper matrix blank (Section 7.6.3); tissue blank (Section 7.6.4) or alternative reference matrix blank (Section 7.6.5). Analyze the blank immediately after analysis of the OPR (Section 15.5) to demonstrate freedom from contamination.
- 9.5.2 If any 2,3,7,8-substituted CDD/CDF (Table 1) is found in the blank at greater than the minimum level (Table 2) or one-third the regulatory compliance level, whichever is greater; or if any potentially interfering compound is found in the blank at the minimum level for each level of chlorination given in Table 2 (assuming a response factor of 1 relative to the $^{13}\text{C}_{12}$ -1,2,3,4-TCDD internal standard for compounds not listed in Table 1), analysis of samples is halted until the blank associated with the sample batch shows no evidence of contamination at this level. All samples must be associated with an uncontaminated method blank before the results for those samples may be reported for regulatory compliance purposes.
- 9.6 QC Check Sample—Analyze the QC Check Sample (Section 7.16) periodically to assure the accuracy of calibration standards and the overall reliability of the analytical process. It is suggested that the QC Check Sample be analyzed at least quarterly.
- 9.7 The specifications contained in this method can be met if the apparatus used is calibrated properly and then maintained in a calibrated state. The standards used for calibration (Section 10), calibration verification (Section 15.3), and for initial (Section 9.2) and ongoing (Section 15.5) precision and recovery should be identical, so that the most precise results will be obtained. A GC/MS instrument will provide the most reproducible results if dedicated to the settings and conditions required for the analyses of CDDs/CDFs by this method.

- 9.8 Depending on specific program requirements, field replicates may be collected to determine the precision of the sampling technique, and spiked samples may be required to determine the accuracy of the analysis when the internal standard method is used.

10.0 Calibration

- 10.1 Establish the operating conditions necessary to meet the minimum retention times for the internal standards in Section 10.2.4 and the relative retention times for the CDDs/CDFs in Table 2.

10.1.1 Suggested GC operating conditions:

Injector temperature:	270°C
Interface temperature:	290°C
Initial temperature:	200°C
Initial time:	Two minutes
Temperature program:	200-220°C, at 5°C/minute
	220°C for 16 minutes
	220-235°C, at 5°C/minute
	235°C for seven minutes
	235-330°C, at 5°C/minute

NOTE: All portions of the column that connect the GC to the ion source shall remain at or above the interface temperature specified above during analysis to preclude condensation of less volatile compounds.

Optimize GC conditions for compound separation and sensitivity. Once optimized, the same GC conditions must be used for the analysis of all standards, blanks, IPR and OPR aliquots, and samples.

- 10.1.2 Mass spectrometer (MS) resolution—Obtain a selected ion current profile (SICP) of each analyte in Table 3 at the two exact m/z 's specified in Table 8 and at $\geq 10,000$ resolving power by injecting an authentic standard of the CDDs/CDFs either singly or as part of a mixture in which there is no interference between closely eluted components.

10.1.2.1 The analysis time for CDDs/CDFs may exceed the long-term mass stability of the mass spectrometer. Because the instrument is operated in the high-resolution mode, mass drifts of a few ppm (e.g., 5 ppm in mass) can have serious adverse effects on instrument performance. Therefore, a mass-drift correction is mandatory and a lock-mass m/z from PFK is used for drift correction. The lock-mass m/z is dependent on the exact m/z 's monitored within each descriptor, as shown in Table 8. The level of PFK metered into the HRMS during analyses should be adjusted so that the amplitude of the most intense selected lock-mass m/z signal (regardless of the descriptor number) does not exceed 10% of the full-scale deflection for a given set of detector parameters. Under those conditions, sensitivity changes that might occur during the analysis can be more effectively monitored.

NOTE: Excessive PFK (or any other reference substance) may cause noise problems and contamination of the ion source necessitating increased frequency of source cleaning.

- 10.1.2.2 If the HRMS has the capability to monitor resolution during the analysis, it is acceptable to terminate the analysis when the resolution falls below 10,000 to save reanalysis time.
- 10.1.2.3 Using a PFK molecular leak, tune the instrument to meet the minimum required resolving power of 10,000 (10% valley) at m/z 304.9824 (PFK) or any other reference signal close to m/z 304 (from TCDF). For each descriptor (Table 8), monitor and record the resolution and exact m/z 's of three to five reference peaks covering the mass range of the descriptor. The resolution must be greater than or equal to 10,000, and the deviation between the exact m/z and the theoretical m/z (Table 8) for each exact m/z monitored must be less than 5 ppm.
- 10.2 Ion Abundance Ratios, Minimum Levels, Signal-to-Noise Ratios, and Absolute Retention Times—Choose an injection volume of either 1 μL or 2 μL , consistent with the capability of the HRGC/HRMS instrument. Inject a 1 μL or 2 μL aliquot of the CS1 calibration solution (Table 4) using the GC conditions from Section 10.1.1. If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, the operating conditions and specifications below apply to analysis of those compounds only.
- 10.2.1 Measure the SICP areas for each analyte, and compute the ion abundance ratios at the exact m/z 's specified in Table 8. Compare the computed ratio to the theoretical ratio given in Table 9.
- 10.2.1.1 The exact m/z 's to be monitored in each descriptor are shown in Table 8. Each group or descriptor shall be monitored in succession as a function of GC retention time to ensure that all CDDs/CDFs are detected. Additional m/z 's may be monitored in each descriptor, and the m/z 's may be divided among more than the five descriptors listed in Table 8, provided that the laboratory is able to monitor the m/z 's of all the CDDs/CDFs that may elute from the GC in a given retention-time window. If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, the descriptors may be modified to include only the exact m/z 's for the tetra- and penta-isomers, the diphenyl ethers, and the lock m/z 's.
- 10.2.1.2 The mass spectrometer shall be operated in a mass-drift correction mode, using perfluorokerosene (PFK) to provide lock m/z 's. The lock-mass for each group of m/z 's is shown in Table 8. Each lock mass shall be monitored and shall not vary by more than $\pm 20\%$ throughout its respective retention time window. Variations of the lock mass by more than 20% indicate the presence of coeluting interferences that may significantly reduce the sensitivity of the mass spectrometer. Reinjection of another aliquot of the sample extract will not resolve the problem. Additional cleanup of the extract may be required to remove the interferences.

- 10.2.2 All CDDs/CDFs and labeled compounds in the CS1 standard shall be within the QC limits in Table 9 for their respective ion abundance ratios; otherwise, the mass spectrometer shall be adjusted and this test repeated until the m/z ratios fall within the limits specified. If the adjustment alters the resolution of the mass spectrometer, resolution shall be verified (Section 10.1.2) prior to repeat of the test.
- 10.2.3 Verify that the HRGC/HRMS instrument meets the minimum levels in Table 2. The peaks representing the CDDs/CDFs and labeled compounds in the CS1 calibration standard must have signal-to-noise ratios (S/N) greater than or equal to 10.0. Otherwise, the mass spectrometer shall be adjusted and this test repeated until the minimum levels in Table 2 are met.
- 10.2.4 The absolute retention time of $^{13}\text{C}_{12}$ -1,2,3,4-TCDD (Section 7.12) shall exceed 25.0 minutes on the DB-5 column, and the retention time of $^{13}\text{C}_{12}$ -1,2,3,4-TCDD shall exceed 15.0 minutes on the DB-225 column; otherwise, the GC temperature program shall be adjusted and this test repeated until the above-stated minimum retention time criteria are met.
- 10.3 Retention-Time Windows—Analyze the window defining mixtures (Section 7.15) using the optimized temperature program in Section 10.1. Table 5 gives the elution order (first/last) of the window-defining compounds. If 2,3,7,8-TCDD and 2,3,7,8-TCDF only are to be analyzed, this test is not required.
- 10.4 Isomer Specificity
- 10.4.1 Analyze the isomer specificity test standards (Section 7.15) using the procedure in Section 14 and the optimized conditions for sample analysis (Section 10.1.1).
- 10.4.2 Compute the percent valley between the GC peaks that elute most closely to the 2,3,7,8-TCDD and TCDF isomers, on their respective columns, per Figures 6 and 7.
- 10.4.3 Verify that the height of the valley between the most closely eluted isomers and the 2,3,7,8-substituted isomers is less than 25% (computed as $100 \times y$ in Figures 6 and 7). If the valley exceeds 25%, adjust the analytical conditions and repeat the test or replace the GC column and recalibrate (Sections 10.1.2 through 10.7).
- 10.5 Calibration by Isotope Dilution—Isotope dilution calibration is used for the 15 2,3,7,8-substituted CDDs/CDFs for which labeled compounds are added to samples prior to extraction. The reference compound for each CDD/CDF compound is shown in Table 2.
- 10.5.1 A calibration curve encompassing the concentration range is prepared for each compound to be determined. The relative response (RR) (labeled to native) vs. concentration in standard solutions is plotted or computed using a linear regression. Relative response is determined according to the procedures described below. Five calibration points are employed.
- 10.5.2 The response of each CDD/CDF relative to its labeled analog is determined using the area responses of both the primary and secondary exact m/z's specified in Table 8, for each calibration standard, as follows:

$$RR = \frac{(A1_n + A2_n) C_l}{(A1_l + A2_l) C_n}$$

where,

A1_n and A2_n = The areas of the primary and secondary m/z's for the CDD/CDF.

A1_l and A2_l = The areas of the primary and secondary m/z's for the labeled compound.

C_l = The concentration of the labeled compound in the calibration standard (Table 4).

C_n = The concentration of the native compound in the calibration standard (Table 4).

10.5.3 To calibrate the analytical system by isotope dilution, inject a volume of calibration standards CS1 through CS5 (Section 7.13 and Table 4) identical to the volume chosen in Section 10.2, using the procedure in Section 14 and the conditions in Section 10.1.1 and Table 2. Compute the relative response (RR) at each concentration.

10.5.4 Linearity—If the relative response for any compound is constant (less than 20% coefficient of variation) over the five-point calibration range, an averaged relative response may be used for that compound; otherwise, the complete calibration curve for that compound shall be used over the five-point calibration range.

10.6 Calibration by Internal Standard—The internal standard method is applied to determination of 1,2,3,7,8,9-HxCDD (Section 17.1.2), OCDF (Section 17.1.1), the non-2,3,7,8-substituted compounds, and to the determination of labeled compounds for intralaboratory statistics (Sections 9.4 and 15.5.4).

10.6.1 Response factors—Calibration requires the determination of response factors (RF) defined by the following equation:

$$RF = \frac{(A1_s + A2_s) C_{is}}{(A1_{is} + A2_{is}) C_s}$$

where,

A1_s and A2_s = The areas of the primary and secondary m/z's for the CDD/CDF.

A1_{is} and A2_{is} = The areas of the primary and secondary m/z's for the internal standard

C_{is} = The concentration of the internal standard (Table 4).

C_s = The concentration of the compound in the calibration standard (Table 4).

NOTE: There is only one m/z for ³⁷Cl₄-2,3,7,8-TCDD. See Table 8.

10.6.2 To calibrate the analytical system by internal standard, inject 1.0 µL or 2.0 µL of calibration standards CS1 through CS5 (Section 7.13 and Table 4) using the procedure in Section 14 and the conditions in Section 10.1.1 and Table 2. Compute the response factor (RF) at each concentration.

- 10.6.3 **Linearity**—If the response factor (RF) for any compound is constant (less than 35% coefficient of variation) over the five-point calibration range, an averaged response factor may be used for that compound; otherwise, the complete calibration curve for that compound shall be used over the five-point range.
- 10.7 **Combined Calibration**—By using calibration solutions (Section 7.13 and Table 4) containing the CDDs/CDFs and labeled compounds and the internal standards, a single set of analyses can be used to produce calibration curves for the isotope dilution and internal standard methods. These curves are verified each shift (Section 15.3) by analyzing the calibration verification standard (VER, Table 4). Recalibration is required if any of the calibration verification criteria (Section 15.3) cannot be met.
- 10.8 **Data Storage**—MS data shall be collected, recorded, and stored.
- 10.8.1 **Data acquisition**—The signal at each exact m/z shall be collected repetitively throughout the monitoring period and stored on a mass storage device.
- 10.8.2 **Response factors and multipoint calibrations**—The data system shall be used to record and maintain lists of response factors (response ratios for isotope dilution) and multipoint calibration curves. Computations of relative standard deviation (coefficient of variation) shall be used to test calibration linearity. Statistics on initial performance (Section 9.2) and ongoing performance (Section 15.5) should be computed and maintained, either on the instrument data system, or on a separate computer system.

11.0 Sample Preparation

- 11.1 **Sample preparation** involves modifying the physical form of the sample so that the CDDs/CDFs can be extracted efficiently. In general, the samples must be in a liquid form or in the form of finely divided solids in order for efficient extraction to take place. Table 10 lists the phases and suggested quantities for extraction of various sample matrices.

For samples known or expected to contain high levels of the CDDs/CDFs, the smallest sample size representative of the entire sample should be used (see Section 17.5).

For all samples, the blank and IPR/OPR aliquots must be processed through the same steps as the sample to check for contamination and losses in the preparation processes.

- 11.1.1 For samples that contain particles, percent solids and particle size are determined using the procedures in Sections 11.2 and 11.3, respectively.
- 11.1.2 **Aqueous samples**—Because CDDs/CDFs may be bound to suspended particles, the preparation of aqueous samples is dependent on the solids content of the sample.
- 11.1.2.1 Aqueous samples visibly absent particles are prepared per Section 11.4 and extracted directly using the separatory funnel or SPE techniques in Sections 12.1 or 12.2, respectively.

- 11.1.2.2 Aqueous samples containing visible particles and containing one percent suspended solids or less are prepared using the procedure in Section 11.4. After preparation, the sample is extracted directly using the SPE technique in 12.2 or filtered per Section 11.4.3. After filtration, the particles and filter are extracted using the SDS procedure in Section 12.3 and the filtrate is extracted using the separatory funnel procedure in Section 12.1.
- 11.1.2.3 For aqueous samples containing greater than one percent solids, a sample aliquot sufficient to provide 10 g of dry solids is used, as described in Section 11.5.
- 11.1.3 Solid samples are prepared using the procedure described in Section 11.5 followed by extraction via the SDS procedure in Section 12.3.
- 11.1.4 Multiphase samples—The phase(s) containing the CDDs/CDFs is separated from the non-CDD/CDF phase using pressure filtration and centrifugation, as described in Section 11.6. The CDDs/CDFs will be in the organic phase in a multiphase sample in which an organic phase exists.
- 11.1.5 Procedures for grinding, homogenization, and blending of various sample phases are given in Section 11.7.
- 11.1.6 Tissue samples—Preparation procedures for fish and other tissues are given in Section 11.8.

11.2 Determination of Percent Suspended Solids

NOTE: This aliquot is used for determining the solids content of the sample, not for determination of CDDs/CDFs.

- 11.2.1 Aqueous liquids and multi-phase samples consisting of mainly an aqueous phase.
- 11.2.1.1 Dessicate and weigh a GF/D filter (Section 6.5.3) to three significant figures.
- 11.2.1.2 Filter 10.0 ±0.02 mL of well-mixed sample through the filter.
- 11.2.1.3 Dry the filter a minimum of 12 hours at 110 ±5°C and cool in a dessicator.
- 11.2.1.4 Calculate percent solids as follows:

$$\% \text{solids} = \frac{\text{weight of sample aliquot after drying (g)} - \text{weight of filter (g)}}{10 \text{ g}} \times 100$$

- 11.2.2 Non-aqueous liquids, solids, semi-solid samples, and multi-phase samples in which the main phase is not aqueous; but not tissues.
- 11.2.2.1 Weigh 5-10 g of sample to three significant figures in a tared beaker.

11.2.2.2 Dry a minimum of 12 hours at 110 ±5°C, and cool in a dessicator.

11.2.2.3 Calculate percent solids as follows:

$$\% \text{ solids} = \frac{\text{weight of sample aliquot after drying}}{\text{weight of sample aliquot before drying}} \times 100$$

11.3 Determination of Particle Size

11.3.1 Spread the dried sample from Section 11.2.2.2 on a piece of filter paper or aluminum foil in a fume hood or glove box.

11.3.2 Estimate the size of the particles in the sample. If the size of the largest particles is greater than 1 mm, the particle size must be reduced to 1 mm or less prior to extraction using the procedures in Section 11.7.

11.4 Preparation of Aqueous Samples Containing 1% Suspended Solids or Less

11.4.1 Aqueous samples visibly absent particles are prepared per the procedure below and extracted directly using the separatory funnel or SPE techniques in Sections 12.1 or 12.2, respectively. Aqueous samples containing visible particles and one percent suspended solids or less are prepared using the procedure below and extracted using either the SPE technique in Section 12.2 or further prepared using the filtration procedure in Section 11.4.3. The filtration procedure is followed by SDS extraction of the filter and particles (Section 12.3) and separatory funnel extraction of the filtrate (Section 12.1). The SPE procedure is followed by SDS extraction of the filter and disk.

11.4.2 Preparation of sample and QC aliquots

11.4.2.1 Mark the original level of the sample on the sample bottle for reference. Weigh the sample plus bottle to ±1 g.

11.4.2.2 Spike 1.0 mL of the diluted labeled-compound spiking solution (Section 7.10.3) into the sample bottle. Cap the bottle and mix the sample by careful shaking. Allow the sample to equilibrate for one to two hours, with occasional shaking.

11.4.2.3 For each sample or sample batch (to a maximum of 20 samples) to be extracted during the same 12-hour shift, place two 1.0 L aliquots of reagent water in clean sample bottles or flasks.

11.4.2.4 Spike 1.0 mL of the diluted labeled-compound spiking solution (Section 7.10.3) into both reagent water aliquots. One of these aliquots will serve as the method blank.

11.4.2.5 Spike 1.0 mL of the PAR standard (Section 7.14) into the remaining reagent water aliquot. This aliquot will serve as the OPR (Section 15.5).

- 11.4.2.6 If SPE is to be used, add 5 mL of methanol to the sample, cap and shake the sample to mix thoroughly, and proceed to Section 12.2 for extraction. If SPE is not to be used, and the sample is visibly absent particles, proceed to Section 12.1 for extraction. If SPE is not to be used and the sample contains visible particles, proceed to the following section for filtration of particles.

11.4.3 Filtration of particles

- 11.4.3.1 Assemble a Buchner funnel (Section 6.5.5) on top of a clean filtration flask. Apply vacuum to the flask, and pour the entire contents of the sample bottle through a glass-fiber filter (Section 6.5.6) in the Buchner funnel, swirling the sample remaining in the bottle to suspend any particles.
- 11.4.3.2 Rinse the sample bottle twice with approximately 5 mL portions of reagent water to transfer any remaining particles onto the filter.
- 11.4.3.3 Rinse any particles off the sides of the Buchner funnel with small quantities of reagent water.
- 11.4.3.4 Weigh the empty sample bottle to ± 1 g. Determine the weight of the sample by difference. Save the bottle for further use.
- 11.4.3.5 Extract the filtrate using the separatory funnel procedure in Section 12.1.
- 11.4.3.6 Extract the filter containing the particles using the SDS procedure in Section 12.3.

11.5 Preparation of Samples Containing Greater Than 1% Solids

- 11.5.1 Weigh a well-mixed aliquot of each sample (of the same matrix type) sufficient to provide 10 g of dry solids (based on the solids determination in Section 11.2) into a clean beaker or glass jar.
- 11.5.2 Spike 1.0 mL of the diluted labeled compound spiking solution (Section 7.10.3) into the sample.
- 11.5.3 For each sample or sample batch (to a maximum of 20 samples) to be extracted during the same 12-hour shift, weigh two 10 g aliquots of the appropriate reference matrix (Section 7.6) into clean beakers or glass jars.
- 11.5.4 Spike 1.0 mL of the diluted labeled compound spiking solution (Section 7.10.3) into each reference matrix aliquot. One aliquot will serve as the method blank. Spike 1.0 mL of the PAR standard (Section 7.14) into the other reference matrix aliquot. This aliquot will serve as the OPR (Section 15.5).
- 11.5.5 Stir or tumble and equilibrate the aliquots for one to two hours.

-
- 11.5.6 Decant excess water. If necessary to remove water, filter the sample through a glass-fiber filter and discard the aqueous liquid.
- 11.5.7 If particles >1mm are present in the sample (as determined in Section 11.3.2), spread the sample on clean aluminum foil in a hood. After the sample is dry, grind to reduce the particle size (Section 11.7).
- 11.5.8 Extract the sample and QC aliquots using the SDS procedure in Section 12.3.
- 11.6 Multiphase Samples
- 11.6.1 Using the percent solids determined in Section 11.2.1 or 11.2.2, determine the volume of sample that will provide 10 g of solids, up to 1 L of sample.
- 11.6.2 Pressure filter the amount of sample determined in Section 11.6.1 through Whatman GF/D glass-fiber filter paper (Section 6.5.3). Pressure filter the blank and OPR aliquots through GF/D papers also. If necessary to separate the phases and/or settle the solids, centrifuge these aliquots prior to filtration.
- 11.6.3 Discard any aqueous phase (if present). Remove any non-aqueous liquid present and reserve the maximum amount filtered from the sample (Section 11.6.1) or 10 g, whichever is less, for combination with the solid phase (Section 12.3.5).
- 11.6.4 If particles >1mm are present in the sample (as determined in Section 11.3.2) and the sample is capable of being dried, spread the sample and QC aliquots on clean aluminum foil in a hood. After the aliquots are dry or if the sample cannot be dried, reduce the particle size using the procedures in Section 11.7 and extract the reduced particles using the SDS procedure in Section 12.3. If particles >1mm are not present, extract the particles and filter in the sample and QC aliquots directly using the SDS procedure in Section 12.3.
- 11.7 Sample grinding, homogenization, or blending—Samples with particle sizes greater than 1 mm (as determined in Section 11.3.2) are subjected to grinding, homogenization, or blending. The method of reducing particle size to less than 1 mm is matrix-dependent. In general, hard particles can be reduced by grinding with a mortar and pestle. Softer particles can be reduced by grinding in a Wiley mill or meat grinder, by homogenization, or in a blender.
- 11.7.1 Each size-reducing preparation procedure on each matrix shall be verified by running the tests in Section 9.2 before the procedure is employed routinely.
- 11.7.2 The grinding, homogenization, or blending procedures shall be carried out in a glove box or fume hood to prevent particles from contaminating the work environment.
- 11.7.3 Grinding—Certain papers and pulps, slurries, and amorphous solids can be ground in a Wiley mill or heavy duty meat grinder. In some cases, reducing the temperature of the sample to freezing or to dry ice or liquid nitrogen temperatures can aid in the grinding process. Grind the sample aliquots from Section 11.5.7 or 11.6.4 in a clean grinder. Do not allow the sample temperature

to exceed 50°C. Grind the blank and reference matrix aliquots using a clean grinder.

11.7.4 Homogenization or blending—Particles that are not ground effectively, or particles greater than 1 mm in size after grinding, can often be reduced in size by high speed homogenization or blending. Homogenize and/or blend the particles or filter from Section 11.5.7 or 11.6.4 for the sample, blank, and OPR aliquots.

11.7.5 Extract the aliquots using the SDS procedure in Section 12.3.

11.8 Fish and Other Tissues—Prior to processing tissue samples, the laboratory must determine the exact tissue to be analyzed. Common requests for analysis of fish tissue include whole fish—skin on, whole fish—skin removed, edible fish fillets (filleted in the field or by the laboratory), specific organs, and other portions. Once the appropriate tissue has been determined, the sample must be homogenized.

11.8.1 Homogenization

11.8.1.1 Samples are homogenized while still frozen, where practical. If the laboratory must dissect the whole fish to obtain the appropriate tissue for analysis, the unused tissues may be rapidly refrozen and stored in a clean glass jar for subsequent use.

11.8.1.2 Each analysis requires 10 g of tissue (wet weight). Therefore, the laboratory should homogenize at least 20 g of tissue to allow for re-extraction of a second aliquot of the same homogenized sample, if re-analysis is required. When whole fish analysis is necessary, the entire fish is homogenized.

11.8.1.3 Homogenize the sample in a tissue homogenizer (Section 6.3.3) or grind in a meat grinder (Section 6.3.4). Cut tissue too large to feed into the grinder into smaller pieces. To assure homogeneity, grind three times.

11.8.1.4 Transfer approximately 10 g (wet weight) of homogenized tissue to a clean, tared, 400-500 mL beaker. For the alternate HCl digestion/extraction, transfer the tissue to a clean, tared 500-600 mL wide-mouth bottle. Record the weight to the nearest 10 mg.

11.8.1.5 Transfer the remaining homogenized tissue to a clean jar with a fluoropolymer-lined lid. Seal the jar and store the tissue at <-10°C. Return any tissue that was not homogenized to its original container and store at <-10°C.

11.8.2 QC aliquots

11.8.2.1 Prepare a method blank by adding approximately 10 g of the oily liquid reference matrix (Section 7.6.4) to a 400-500 mL beaker. For the alternate HCl digestion/extraction, add the reference matrix to a 500-600 mL wide-mouth bottle. Record the weight to the nearest 10 mg.

11.8.2.2 Prepare a precision and recovery aliquot by adding approximately 10 g of the oily liquid reference matrix (Section 7.6.4) to a separate 400-500 mL beaker or wide-mouth bottle, depending on the extraction procedure to be used. Record the weight to the nearest 10 mg. If the initial precision and recovery test is to be performed, use four aliquots; if the ongoing precision and recovery test is to be performed, use a single aliquot.

11.8.3 Spiking

11.8.3.1 Spike 1.0 mL of the labeled compound spiking solution (Section 7.10.3) into the sample, blank, and OPR aliquot.

11.8.3.2 Spike 1.0 mL of the PAR standard (Section 7.14) into the OPR aliquot.

11.8.4 Extract the aliquots using the procedures in Section 12.4.

12.0 Extraction and Concentration

Extraction procedures include separatory funnel (Section 12.1) and solid phase (Section 12.2) for aqueous liquids; Soxhlet/Dean-Stark (Section 12.3) for solids, filters, and SPE disks; and Soxhlet extraction (Section 12.4.1) and HCl digestion (Section 12.4.2) for tissues. Acid/base back-extraction (Section 12.5) is used for initial cleanup of extracts.

Macro-concentration procedures include rotary evaporation (Section 12.6.1), heating mantle (Section 12.6.2), and Kuderna-Danish (K-D) evaporation (Section 12.6.3). Micro-concentration uses nitrogen blowdown (Section 12.7).

12.1 Separatory funnel extraction of filtrates and of aqueous samples visibly absent particles.

12.1.1 Pour the spiked sample (Section 11.4.2.2) or filtrate (Section 11.4.3.5) into a 2 L separatory funnel. Rinse the bottle or flask twice with 5 mL of reagent water and add these rinses to the separatory funnel.

12.1.2 Add 60 mL methylene chloride to the empty sample bottle (Section 12.1.1), seal, and shake 60 seconds to rinse the inner surface. Transfer the solvent to the separatory funnel, and extract the sample by shaking the funnel for two minutes with periodic venting. Allow the organic layer to separate from the aqueous phase for a minimum of 10 minutes. If an emulsion forms and is more than one-third the volume of the solvent layer, employ mechanical techniques to complete the phase separation (see note below). Drain the methylene chloride extract through a solvent-rinsed glass funnel approximately one-half full of granular

anhydrous sodium sulfate (Section 7.2.1) supported on clean glass-fiber paper into a solvent-rinsed concentration device (Section 12.6).

NOTE: *If an emulsion forms, the analyst must employ mechanical techniques to complete the phase separation. The optimum technique depends upon the sample, but may include stirring, filtration through glass wool, use of phase separation paper, centrifugation, use of an ultrasonic bath with ice, addition of NaCl, or other physical methods. Alternatively, solid-phase or other extraction techniques may be used to prevent emulsion formation. Any alternative technique is acceptable so long as the requirements in Section 9 are met.*

Experience with aqueous samples high in dissolved organic materials (e.g., paper mill effluents) has shown that acidification of the sample prior to extraction may reduce the formation of emulsions. Paper industry methods suggest that the addition of up to 400 mL of ethanol to a 1 L effluent sample may also reduce emulsion formation. However, studies by EPA suggest that the effect may be a result of sample dilution, and that the addition of reagent water may serve the same function. Mechanical techniques may still be necessary to complete the phase separation. If either acidification or addition of ethanol is utilized, the laboratory must perform the startup tests described in Section 9.2 using the same techniques.

12.1.3 Extract the water sample two more times with 60 mL portions of methylene chloride. Drain each portion through the sodium sulfate into the concentrator. After the third extraction, rinse the separatory funnel with at least 20 mL of methylene chloride, and drain this rinse through the sodium sulfate into the concentrator. Repeat this rinse at least twice. Set aside the funnel with sodium sulfate if the extract is to be combined with the extract from the particles.

12.1.4 Concentrate the extract using one of the macro-concentration procedures in Section 12.6.

12.1.4.1 If the extract is from a sample visibly absent particles (Section 11.1.2.1), adjust the final volume of the concentrated extract to approximately 10 mL with hexane, transfer to a 250 mL separatory funnel, and back-extract using the procedure in Section 12.5.

12.1.4.2 If the extract is from the aqueous filtrate (Section 11.4.3.5), set aside the concentration apparatus for addition of the SDS extract from the particles (Section 12.3.9.1.2).

12.2 SPE of Samples Containing Less Than 1% Solids (References 19-20)

12.2.1 Disk preparation

12.2.1.1 Place an SPE disk on the base of the filter holder (Figure 4) and wet with toluene. While holding a GMF 150 filter above the SPE disk with tweezers, wet the filter with toluene and lay the filter on the SPE disk, making sure that air is not trapped between the filter and disk. Clamp the filter and SPE disk between the 1 L glass reservoir and the vacuum filtration flask.

- 12.2.1.2 Rinse the sides of the filtration flask with approx 15 mL of toluene using a squeeze bottle or syringe. Apply vacuum momentarily until a few drops appear at the drip tip. Release the vacuum and allow the filter/disk to soak for approx one minute. Apply vacuum and draw all of the toluene through the filter/disk. Repeat the wash step with approx 15 mL of acetone and allow the filter/disk to air dry.
- 12.2.1.3 Re-wet the filter/disk with approximately 15 mL of methanol, allowing the filter/disk to soak for approximately one minute. Pull the methanol through the filter/disk using the vacuum, but retain a layer of methanol approximately 1 mm thick on the filter. Do not allow the disk to go dry from this point until the end of the extraction.
- 12.2.1.4 Rinse the filter/disk with two 50-mL portions of reagent water by adding the water to the reservoir and pulling most through, leaving a layer of water on the surface of the filter.

12.2.2 Extraction

- 12.2.2.1 Pour the spiked sample (Section 11.4.2.2), blank (Section 11.4.2.4), or IPR/OPR aliquot (Section 11.4.2.5) into the reservoir and turn on the vacuum to begin the extraction. Adjust the vacuum to complete the extraction in no less than 10 minutes. For samples containing a high concentration of particles (suspended solids), filtration times may be eight hours or longer.
- 12.2.2.2 Before all of the sample has been pulled through the filter/disk, rinse the sample bottle with approximately 50 mL of reagent water to remove any solids, and pour into the reservoir. Pull through the filter/disk. Use additional reagent water rinses until all visible solids are removed.
- 12.2.2.3 Before all of the sample and rinses have been pulled through the filter/disk, rinse the sides of the reservoir with small portions of reagent water.
- 12.2.2.4 Allow the filter/disk to dry, then remove the filter and disk and place in a glass Petri dish. Extract the filter and disk per Section 12.3.

12.3 SDS Extraction of Samples Containing Particles, and of Filters and/or Disks

- 12.3.1 Charge a clean extraction thimble (Section 6.4.2.2) with 5.0 g of 100/200 mesh silica (Section 7.5.1.1) topped with 100 g of quartz sand (Section 7.3.2).

NOTE: Do not disturb the silica layer throughout the extraction process.

- 12.3.2 Place the thimble in a clean extractor. Place 30-40 mL of toluene in the receiver and 200-250 mL of toluene in the flask.

- 12.3.3 Pre-extract the glassware by heating the flask until the toluene is boiling. When properly adjusted, one to two drops of toluene will fall per second from the condenser tip into the receiver. Extract the apparatus for a minimum of three hours.
- 12.3.4 After pre-extraction, cool and disassemble the apparatus. Rinse the thimble with toluene and allow to air dry.
- 12.3.5 Load the wet sample, filter, and/or disk from Section 11.4.3.6, 11.5.8, 11.6.4, 11.7.3, 11.7.4, or 12.2.2.4 and any nonaqueous liquid from Section 11.6.3 into the thimble and manually mix into the sand layer with a clean metal spatula, carefully breaking up any large lumps of sample.
- 12.3.6 Reassemble the pre-extracted SDS apparatus, and add a fresh charge of toluene to the receiver and reflux flask. Apply power to the heating mantle to begin refluxing. Adjust the reflux rate to match the rate of percolation through the sand and silica beds until water removal lessens the restriction to toluene flow. Frequently check the apparatus for foaming during the first two hours of extraction. If foaming occurs, reduce the reflux rate until foaming subsides.
- 12.3.7 Drain the water from the receiver at one to two hours and eight to nine hours, or sooner if the receiver fills with water. Reflux the sample for a total of 16-24 hours. Cool and disassemble the apparatus. Record the total volume of water collected.
- 12.3.8 Remove the distilling flask. Drain the water from the Dean-Stark receiver and add any toluene in the receiver to the extract in the flask.
- 12.3.9 Concentrate the extract using one of the macro-concentration procedures in Section 12.6 per the following:
- 12.3.9.1 Extracts from the particles in an aqueous sample containing less than 1% solids (Section 11.4.3.6).
 - 12.3.9.1.1 Concentrate the extract to approximately 5 mL using the rotary evaporator or heating mantle procedures in Section 12.6.1 or 12.6.2.
 - 12.3.9.1.2 Quantitatively transfer the extract through the sodium sulfate (Section 12.1.3) into the apparatus that was set aside (Section 12.1.4.2) and reconcentrate to the level of the toluene.
 - 12.3.9.1.3 Adjust to approximately 10 mL with hexane, transfer to a 250 mL separatory funnel, and proceed with back-extraction (Section 12.5).
 - 12.3.9.2 Extracts from particles (Sections 11.5 through 11.6) or from the SPE filter and disk (Section 12.2.2.4)—Concentrate to approximately 10 mL using the rotary evaporator or heating mantle (Section 12.6.1

or 12.6.2), transfer to a 250 mL separatory funnel, and proceed with back-extraction (Section 12.5).

12.4 Extraction of Tissue—Two procedures are provided for tissue extraction.

12.4.1 Soxhlet extraction (Reference 21)

- 12.4.1.1 Add 30-40 g of powdered anhydrous sodium sulfate to each of the beakers (Section 11.8.4) and mix thoroughly. Cover the beakers with aluminum foil and allow to equilibrate for 12-24 hours. Remix prior to extraction to prevent clumping.
- 12.4.1.2 Assemble and pre-extract the Soxhlet apparatus per Sections 12.3.1 through 12.3.4, except use the methylene chloride:hexane (1:1) mixture for the pre-extraction and rinsing and omit the quartz sand. The Dean-Stark moisture trap may also be omitted, if desired.
- 12.4.1.3 Reassemble the pre-extracted Soxhlet apparatus and add a fresh charge of methylene chloride:hexane to the reflux flask.
- 12.4.1.4 Transfer the sample/sodium sulfate mixture (Section 12.4.1.1) to the Soxhlet thimble, and install the thimble in the Soxhlet apparatus.
- 12.4.1.5 Rinse the beaker with several portions of solvent mixture and add to the thimble. Fill the thimble/receiver with solvent. Extract for 18-24 hours.
- 12.4.1.6 After extraction, cool and disassemble the apparatus.
- 12.4.1.7 Quantitatively transfer the extract to a macro-concentration device (Section 12.6), and concentrate to near dryness. Set aside the concentration apparatus for re-use.
- 12.4.1.8 Complete the removal of the solvent using the nitrogen blowdown procedure (Section 12.7) and a water bath temperature of 60°C. Weigh the receiver, record the weight, and return the receiver to the blowdown apparatus, concentrating the residue until a constant weight is obtained.
- 12.4.1.9 Percent lipid determination—The lipid content is determined by extraction of tissue with the same solvent system (methylene chloride:hexane) that was used in EPA's National Dioxin Study (Reference 22) so that lipid contents are consistent with that study.
- 12.4.1.9.1 Redissolve the residue in the receiver in hexane and spike 1.0 mL of the cleanup standard (Section 7.11) into the solution.

12.4.1.9.2 Transfer the residue/hexane to the anthropogenic isolation column (Section 13.7.1) or bottle for the acidified silica gel batch cleanup (Section 13.7.2), retaining the boiling chips in the concentration apparatus. Use several rinses to assure that all material is transferred. If necessary, sonicate or heat the receiver slightly to assure that all material is re-dissolved. Allow the receiver to dry. Weigh the receiver and boiling chips.

12.4.1.9.3 Calculate the lipid content to the nearest three significant figures as follows:

$$\text{Percent lipid} = \frac{\text{Weight of residue (g)}}{\text{Weight of tissue (g)}} \times 100$$

12.4.1.9.4 It is not necessary to determine the lipid content of the blank, IPR, or OPR aliquots.

12.4.2 HCl digestion/extraction and concentration (References 23-26)

12.4.2.1 Add 200 mL of 6 N HCl and 200 mL of methylene chloride:hexane (1:1) to the sample and QC aliquots (Section 11.8.4).

12.4.2.2 Cap and shake each bottle one to three times. Loosen the cap in a hood to vent excess pressure. Shake each bottle for 10-30 seconds and vent.

12.4.2.3 Tightly cap and place on shaker. Adjust the shaker action and speed so that the acid, solvent, and tissue are in constant motion. However, take care to avoid such violent action that the bottle may be dislodged from the shaker. Shake for 12-24 hours.

12.4.2.4 After digestion, remove the bottles from the shaker. Allow the bottles to stand so that the solvent and acid layers separate.

12.4.2.5 Decant the solvent through a glass funnel with glass-fiber filter (Sections 6.5.2 through 6.5.3) containing approximately 10 g of granular anhydrous sodium sulfate (Section 7.2.1) into a macro-concentration apparatus (Section 12.6). Rinse the contents of the bottle with two 25 mL portions of hexane and pour through the sodium sulfate into the apparatus.

12.4.2.6 Concentrate the solvent to near dryness using a macro-concentration procedure (Section 12.6).

12.4.2.7 Complete the removal of the solvent using the nitrogen blowdown apparatus (Section 12.7) and a water bath temperature of 60°C. Weigh the receiver, record the weight, and return the receiver to the blowdown apparatus, concentrating the residue until a constant weight is obtained.

- 12.4.2.8 Percent lipid determination—The lipid content is determined in the same solvent system [methylene chloride:hexane (1:1)] that was used in EPA's National Dioxin Study (Reference 22) so that lipid contents are consistent with that study.
- 12.4.2.8.1 Redissolve the residue in the receiver in hexane and spike 1.0 mL of the cleanup standard (Section 7.11) into the solution.
- 12.4.2.8.2 Transfer the residue/hexane to the narrow-mouth 100-200 mL bottle retaining the boiling chips in the receiver. Use several rinses to assure that all material is transferred, to a maximum hexane volume of approximately 70 mL. Allow the receiver to dry. Weigh the receiver and boiling chips.
- 12.4.2.8.3 Calculate the percent lipid per Section 12.4.1.9.3. It is not necessary to determine the lipid content of the blank, IPR, or OPR aliquots.
- 12.4.2.9 Clean up the extract per Section 13.7.3.

12.5 Back-Extraction with Base and Acid

- 12.5.1 Spike 1.0 mL of the cleanup standard (Section 7.11) into the separatory funnels containing the sample and QC extracts from Section 12.1.4.1, 12.3.9.1.3, or 12.3.9.2.
- 12.5.2 Partition the extract against 50 mL of potassium hydroxide solution (Section 7.1.1). Shake for two minutes with periodic venting into a hood. Remove and discard the aqueous layer. Repeat the base washing until no color is visible in the aqueous layer, to a maximum of four washings. Minimize contact time between the extract and the base to prevent degradation of the CDDs/CDFs. Stronger potassium hydroxide solutions may be employed for back-extraction, provided that the laboratory meets the specifications for labeled compound recovery and demonstrates acceptable performance using the procedure in Section 9.2.
- 12.5.3 Partition the extract against 50 mL of sodium chloride solution (Section 7.1.4) in the same way as with base. Discard the aqueous layer.
- 12.5.4 Partition the extract against 50 mL of sulfuric acid (Section 7.1.2) in the same way as with base. Repeat the acid washing until no color is visible in the aqueous layer, to a maximum of four washings.
- 12.5.5 Repeat the partitioning against sodium chloride solution and discard the aqueous layer.
- 12.5.6 Pour each extract through a drying column containing 7-10 cm of granular anhydrous sodium sulfate (Section 7.2.1). Rinse the separatory funnel with 30-50 mL of solvent, and pour through the drying column. Collect each extract in a round-bottom flask. Re-concentrate the sample and QC aliquots per Sections 12.6 through 12.7, and clean up the samples and QC aliquots per Section 13.

12.6 Macro-Concentration—Extracts in toluene are concentrated using a rotary evaporator or a heating mantle; extracts in methylene chloride or hexane are concentrated using a rotary evaporator, heating mantle, or Kuderna-Danish apparatus.

12.6.1 Rotary evaporation—Concentrate the extracts in separate round-bottom flasks.

12.6.1.1 Assemble the rotary evaporator according to manufacturer's instructions, and warm the water bath to 45°C. On a daily basis, preclean the rotary evaporator by concentrating 100 mL of clean extraction solvent through the system. Archive both the concentrated solvent and the solvent in the catch flask for a contamination check if necessary. Between samples, three 2-3 mL aliquots of solvent should be rinsed down the feed tube into a waste beaker.

12.6.1.2 Attach the round-bottom flask containing the sample extract to the rotary evaporator. Slowly apply vacuum to the system, and begin rotating the sample flask.

12.6.1.3 Lower the flask into the water bath, and adjust the speed of rotation and the temperature as required to complete concentration in 15-20 minutes. At the proper rate of concentration, the flow of solvent into the receiving flask will be steady, but no bumping or visible boiling of the extract will occur.

NOTE: *If the rate of concentration is too fast, analyte loss may occur.*

12.6.1.4 When the liquid in the concentration flask has reached an apparent volume of approximately 2 mL, remove the flask from the water bath and stop the rotation. Slowly and carefully admit air into the system. Be sure not to open the valve so quickly that the sample is blown out of the flask. Rinse the feed tube with approximately 2 mL of solvent.

12.6.1.5 Proceed to Section 12.6.4 for preparation for back-extraction or micro-concentration and solvent exchange.

12.6.2 Heating mantle—Concentrate the extracts in separate round-bottom flasks.

12.6.2.1 Add one or two clean boiling chips to the round-bottom flask, and attach a three-ball macro Snyder column. Prewet the column by adding approximately 1 mL of solvent through the top. Place the round-bottom flask in a heating mantle, and apply heat as required to complete the concentration in 15-20 minutes. At the proper rate of distillation, the balls of the column will actively chatter, but the chambers will not flood.

12.6.2.2 When the liquid has reached an apparent volume of approximately 10 mL, remove the round-bottom flask from the heating mantle and allow the solvent to drain and cool for at least 10 minutes.

-
- Remove the Snyder column and rinse the glass joint into the receiver with small portions of solvent.
- 12.6.2.3 Proceed to Section 12.6.4 for preparation for back-extraction or micro-concentration and solvent exchange.
- 12.6.3 Kuderna-Danish (K-D)—Concentrate the extracts in separate 500 mL K-D flasks equipped with 10 mL concentrator tubes. The K-D technique is used for solvents such as methylene chloride and hexane. Toluene is difficult to concentrate using the K-D technique unless a water bath fed by a steam generator is used.
- 12.6.3.1 Add one to two clean boiling chips to the receiver. Attach a three-ball macro Snyder column. Prewet the column by adding approximately 1 mL of solvent through the top. Place the K-D apparatus in a hot water bath so that the entire lower rounded surface of the flask is bathed with steam.
- 12.6.3.2 Adjust the vertical position of the apparatus and the water temperature as required to complete the concentration in 15-20 minutes. At the proper rate of distillation, the balls of the column will actively chatter but the chambers will not flood.
- 12.6.3.3 When the liquid has reached an apparent volume of 1 mL, remove the K-D apparatus from the bath and allow the solvent to drain and cool for at least 10 minutes. Remove the Snyder column and rinse the flask and its lower joint into the concentrator tube with 1-2 mL of solvent. A 5 mL syringe is recommended for this operation.
- 12.6.3.4 Remove the three-ball Snyder column, add a fresh boiling chip, and attach a two-ball micro Snyder column to the concentrator tube. Prewet the column by adding approximately 0.5 mL of solvent through the top. Place the apparatus in the hot water bath.
- 12.6.3.5 Adjust the vertical position and the water temperature as required to complete the concentration in 5-10 minutes. At the proper rate of distillation, the balls of the column will actively chatter but the chambers will not flood.
- 12.6.3.6 When the liquid reaches an apparent volume of 0.5 mL, remove the apparatus from the water bath and allow to drain and cool for at least 10 minutes.
- 12.6.3.7 Proceed to 12.6.4 for preparation for back-extraction or micro-concentration and solvent exchange.
- 12.6.4 Preparation for back-extraction or micro-concentration and solvent exchange.
- 12.6.4.1 For back-extraction (Section 12.5), transfer the extract to a 250 mL separatory funnel. Rinse the concentration vessel with small

portions of hexane, adjust the hexane volume in the separatory funnel to 10-20 mL, and proceed to back-extraction (Section 12.5).

- 12.6.4.2 For determination of the weight of residue in the extract, or for clean-up procedures other than back-extraction, transfer the extract to a blowdown vial using two to three rinses of solvent. Proceed with micro-concentration and solvent exchange (Section 12.7).

12.7 Micro-Concentration and Solvent Exchange

12.7.1 Extracts to be subjected to GPC or HPLC cleanup are exchanged into methylene chloride. Extracts to be cleaned up using silica gel, alumina, carbon, and/or Florisil are exchanged into hexane.

12.7.2 Transfer the vial containing the sample extract to a nitrogen blowdown device. Adjust the flow of nitrogen so that the surface of the solvent is just visibly disturbed.

NOTE: A large vortex in the solvent may cause analyte loss.

12.7.3 Lower the vial into a 45°C water bath and continue concentrating.

12.7.3.1 If the extract is to be concentrated to dryness for weight determination (Sections 12.4.1.8, 12.4.2.7, and 13.7.1.4), blow dry until a constant weight is obtained.

12.7.3.2 If the extract is to be concentrated for injection into the GC/MS or the solvent is to be exchanged for extract cleanup, proceed as follows:

12.7.4 When the volume of the liquid is approximately 100 µL, add 2-3 mL of the desired solvent (methylene chloride for GPC and HPLC, or hexane for the other cleanups) and continue concentration to approximately 100 µL. Repeat the addition of solvent and concentrate once more.

12.7.5 If the extract is to be cleaned up by GPC, adjust the volume of the extract to 5.0 mL with methylene chloride. If the extract is to be cleaned up by HPLC, further concentrate the extract to 30 µL. Proceed with GPC or HPLC cleanup (Section 13.2 or 13.6, respectively).

12.7.6 If the extract is to be cleaned up by column chromatography (alumina, silica gel, Carbopak/Celite, or Florisil), bring the final volume to 1.0 mL with hexane. Proceed with column cleanups (Sections 13.3 through 13.5 and 13.8).

12.7.7 If the extract is to be concentrated for injection into the GC/MS (Section 14), quantitatively transfer the extract to a 0.3 mL conical vial for final concentration, rinsing the larger vial with hexane and adding the rinse to the conical vial. Reduce the volume to approximately 100 µL. Add 10 µL of nonane to the vial, and evaporate the solvent to the level of the nonane. Seal the vial and label with the sample number. Store in the dark at room temperature until ready for

GC/MS analysis. If GC/MS analysis will not be performed on the same day, store the vial at $<-10^{\circ}\text{C}$.

13.0 Extract Cleanup

13.1 Cleanup may not be necessary for relatively clean samples (e.g., treated effluents, groundwater, drinking water). If particular circumstances require the use of a cleanup procedure, the analyst may use any or all of the procedures below or any other appropriate procedure. Before using a cleanup procedure, the analyst must demonstrate that the requirements of Section 9.2 can be met using the cleanup procedure. If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, the cleanup procedures may be optimized for isolation of these two compounds.

13.1.1 Gel permeation chromatography (Section 13.2) removes high molecular weight interferences that cause GC column performance to degrade. It should be used for all soil and sediment extracts and may be used for water extracts that are expected to contain high molecular weight organic compounds (e.g., polymeric materials, humic acids).

13.1.2 Acid, neutral, and basic silica gel (Section 13.3), alumina (Section 13.4), and Florisil (Section 13.8) are used to remove nonpolar and polar interferences. Alumina and Florisil are used to remove chlorodiphenyl ethers.

13.1.3 Caropak/Celite (Section 13.5) is used to remove nonpolar interferences.

13.1.4 HPLC (Section 13.6) is used to provide specificity for the 2,3,7,8-substituted and other CDD and CDF isomers.

13.1.5 The anthropogenic isolation column (Section 13.7.1), acidified silica gel batch adsorption procedure (Section 13.7.2), and sulfuric acid and base back-extraction (Section 13.7.3) are used for removal of lipids from tissue samples.

13.2 Gel Permeation Chromatography (GPC)

13.2.1 Column packing

13.2.1.1 Place 70-75 g of SX-3 Bio-beads (Section 6.7.1.1) in a 400-500 mL beaker.

13.2.1.2 Cover the beads with methylene chloride and allow to swell overnight (a minimum of 12 hours).

13.2.1.3 Transfer the swelled beads to the column (Section 6.7.1.1) and pump solvent through the column, from bottom to top, at 4.5-5.5 mL/minute prior to connecting the column to the detector.

13.2.1.4 After purging the column with solvent for one to two hours, adjust the column head pressure to 7-10 psig and purge for four to five hours to remove air. Maintain a head pressure of 7-10 psig. Connect the column to the detector (Section 6.7.1.4).

13.2.2 Column calibration

- 13.2.2.1 Load 5 mL of the calibration solution (Section 7.4) into the sample loop.
- 13.2.2.2 Inject the calibration solution and record the signal from the detector. The elution pattern will be corn oil, bis(2-ethyl hexyl)phthalate, pentachlorophenol, perylene, and sulfur.
- 13.2.2.3 Set the "dump time" to allow >85% removal of the corn oil and >85% collection of the phthalate.
- 13.2.2.4 Set the "collect time" to the peak minimum between perylene and sulfur.
- 13.2.2.5 Verify the calibration with the calibration solution after every 20 extracts. Calibration is verified if the recovery of the pentachlorophenol is greater than 85%. If calibration is not verified, the system shall be recalibrated using the calibration solution, and the previous 20 samples shall be re-extracted and cleaned up using the calibrated GPC system.

13.2.3 Extract cleanup—GPC requires that the column not be overloaded. The column specified in this method is designed to handle a maximum of 0.5 g of high molecular weight material in a 5 mL extract. If the extract is known or expected to contain more than 0.5 g, the extract is split into aliquots for GPC, and the aliquots are combined after elution from the column. The residue content of the extract may be obtained gravimetrically by evaporating the solvent from a 50 μ L aliquot.

- 13.2.3.1 Filter the extract or load through the filter holder (Section 6.7.1.3) to remove the particles. Load the 5.0 mL extract onto the column.
- 13.2.3.2 Elute the extract using the calibration data determined in Section 13.2.2. Collect the eluate in a clean 400-500 mL beaker.
- 13.2.3.3 Rinse the sample loading tube thoroughly with methylene chloride between extracts to prepare for the next sample.
- 13.2.3.4 If a particularly dirty extract is encountered, a 5.0 mL methylene chloride blank shall be run through the system to check for carry-over.
- 13.2.3.5 Concentrate the eluate per Sections 12.6 and 12.7 for further cleanup or injection into the GC/MS.

13.3 Silica Gel Cleanup

- 13.3.1 Place a glass-wool plug in a 15 mm ID chromatography column (Section 6.7.4.2). Pack the column bottom to top with: 1 g silica gel (Section 7.5.1.1), 4 g basic silica gel (Section 7.5.1.3), 1 g silica gel, 8 g acid silica gel (Section 7.5.1.2), 2 g silica gel,

and 4 g granular anhydrous sodium sulfate (Section 7.2.1). Tap the column to settle the adsorbents.

- 13.3.2 Pre-elute the column with 50-100 mL of hexane. Close the stopcock when the hexane is within 1 mm of the sodium sulfate. Discard the eluate. Check the column for channeling. If channeling is present, discard the column and prepare another.
- 13.3.3 Apply the concentrated extract to the column. Open the stopcock until the extract is within 1 mm of the sodium sulfate.
- 13.3.4 Rinse the receiver twice with 1 mL portions of hexane, and apply separately to the column. Elute the CDDs/CDFs with 100 mL hexane, and collect the eluate.
- 13.3.5 Concentrate the eluate per Sections 12.6 and 12.7 for further cleanup or injection into the HPLC or GC/MS.
- 13.3.6 For extracts of samples known to contain large quantities of other organic compounds (such as paper mill effluents), it may be advisable to increase the capacity of the silica gel column. This may be accomplished by increasing the strengths of the acid and basic silica gels. The acid silica gel (Section 7.5.1.2) may be increased in strength to as much as 44% w/w (7.9 g sulfuric acid added to 10 g silica gel). The basic silica gel (Section 7.5.1.3) may be increased in strength to as much as 33% w/w (50 mL 1N NaOH added to 100 g silica gel), or the potassium silicate (Section 7.5.1.4) may be used.

NOTE: The use of stronger acid silica gel (44% w/w) may lead to charring of organic compounds in some extracts. The charred material may retain some of the analytes and lead to lower recoveries of CDDs/CDFs. Increasing the strengths of the acid and basic silica gel may also require different volumes of hexane than those specified above to elute the analytes off the column. Therefore, the performance of the method after such modifications must be verified by the procedure in Section 9.2.

13.4 Alumina Cleanup

- 13.4.1 Place a glass-wool plug in a 15 mm ID chromatography column (Section 6.7.4.2).
- 13.4.2 If using acid alumina, pack the column by adding 6 g acid alumina (Section 7.5.2.1). If using basic alumina, substitute 6 g basic alumina (Section 7.5.2.2). Tap the column to settle the adsorbents.
- 13.4.3 Pre-elute the column with 50-100 mL of hexane. Close the stopcock when the hexane is within 1 mm of the alumina.
- 13.4.4 Discard the eluate. Check the column for channeling. If channeling is present, discard the column and prepare another.
- 13.4.5 Apply the concentrated extract to the column. Open the stopcock until the extract is within 1 mm of the alumina.

- 13.4.6 Rinse the receiver twice with 1 mL portions of hexane and apply separately to the column. Elute the interfering compounds with 100 mL hexane and discard the eluate.
- 13.4.7 The choice of eluting solvents will depend on the choice of alumina (acid or basic) made in Section 13.4.2.
- 13.4.7.1 If using acid alumina, elute the CDDs/CDFs from the column with 20 mL methylene chloride:hexane (20:80 v/v). Collect the eluate.
- 13.4.7.2 If using basic alumina, elute the CDDs/CDFs from the column with 20 mL methylene chloride:hexane (50:50 v/v). Collect the eluate.
- 13.4.8 Concentrate the eluate per Sections 12.6 and 12.7 for further cleanup or injection into the HPLC or GC/MS.
- 13.5 Carbon Column
- 13.5.1 Cut both ends from a 10 mL disposable serological pipet (Section 6.7.3.2) to produce a 10 cm column. Fire-polish both ends and flare both ends if desired. Insert a glass-wool plug at one end, and pack the column with 0.55 g of Carbowax/Celite (Section 7.5.3.3) to form an adsorbent bed approximately 2 cm long. Insert a glass-wool plug on top of the bed to hold the adsorbent in place.
- 13.5.2 Pre-elute the column with 5 mL of toluene followed by 2 mL of methylene chloride:methanol:toluene (15:4:1 v/v), 1 mL of methylene chloride:cyclohexane (1:1 v/v), and 5 mL of hexane. If the flow rate of eluate exceeds 0.5 mL/minute, discard the column.
- 13.5.3 When the solvent is within 1 mm of the column packing, apply the sample extract to the column. Rinse the sample container twice with 1 mL portions of hexane and apply separately to the column. Apply 2 mL of hexane to complete the transfer.
- 13.5.4 Elute the interfering compounds with two 3 mL portions of hexane, 2 mL of methylene chloride:cyclohexane (1:1 v/v), and 2 mL of methylene chloride:methanol:toluene (15:4:1 v/v). Discard the eluate.
- 13.5.5 Invert the column, and elute the CDDs/CDFs with 20 mL of toluene. If carbon particles are present in the eluate, filter through glass-fiber filter paper.
- 13.5.6 Concentrate the eluate per Sections 12.6 and 12.7 for further cleanup or injection into the HPLC or GC/MS.
- 13.6 HPLC (Reference 6)
- 13.6.1 Column calibration

-
- 13.6.1.1 Prepare a calibration standard containing the 2,3,7,8-substituted isomers and/or other isomers of interest at a concentration of approximately 500 pg/ μ L in methylene chloride.
- 13.6.1.2 Inject 30 μ L of the calibration solution into the HPLC and record the signal from the detector. Collect the eluant for reuse. The elution order will be the tetra- through octa-isomers.
- 13.6.1.3 Establish the collection time for the tetra-isomers and for the other isomers of interest. Following calibration, flush the injection system with copious quantities of methylene chloride, including a minimum of five 50 μ L injections while the detector is monitored, to ensure that residual CDDs/CDFs are removed from the system.
- 13.6.1.4 Verify the calibration with the calibration solution after every 20 extracts. Calibration is verified if the recovery of the CDDs/CDFs from the calibration standard (Section 13.6.1.1) is 75-125% compared to the calibration (Section 13.6.1.2). If calibration is not verified, the system shall be recalibrated using the calibration solution, and the previous 20 samples shall be re-extracted and cleaned up using the calibrated system.
- 13.6.2 Extract cleanup—HPLC requires that the column not be overloaded. The column specified in this method is designed to handle a maximum of 30 μ L of extract. If the extract cannot be concentrated to less than 30 μ L, it is split into fractions and the fractions are combined after elution from the column.
- 13.6.2.1 Rinse the sides of the vial twice with 30 μ L of methylene chloride and reduce to 30 μ L with the evaporation apparatus (Section 12.7).
- 13.6.2.2 Inject the 30 μ L extract into the HPLC.
- 13.6.2.3 Elute the extract using the calibration data determined in Section 13.6.1. Collect the fraction(s) in a clean 20 mL concentrator tube containing 5 mL of hexane:acetone (1:1 v/v).
- 13.6.2.4 If an extract containing greater than 100 ng/mL of total CDD or CDF is encountered, a 30 μ L methylene chloride blank shall be run through the system to check for carry-over.
- 13.6.2.5 Concentrate the eluate per Section 12.7 for injection into the GC/MS.
- 13.7 Cleanup of Tissue Lipids—Lipids are removed from the Soxhlet extract using either the anthropogenic isolation column (Section 13.7.1) or acidified silica gel (Section 13.7.2), or are removed from the HCl digested extract using sulfuric acid and base back-extraction (Section 13.7.3).
- 13.7.1 Anthropogenic isolation column (References 22 and 27)—Used for removal of lipids from the Soxhlet/SDS extraction (Section 12.4.1).

- 13.7.1.1 Prepare the column as given in Section 7.5.4.
- 13.7.1.2 Pre-elute the column with 100 mL of hexane. Drain the hexane layer to the top of the column, but do not expose the sodium sulfate.
- 13.7.1.3 Load the sample and rinses (Section 12.4.1.9.2) onto the column by draining each portion to the top of the bed. Elute the CDDs/CDFs from the column into the apparatus used for concentration (Section 12.4.1.7) using 200 mL of hexane.
- 13.7.1.4 Concentrate the cleaned up extract (Sections 12.6 through 12.7) to constant weight per Section 12.7.3.1. If more than 500 mg of material remains, repeat the cleanup using a fresh anthropogenic isolation column.
- 13.7.1.5 Redissolve the extract in a solvent suitable for the additional cleanups to be used (Sections 13.2 through 13.6 and 13.8).
- 13.7.1.6 Spike 1.0 mL of the cleanup standard (Section 7.11) into the residue/solvent.
- 13.7.1.7 Clean up the extract using the procedures in Sections 13.2 through 13.6 and 13.8. Alumina (Section 13.4) or Florisil (Section 13.8) and carbon (Section 13.5) are recommended as minimum additional cleanup steps.
- 13.7.1.8 Following cleanup, concentrate the extract to 10 μ L as described in Section 12.7 and proceed with the analysis in Section 14.
- 13.7.2 Acidified silica gel (Reference 28)—Procedure alternate to the anthropogenic isolation column (Section 13.7.1) that is used for removal of lipids from the Soxhlet/SDS extraction (Section 12.4.1).
- 13.7.2.1 Adjust the volume of hexane in the bottle (Section 12.4.1.9.2) to approximately 200 mL.
- 13.7.2.2 Spike 1.0 mL of the cleanup standard (Section 7.11) into the residue/solvent.
- 13.7.2.3 Drop the stirring bar into the bottle, place the bottle on the stirring plate, and begin stirring.
- 13.7.2.4 Add 30-100 g of acid silica gel (Section 7.5.1.2) to the bottle while stirring, keeping the silica gel in motion. Stir for two to three hours.

NOTE: 30 grams of silica gel should be adequate for most samples and will minimize contamination from this source.

- 13.7.2.5 After stirring, pour the extract through approximately 10 g of granular anhydrous sodium sulfate (Section 7.2.1) contained in a funnel with glass-fiber filter into a macro concentration device (Section 12.6). Rinse the bottle and sodium sulfate with hexane to complete the transfer.
- 13.7.2.6 Concentrate the extract per Sections 12.6 through 12.7 and clean up the extract using the procedures in Sections 13.2 through 13.6 and 13.8. Alumina (Section 13.4) or Florisil (Section 13.8) and carbon (Section 13.5) are recommended as minimum additional cleanup steps.
- 13.7.3 Sulfuric acid and base back-extraction—Used with HCl digested extracts (Section 12.4.2).
- 13.7.3.1 Spike 1.0 mL of the cleanup standard (Section 7.11) into the residue/solvent (Section 12.4.2.8.2).
- 13.7.3.2 Add 10 mL of concentrated sulfuric acid to the bottle. Immediately cap and shake one to three times. Loosen cap in a hood to vent excess pressure. Cap and shake the bottle so that the residue/solvent is exposed to the acid for a total time of approximately 45 seconds.
- 13.7.3.3 Decant the hexane into a 250 mL separatory funnel making sure that no acid is transferred. Complete the quantitative transfer with several hexane rinses.
- 13.7.3.4 Back extract the solvent/residue with 50 mL of potassium hydroxide solution per Section 12.5.2, followed by two reagent water rinses.
- 13.7.3.5 Drain the extract through a filter funnel containing approximately 10 g of granular anhydrous sodium sulfate in a glass-fiber filter into a macro concentration device (Section 12.6).
- 13.7.3.6 Concentrate the cleaned up extract to a volume suitable for the additional cleanups given in Sections 13.2 through 13.6 and 13.8. Gel permeation chromatography (Section 13.2), alumina (Section 13.4) or Florisil (Section 13.8), and Carbopak/Celite (Section 13.5) are recommended as minimum additional cleanup steps.
- 13.7.3.7 Following cleanup, concentrate the extract to 10 μ L as described in Section 12.7 and proceed with analysis per Section 14.
- 13.8 Florisil Cleanup (Reference 29)
- 13.8.1 Pre-elute the activated Florisil column (Section 7.5.3) with 10 mL of methylene chloride followed by 10 mL of hexane:methylene chloride (98:2 v/v) and discard the solvents.

- 13.8.2 When the solvent is within 1 mm of the packing, apply the sample extract (in hexane) to the column. Rinse the sample container twice with 1 mL portions of hexane and apply to the column.
- 13.8.3 Elute the interfering compounds with 20 mL of hexane:methylene chloride (98:2) and discard the eluate.
- 13.8.4 Elute the CDDs/CDFs with 35 mL of methylene chloride and collect the eluate. Concentrate the eluate per Sections 12.6 through 12.7 for further cleanup or for injection into the HPLC or GC/MS.

14.0 HRGC/HRMS Analysis

- 14.1 Establish the operating conditions given in Section 10.1.
- 14.2 Add 10 μL of the appropriate internal standard solution (Section 7.12) to the sample extract immediately prior to injection to minimize the possibility of loss by evaporation, adsorption, or reaction. If an extract is to be reanalyzed and evaporation has occurred, do not add more instrument internal standard solution. Rather, bring the extract back to its previous volume (e.g., 19 μL) with pure nonane only (18 μL if 2 μL injections are used).
- 14.3 Inject 1.0 μL or 2.0 μL of the concentrated extract containing the internal standard solution, using on-column or splitless injection. The volume injected must be identical to the volume used for calibration (Section 10). Start the GC column initial isothermal hold upon injection. Start MS data collection after the solvent peak elutes. Stop data collection after the OCDD and OCDF have eluted. If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, stop data collection after elution of these compounds. Return the column to the initial temperature for analysis of the next extract or standard.

15.0 System and Laboratory Performance

- 15.1 At the beginning of each 12-hour shift during which analyses are performed, GC/MS system performance and calibration are verified for all CDDs/CDFs and labeled compounds. For these tests, analysis of the CS3 calibration verification (VER) standard (Section 7.13 and Table 4) and the isomer specificity test standards (Section 7.15 and Table 5) shall be used to verify all performance criteria. Adjustment and/or recalibration (Section 10) shall be performed until all performance criteria are met. Only after all performance criteria are met may samples, blanks, IPRs, and OPRs be analyzed.
- 15.2 MS Resolution—A static resolving power of at least 10,000 (10% valley definition) must be demonstrated at the appropriate m/z before any analysis is performed. Static resolving power checks must be performed at the beginning and at the end of each 12-hour shift according to procedures in Section 10.1.2. Corrective actions must be implemented whenever the resolving power does not meet the requirement.
- 15.3 Calibration Verification
- 15.3.1 Inject the VER standard using the procedure in Section 14.

- 15.3.2 The m/z abundance ratios for all CDDs/CDFs shall be within the limits in Table 9; otherwise, the mass spectrometer shall be adjusted until the m/z abundance ratios fall within the limits specified, and the verification test shall be repeated. If the adjustment alters the resolution of the mass spectrometer, resolution shall be verified (Section 10.1.2) prior to repeat of the verification test.
- 15.3.3 The peaks representing each CDD/CDF and labeled compound in the VER standard must be present with S/N of at least 10; otherwise, the mass spectrometer shall be adjusted and the verification test repeated.
- 15.3.4 Compute the concentration of each CDD/CDF compound by isotope dilution (Section 10.5) for those compounds that have labeled analogs (Table 1). Compute the concentration of the labeled compounds by the internal standard method (Section 10.6). These concentrations are computed based on the calibration data in Section 10.
- 15.3.5 For each compound, compare the concentration with the calibration verification limit in Table 6. If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, compare the concentration to the limit in Table 6a. If all compounds meet the acceptance criteria, calibration has been verified and analysis of standards and sample extracts may proceed. If, however, any compound fails its respective limit, the measurement system is not performing properly for that compound. In this event, prepare a fresh calibration standard or correct the problem causing the failure and repeat the resolution (Section 15.2) and verification (Section 15.3) tests, or recalibrate (Section 10).
- 15.4 Retention Times and GC Resolution
- 15.4.1 Retention times
- 15.4.1.1 Absolute—The absolute retention times of the $^{13}\text{C}_{12}$ -1,2,3,4-TCDD and $^{13}\text{C}_{12}$ -1,2,3,7,8,9-HxCDD GCMS internal standards in the verification test (Section 15.3) shall be within ± 15 seconds of the retention times obtained during calibration (Sections 10.2.1 and 10.2.4).
- 15.4.1.2 Relative—The relative retention times of CDDs/CDFs and labeled compounds in the verification test (Section 15.3) shall be within the limits given in Table 2.
- 15.4.2 GC resolution
- 15.4.2.1 Inject the isomer specificity standards (Section 7.15) on their respective columns.
- 15.4.2.2 The valley height between 2,3,7,8-TCDD and the other tetra-dioxin isomers at m/z 319.8965, and between 2,3,7,8-TCDF and the other tetra-furan isomers at m/z 303.9016 shall not exceed 25% on their respective columns (Figures 6 and 7).

- 15.4.3 If the absolute retention time of any compound is not within the limits specified or if the 2,3,7,8-isomers are not resolved, the GC is not performing properly. In this event, adjust the GC and repeat the verification test (Section 15.3) or recalibrate (Section 10), or replace the GC column and either verify calibration or recalibrate.
- 15.5 Ongoing Precision and Recovery
- 15.5.1 Analyze the extract of the ongoing precision and recovery (OPR) aliquot (Section 11.4.2.5, 11.5.4, 11.6.2, 11.7.4, or 11.8.3.2) prior to analysis of samples from the same batch.
- 15.5.2 Compute the concentration of each CDD/CDF by isotope dilution for those compounds that have labeled analogs (Section 10.5). Compute the concentration of 1,2,3,7,8,9-HxCDD, OCDF, and each labeled compound by the internal standard method (Section 10.6).
- 15.5.3 For each CDD/CDF and labeled compound, compare the concentration to the OPR limits given in Table 6. If only 2,3,7,8-TCDD and 2,3,7,8-TCDF are to be determined, compare the concentration to the limits in Table 6a. If all compounds meet the acceptance criteria, system performance is acceptable and analysis of blanks and samples may proceed. If, however, any individual concentration falls outside of the range given, the extraction/concentration processes are not being performed properly for that compound. In this event, correct the problem, re-prepare, extract, and clean up the sample batch and repeat the ongoing precision and recovery test (Section 15.5).
- 15.5.4 Add results that pass the specifications in Section 15.5.3 to initial and previous ongoing data for each compound in each matrix. Update QC charts to form a graphic representation of continued laboratory performance. Develop a statement of laboratory accuracy for each CDD/CDF in each matrix type by calculating the average percent recovery (R) and the standard deviation of percent recovery (S_R). Express the accuracy as a recovery interval from $R-2S_R$ to $R+2S_R$. For example, if $R = 95\%$ and $S_R = 5\%$, the accuracy is 85-105%.
- 15.6 Blank—Analyze the method blank extracted with each sample batch immediately following analysis of the OPR aliquot to demonstrate freedom from contamination and freedom from carryover from the OPR analysis. The results of the analysis of the blank must meet the specifications in Section 9.5.2 before sample analyses may proceed.

16.0 Qualitative Determination

A CDD, CDF, or labeled compound is identified in a standard, blank, or sample when all of the criteria in Sections 16.1 through 16.4 are met.

- 16.1 The signals for the two exact m/z 's in Table 8 must be present and must maximize within the same two seconds.
- 16.2 The signal-to-noise ratio (S/N) for the GC peak at each exact m/z must be greater than or equal to 2.5 for each CDD or CDF detected in a sample extract, and greater than or equal to 10 for all CDDs/CDFs in the calibration standard (Sections 10.2.3 and 15.3.3).

- 16.3 The ratio of the integrated areas of the two exact m/z 's specified in Table 8 must be within the limit in Table 9, or within $\pm 10\%$ of the ratio in the midpoint (CS3) calibration or calibration verification (VER), whichever is most recent.
- 16.4 The relative retention time of the peak for a 2,3,7,8-substituted CDD or CDF must be within the limit in Table 2. The retention time of peaks representing non-2,3,7,8-substituted CDDs/CDFs must be within the retention time windows established in Section 10.3.
- 16.5 Confirmatory Analysis—Isomer specificity for 2,3,7,8-TCDF cannot be achieved on the DB-5 column. Therefore, any sample in which 2,3,7,8-TCDF is identified by analysis on a DB-5 column must have a confirmatory analysis performed on a DB-225, SP-2330, or equivalent GC column. The operating conditions in Section 10.1.1 may be adjusted to optimize the analysis on the second GC column, but the GC/MS must meet the mass resolution and calibration specifications in Section 10.
- 16.6 If the criteria for identification in Sections 16.1 through 16.5 are not met, the CDD or CDF has not been identified and the results may not be reported for regulatory compliance purposes. If interferences preclude identification, a new aliquot of sample must be extracted, further cleaned up, and analyzed.

17.0 Quantitative Determination

- 17.1 Isotope Dilution Quantitation—By adding a known amount of a labeled compound to every sample prior to extraction, correction for recovery of the CDD/CDF can be made because the CDD/CDF and its labeled analog exhibit similar effects upon extraction, concentration, and gas chromatography. Relative response (RR) values are used in conjunction with the initial calibration data described in Section 10.5 to determine concentrations directly, so long as labeled compound spiking levels are constant, using the following equation:

$$C_{ex} \text{ (ng/mL)} = \frac{(A_n + A_n) C_i}{(A_i + A_i) RR}$$

where,

C_{ex} = The concentration of the CDD/CDF in the extract, and the other terms are as defined in Section 10.5.2.

- 17.1.1 Because of a potential interference, the labeled analog of OCDF is not added to the sample. Therefore, OCDF is quantitated against labeled OCDD. As a result, the concentration of OCDF is corrected for the recovery of the labeled OCDD. In instances where OCDD and OCDF behave differently during sample extraction, concentration, and cleanup procedures, this may decrease the accuracy of the OCDF results. However, given the low toxicity of this compound relative to the other dioxins and furans, the potential decrease in accuracy is not considered significant.

17.1.2 Because $^{13}\text{C}_{12}$ -1,2,3,7,8,9-HxCDD is used as an instrument internal standard (i.e., not added before extraction of the sample), it cannot be used to quantitate the 1,2,3,7,8,9-HxCDD by strict isotope dilution procedures. Therefore, 1,2,3,7,8,9-HxCDD is quantitated using the averaged response of the labeled analogs of the other two 2,3,7,8-substituted HxCDD's: 1,2,3,4,7,8-HxCDD and 1,2,3,6,7,8-HxCDD. As a result, the concentration of 1,2,3,7,8,9-HxCDD is corrected for the average recovery of the other two HxCDD's.

17.1.3 Any peaks representing non-2,3,7,8-substituted CDDs/CDFs are quantitated using an average of the response factors from all of the labeled 2,3,7,8-isomers at the same level of chlorination.

17.2 Internal Standard Quantitation and Labeled Compound Recovery

17.2.1 Compute the concentrations of 1,2,3,7,8,9-HxCDD, OCDF, the ^{13}C -labeled analogs and the ^{37}C -labeled cleanup standard in the extract using the response factors determined from the initial calibration data (Section 10.6) and the following equation:

$$C_{ex} \text{ (ng/mL)} = \frac{(A_s + A_{i_s}) C_{is}}{(A_{i_s} + A_{i_s}) RF}$$

where,

C_{ex} = The concentration of the CDD/CDF in the extract, and the other terms are as defined in Section 10.6.1.

NOTE: There is only one m/z for the ^{37}Cl -labeled standard.

17.2.2 Using the concentration in the extract determined above, compute the percent recovery of the ^{13}C -labeled compounds and the ^{37}C -labeled cleanup standard using the following equation:

$$\text{Recovery (\%)} = \frac{\text{Concentration found } (\mu\text{g/mL})}{\text{Concentration spiked } (\mu\text{g/mL})} \times 100$$

17.3 The concentration of a CDD/CDF in the solid phase of the sample is computed using the concentration of the compound in the extract and the weight of the solids (Section 11.5.1), as follows:

$$\text{Concentration in solid (ng/kg)} = \frac{(C_{ex} \times V_{ex})}{W_s}$$

where,

C_{ex} = The concentration of the compound in the extract.

V_{ex} = The extract volume in mL.

W_s = The sample weight (dry weight) in kg.

17.4 The concentration of a CDD/CDF in the aqueous phase of the sample is computed using the concentration of the compound in the extract and the volume of water extracted (Section 11.4 or 11.5), as follows:

$$\text{Concentration in aqueous phase (pg/L)} = \frac{(C_{ex} \times V_{ex})}{V_s}$$

where,

C_{ex} = The concentration of the compound in the extract.

V_{ex} = The extract volume in mL.

V_s = The sample volume in liters.

- 17.5 If the SICP area at either quantitation m/z for any compound exceeds the calibration range of the system, a smaller sample aliquot is extracted.
- 17.5.1 For aqueous samples containing 1% solids or less, dilute 100 mL, 10 mL, etc., of sample to 1 L with reagent water and re-prepare, extract, clean up, and analyze per Sections 11 through 14.
- 17.5.2 For samples containing greater than 1% solids, extract an amount of sample equal to 1/10, 1/100, etc., of the amount used in Section 11.5.1. Re-prepare, extract, clean up, and analyze per Sections 11 through 14.
- 17.5.3 If a smaller sample size will not be representative of the entire sample, dilute the sample extract by a factor of 10, adjust the concentration of the instrument internal standard to 100 pg/ μ L in the extract, and analyze an aliquot of this diluted extract by the internal standard method.
- 17.6 Results are reported to three significant figures for the CDDs/CDFs and labeled compounds found in all standards, blanks, and samples.
- 17.6.1 Reporting units and levels
- 17.6.1.1 Aqueous samples—Report results in pg/L (parts-per-quadrillion).
- 17.6.1.2 Samples containing greater than 1% solids (soils, sediments, filter cake, compost)—Report results in ng/kg based on the dry weight of the sample. Report the percent solids so that the result may be corrected.
- 17.6.1.3 Tissues—Report results in ng/kg of wet tissue, not on the basis of the lipid content of the sample. Report the percent lipid content, so that the data user can calculate the concentration on a lipid basis if desired.
- 17.6.1.4 Reporting level

- 17.6.1.4.1 Standards (VER, IPR, OPR) and samples—Report results at or above the minimum level (Table 2). Report results below the minimum level as not detected or as required by the regulatory authority.
- 17.6.1.4.2 Blanks—Report results above one-third the ML.
- 17.6.2 Results for CDDs/CDFs in samples that have been diluted are reported at the least dilute level at which the areas at the quantitation m/z's are within the calibration range (Section 17.5).
- 17.6.3 For CDDs/CDFs having a labeled analog, results are reported at the least dilute level at which the area at the quantitation m/z is within the calibration range (Section 17.5) and the labeled compound recovery is within the normal range for the method (Section 9.3 and Tables 6, 6a, 7, and 7a).
- 17.6.4 Additionally, if requested, the total concentration of all isomers in an individual level of chlorination (i.e., total TCDD, total TCDF, total Paced, etc.) may be reported by summing the concentrations of all isomers identified in that level of chlorination, including both 2,3,7,8-substituted and non-2,3,7,8-substituted isomers.

18.0 Analysis of Complex Samples

- 18.1 Some samples may contain high levels (>10 ng/L; >1000 ng/kg) of the compounds of interest, interfering compounds, and/or polymeric materials. Some extracts will not concentrate to 10 μ L (Section 12.7); others may overload the GC column and/or mass spectrometer.
- 18.2 Analyze a smaller aliquot of the sample (Section 17.5) when the extract will not concentrate to 10 μ L after all cleanup procedures have been exhausted.
- 18.3 Chlorodiphenyl Ethers—If chromatographic peaks are detected at the retention time of any CDDs/CDFs in any of the m/z channels being monitored for the chlorodiphenyl ethers (Table 8), cleanup procedures must be employed until these interferences are removed. Alumina (Section 13.4) and Florisil (Section 13.8) are recommended for removal of chlorodiphenyl ethers.
- 18.4 Recovery of Labeled Compounds—In most samples, recoveries of the labeled compounds will be similar to those from reagent water or from the alternate matrix (Section 7.6).
- 18.4.1 If the recovery of any of the labeled compounds is outside of the normal range (Table 7), a diluted sample shall be analyzed (Section 17.5).
- 18.4.2 If the recovery of any of the labeled compounds in the diluted sample is outside of normal range, the calibration verification standard (Section 7.13) shall be analyzed and calibration verified (Section 15.3).
- 18.4.3 If the calibration cannot be verified, a new calibration must be performed and the original sample extract reanalyzed.

18.4.4 If the calibration is verified and the diluted sample does not meet the limits for labeled compound recovery, the method does not apply to the sample being analyzed and the result may not be reported for regulatory compliance purposes. In this case, alternate extraction and cleanup procedures in this method must be employed to resolve the interference. If all cleanup procedures in this method have been employed and labeled compound recovery remains outside of the normal range, extraction and/or cleanup procedures that are beyond this scope of this method will be required to analyze these samples.

19.0 Pollution Prevention

- 19.1 The solvents used in this method pose little threat to the environment when managed properly. The solvent evaporation techniques used in this method are amenable to solvent recovery, and it is recommended that the laboratory recover solvents wherever feasible.
- 19.2 Standards should be prepared in volumes consistent with laboratory use to minimize disposal of standards.

20.0 Waste Management

- 20.1 It is the laboratory's responsibility to comply with all federal, state, and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions, and to protect the air, water, and land by minimizing and controlling all releases from fume hoods and bench operations. Compliance is also required with any sewage discharge permits and regulations.
- 20.2 Samples containing HCl to pH <2 are hazardous and must be neutralized before being poured down a drain or must be handled as hazardous waste.
- 20.3 The CDDs/CDFs decompose above 800°C. Low-level waste such as absorbent paper, tissues, animal remains, and plastic gloves may be burned in an appropriate incinerator. Gross quantities (milligrams) should be packaged securely and disposed of through commercial or governmental channels that are capable of handling extremely toxic wastes.
- 20.4 Liquid or soluble waste should be dissolved in methanol or ethanol and irradiated with ultraviolet light with a wavelength shorter than 290 nm for several days. Use F40 BL or equivalent lamps. Analyze liquid wastes, and dispose of the solutions when the CDDs/CDFs can no longer be detected.
- 20.5 For further information on waste management, consult "The Waste Management Manual for Laboratory Personnel" and "Less is Better—Laboratory Chemical Management for Waste Reduction," available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th Street N.W., Washington, D.C. 20036.

21.0 Method Performance

Method performance was validated and performance specifications were developed using data from EPA's international interlaboratory validation study (References 30-31) and the

EPA/paper industry Long-Term Variability Study of discharges from the pulp and paper industry (58 FR 66078).

¹³ C ₁₂ -OCDD	¹³ C ₁₂ -1,2,3,7,8,9-HxCDD	1.032–1.311			

¹The Minimum Level (ML) for each analyte is defined as the level at which the entire analytical system must give a recognizable signal and acceptable calibration point. It is equivalent to the concentration of the lowest calibration standard, assuming that all method-specified sample weights, volumes, and cleanup procedures have been employed.

²The retention time reference for 1,2,3,7,8,9-HxCDD is ¹³C₁₂-1,2,3,6,7,8-HxCDD, and 1,2,3,7,8,9-HxCDD is quantified using the averaged responses for ¹³C₁₂-1,2,3,4,7,8-HxCDD and ¹³C₁₂-1,2,3,6,7,8-HxCDD.

TABLE 3. CONCENTRATION OF STOCK AND SPIKING SOLUTIONS CONTAINING CDDS/CDFS AND LABELED COMPOUNDS

CDD/CDF	Labeled Compound Stock Solution ¹ (ng/mL)	Labeled Compound Spiking Solution ² (ng/mL)	PAR Stock Solution ³ (ng/mL)	PAR Spiking Solution ⁴ (ng/mL)

7 ⁴	M/(M+2)	0.44	0.37	0.51
8	(M+2)/(M+4)	0.89	0.76	1.02

¹ QC limits represent $\pm 15\%$ windows around the theoretical ion abundance ratios.

² Does not apply to ³⁷Cl₄-2,3,7,8-TCDD (cleanup standard).

³ Used for ¹³C₁₂-HxCDF only.

⁴ Used for ¹³C₁₂-HpCDF only.

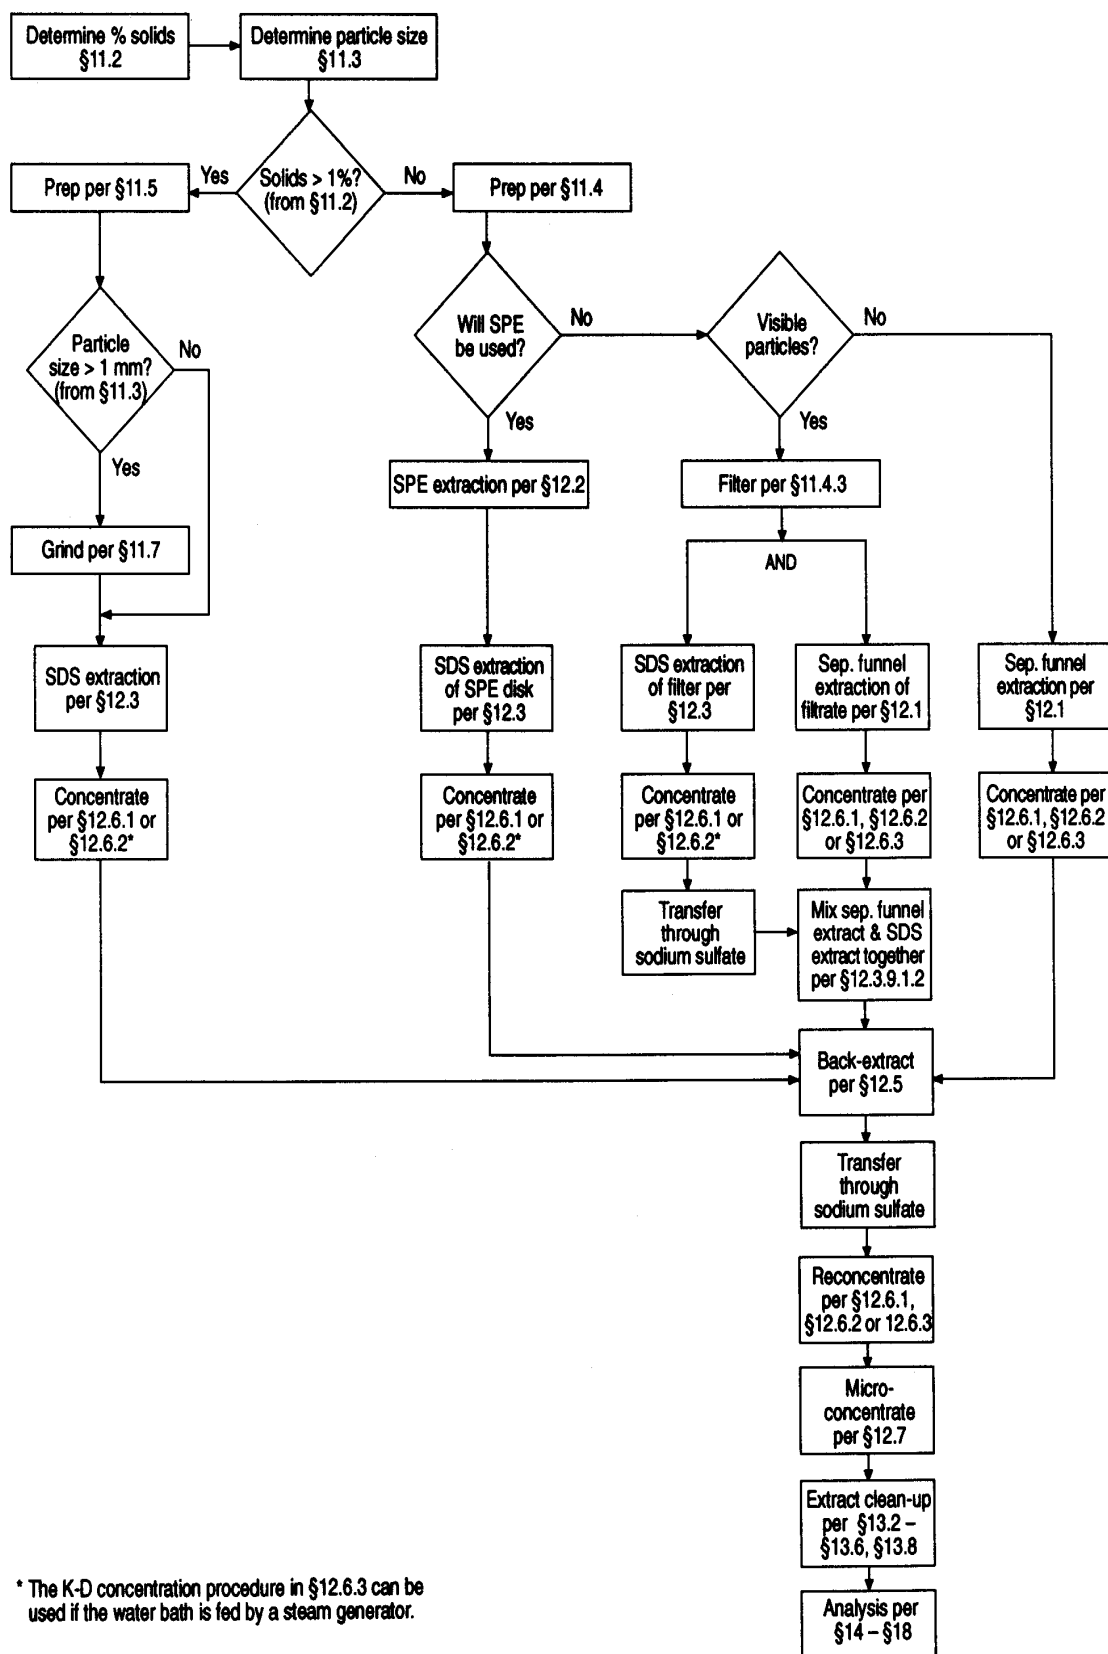

TABLE 10. SUGGESTED SAMPLE QUANTITIES TO BE EXTRACTED FOR VARIOUS MATRICES ¹

Sample Matrix ²	Example	Percent Solids	Phase	Quantity Extracted
Single-phase				
Aqueous	Drinking water Groundwater Treated wastewater	<1	— ³	1000 mL
Solid	Dry soil Compost Ash	>20	Solid	10 g
Organic	Waste solvent Waste oil Organic polymer	<1	Organic	10 g
Tissue	Fish Human adipose	—	Organic	10 g
Multi-phase				
Liquid/Solid				
Aqueous/Solid	Wet soil Untreated effluent Digested municipal sludge Filter cake Paper pulp	1–30	Solid	10 g
Organic/solid	Industrial sludge Oily waste	1–100	Both	10 g
Liquid/Liquid				
Aqueous/organic	In-process effluent Untreated effluent Drum waste	<1	Organic	10 g
Aqueous/organic/solid	Untreated effluent Drum waste	>1	Organic & solid	10 g

¹ The quantity of sample to be extracted is adjusted to provide 10 g of solids (dry weight). One liter of aqueous samples containing 1% solids will contain 10 g of solids. For aqueous samples containing greater than 1% solids, a lesser volume is used so that 10 g of solids (dry weight) will be extracted.

² The sample matrix may be amorphous for some samples. In general, when the CDDs/CDFs are in contact with a multiphase system in which one of the phases is water, they will be preferentially dispersed in or adsorbed on the alternate phase because of their low solubility in water.

³ Aqueous samples are filtered after spiking with the labeled compounds. The filtrate and the materials trapped on the filter are extracted separately, and the extracts are combined for cleanup and analysis.

24.0 Glossary of Definitions and Purposes

These definitions and purposes are specific to this method but have been conformed to common usage as much as possible.

24.1 Units of weight and Measure and Their Abbreviations

24.1.1 Symbols

°C	degrees Celsius
μL	microliter
μm	micrometer
<	less than
>	greater than
%	percent

24.1.2 Alphabetical abbreviations

amp	ampere
cm	centimeter
g	gram
h	hour
ID	inside diameter
in.	inch
L	liter
M	Molecular ion
m	meter
mg	milligram
min	minute
mL	milliliter
mm	millimeter
m/z	mass-to-charge ratio
N	normal; gram molecular weight of solute divided by hydrogen equivalent of solute, per liter of solution
OD	outside diameter
pg	picogram
ppb	part-per-billion
ppm	part-per-million
ppq	part-per-quadrillion
ppt	part-per-trillion
psig	pounds-per-square inch gauge
v/v	volume per unit volume
w/v	weight per unit volume

24.2 Definitions and Acronyms (in Alphabetical Order)

Analyte—A CDD or CDF tested for by this method. The analytes are listed in Table 1.

Calibration Standard (CAL)—A solution prepared from a secondary standard and/or stock solutions and used to calibrate the response of the instrument with respect to analyte concentration.

Calibration Verification Standard (VER)—The mid-point calibration standard (CS3) that is used in to verify calibration. See Table 4.

CDD—Chlorinated Dibenzo-*p*-ioxin—The isomers and congeners of tetra- through octa-chlorodibenzo-*p*-dioxin.

CDF—Chlorinated Dibenzofuran—The isomers and congeners of tetra- through octa-chlorodibenzofuran.

CS1, CS2, CS3, CS4, CS5—See Calibration standards and Table 4.

Field Blank—An aliquot of reagent water or other reference matrix that is placed in a sample container in the laboratory or the field, and treated as a sample in all respects, including exposure to sampling site conditions, storage, preservation, and all analytical procedures. The purpose of the field blank is to determine if the field or sample transporting procedures and environments have contaminated the sample.

GC—Gas chromatograph or gas chromatography.

GPC—Gel permeation chromatograph or gel permeation chromatography.

HPLC—High performance liquid chromatograph or high performance liquid chromatography.

HRGC—High resolution GC.

HRMS—High resolution MS.

IPR—Initial precision and recovery; four aliquots of the diluted PAR standard analyzed to establish the ability to generate acceptable precision and accuracy. An IPR is performed prior to the first time this method is used and any time the method or instrumentation is modified.

K-D—Kuderna-Danish concentrator; a device used to concentrate the analytes in a solvent.

Laboratory Blank—See method blank.

Laboratory Control sample (LCS)—See ongoing precision and recovery standard (OPR).

Laboratory Reagent Blank—See method blank.

May—This action, activity, or procedural step is neither required nor prohibited.

May Not—This action, activity, or procedural step is prohibited.

Method Blank—An aliquot of reagent water that is treated exactly as a sample including exposure to all glassware, equipment, solvents, reagents, internal standards, and surrogates that are used with samples. The method blank is used to determine if analytes or interferences are present in the laboratory environment, the reagents, or the apparatus.

Minimum Level (ML)—The level at which the entire analytical system must give a recognizable signal and acceptable calibration point for the analyte. It is equivalent to the concentration of the lowest calibration standard, assuming that all method-specified sample weights, volumes, and cleanup procedures have been employed.

MS—Mass spectrometer or mass spectrometry.

Must—This action, activity, or procedural step is required.

OPR—Ongoing precision and recovery standard (OPR); a laboratory blank spiked with known quantities of analytes. The OPR is analyzed exactly like a sample. Its purpose is to assure that the results produced by the laboratory remain within the limits specified in this method for precision and recovery.

PAR—Precision and recovery standard; secondary standard that is diluted and spiked to form the IPR and OPR.

PFK—Perfluorokerosene; the mixture of compounds used to calibrate the exact m/z scale in the HRMS.

Preparation Blank—See method blank.

Primary Dilution Standard—A solution containing the specified analytes that is purchased or prepared from stock solutions and diluted as needed to prepare calibration solutions and other solutions.

Quality Control Check Sample (QCS)—A sample containing all or a subset of the analytes at known concentrations. The QCS is obtained from a source external to the laboratory or is prepared from a source of standards different from the source of calibration standards. It is used to check laboratory performance with test materials prepared external to the normal preparation process.

Reagent Water—Water demonstrated to be free from the analytes of interest and potentially interfering substances at the method detection limit for the analyte.

Relative Standard Deviation (RSD)—The standard deviation times 100 divided by the mean. Also termed "coefficient of variation."

RF—Response factor. See Section 10.6.1.

RR—Relative response. See Section 10.5.2.

RSD—See relative standard deviation.

SDS—Soxhlet/Dean-Stark extractor; an extraction device applied to the extraction of solid and semi-solid materials (Reference 7).

Should—This action, activity, or procedural step is suggested but not required.

SICP—Selected ion current profile; the line described by the signal at an exact m/z .

SPE—Solid-phase extraction; an extraction technique in which an analyte is extracted from an aqueous sample by passage over or through a material capable of reversibly adsorbing the analyte. Also termed liquid-solid extraction.

Stock Solution—A solution containing an analyte that is prepared using a reference material traceable to EPA, the National Institute of Science and Technology (NIST), or a source that will attest to the purity and authenticity of the reference material.

TCDD—Tetrachlorodibenzo-*p*-dioxin.

TCDF—Tetrachlorodibenzofuran.

VER—See calibration verification standard.

Method 1668, Revision A

Chlorinated Biphenyl Congeners in Water, Soil, Sediment, Biosolids, and Tissue by HRGC/HRMS

With corrections and changes through August 20, 2003

Introduction

Method 1668A, with corrections and changes through August 20, 2003, was developed by the Office of Water's Office of Science and Technology (OST) to determine chlorinated biphenyl congeners in environmental samples by isotope dilution and internal standard high resolution gas chromatography/high resolution mass spectrometry (HRGC/HRMS). This method is applicable to aqueous, solid, tissue, and multi-phase matrices.

Acknowledgments

This method was prepared under EPA contract by Interface, Inc. and DynCorp Environmental. EPA acknowledges the analysts and laboratories that contributed corrections and suggested improvements. Data for this version were provided by Axys Analytical Services, Ltd., Sidney, BC, Canada.

Disclaimer

This method has been reviewed by the Engineering and Analytical Support Branch of the Engineering and Analysis Division (EAD) in OST. The method is available for general use, but has not been published in 40 CFR Part 136. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

Method 1668, Revision A [with corrections and changes through 8/20/03]

Chlorinated Biphenyl Congeners in Water, Soil, Sediment, Biosolids and Tissue by HRGC/HRMS

1.0 Scope and application

- 1.1** Method 1668, Revision A (Method 1668A; the Method) is for determination of chlorinated biphenyl congeners (CBs) in water, soil, sediment, biosolids, tissue, and other sample matrices by high resolution gas chromatography/high resolution mass spectrometry (HRGC/HRMS).
- 1.1.1** The CBs that can be determined by this Method are the 12 polychlorinated biphenyls (PCBs) designated as toxic by the World Health Organization (WHO) plus the remaining 197 CBs, approximately 125 of which are resolved adequately on an SPB-octyl gas chromatographic column to be determined as individual congeners. The remaining approximately 70 congeners are determined as mixtures of isomers (co-elutions).
- 1.1.2** The 12 PCBs designated as toxic by WHO (Toxics; also known as dioxin-like PCBs; DLPCBs) and the earliest and latest eluted congener at each level of chlorination (LOC CBs) are determined by the isotope dilution quantitation technique; the remaining congeners are determined by the internal standard quantitation technique.
- 1.1.3** This Method allows determination of the PCB toxicity equivalent (TEQ_{PCB}) for the Toxics in a sample using toxicity equivalency factors (TEFs; Reference 1) and allows unique determination of 19 of 21 CBs of interest to the National Oceanic and Atmospheric Administration (NOAA; Reference 2). A second-column option is provided for resolution of the two toxic PCB congeners (with congener numbers 156 and 157) that are not resolved on the SPB-octyl column and for resolution of other CB congeners.
- 1.1.4** This Method also allows estimation of homolog totals by level of chlorination (LOC) and estimation of total CBs in a sample by summation of the concentrations of the CB congeners and congener groups.
- 1.1.5** The list of 209 CBs is given in Table 1 with the Toxics, the CBs of interest to NOAA, and the LOC CBs identified.
- 1.2** This Method is for use in data gathering and monitoring associated with the Clean Water Act, the Resource Conservation and Recovery Act, the Comprehensive Environmental Response, Compensation and Liability Act, and the Safe Drinking Water Act. It is based on a compilation of methods from the technical literature (References 3-5) and on EPA Method 1613.
- 1.3** The detection limits and quantitation levels in this Method are usually dependent on the level of interferences and laboratory background levels rather than instrumental limitations. The estimated minimum levels of quantitation (EMLs) in Table 2 are the levels at which the CBs can be determined with laboratory contamination present. The estimated method detection

limit (EMDL) for CB 126 in water is 5 pg/L (picograms-per-liter; parts-per-quadrillion) with no interferences present.

- 1.4** The GC/MS portions of this Method are for use only by analysts experienced with HRGC/HRMS or under the close supervision of such qualified persons. Each laboratory that uses this Method must demonstrate the ability to generate acceptable results using the procedure in Section 9.2.
- 1.5** This Method is "performance-based." The laboratory is permitted to modify the Method to overcome interferences or lower the cost of measurements, provided that all performance criteria are met. The requirements for establishing Method equivalency are given in Section 9.1.2.
- 1.6** Any modification of this Method, beyond those expressly permitted, shall be considered a major modification subject to application and approval of alternate test procedures under 40 CFR 136.4 and 136.5.

2.0 Summary of method

Flow charts that summarize procedures for sample preparation, extraction, and analysis are given in Figure 1 for aqueous and solid samples, Figure 2 for multi-phase samples, and Figure 3 for tissue samples.

2.1 Extraction

- 2.1.1** Aqueous samples (samples containing less than one percent solids)—Stable isotopically labeled analogs of the Toxics and labeled LOC CBs are spiked into a 1-L sample. The sample is extracted using solid-phase extraction (SPE), separatory funnel extraction (SFE), or continuous liquid/liquid extraction (CLLE).
 - 2.1.2** Solid, semi-solid, and multi-phase samples (excluding tissue)—The labeled compounds are spiked into a sample containing 10 g (dry weight) of solids. Samples containing multiple phases are pressure filtered and any aqueous liquid is discarded. Coarse solids are ground or homogenized. Any non-aqueous liquid from multi-phase samples is combined with the solids and extracted in a Soxhlet/Dean-Stark (SDS) extractor. The extract is concentrated for cleanup.
 - 2.1.3** Fish and other tissue—A 20-g aliquot of sample is homogenized, and a 10-g aliquot is spiked with the labeled compounds. The sample is mixed with anhydrous sodium sulfate, allowed to dry for 12 - 24 hours, and extracted for 18-24 hours using methylene chloride in a Soxhlet extractor. The extract is evaporated to dryness, and the lipid content is determined.
- 2.2** After extraction, a labeled cleanup standard is spiked into the extract which is then cleaned up using back-extraction with sulfuric acid and/or base, and gel permeation, silica gel, or Florisil chromatography. Activated carbon and high-performance liquid chromatography (HPLC) can be used for further isolation of specific congener groups. Prior to the cleanup procedures cited above, tissue extracts are cleaned up using an anthropogenic isolation column.

- 2.3** After cleanup, the extract is concentrated to 20 μL . Immediately prior to injection, labeled injection internal standards are added to each extract and an aliquot of the extract is injected into the gas chromatograph (GC). The analytes are separated by the GC and detected by a high-resolution ($\geq 10,000$) mass spectrometer. Two exact m/z 's are monitored at each level of chlorination (LOC) throughout a pre-determined retention time window.
- 2.4** An individual CB congener is identified by comparing the GC retention time and ion-abundance ratio of two exact m/z 's with the corresponding retention time of an authentic standard and the theoretical or acquired ion-abundance ratio of the two exact m/z 's. Isomer specificity for certain of the CB congeners is achieved using GC columns that resolve these congeners.
- 2.5** Quantitative analysis is performed in one of two ways using selected ion current profile (SICP) areas:
- 2.5.1** For the Toxics and the LOC CBs, the GC/MS is multi-point calibrated and the concentration is determined using the isotope dilution technique.
- 2.5.2** For all congeners other than the Toxics and LOC CBs, the GC/MS is calibrated at a single concentration and the concentrations are determined using the internal standard technique.
- 2.5.3** For the labeled Toxics, labeled LOC CBs, and the cleanup standards, the GC/MS is calibrated using replicates at a single concentration and the concentrations of these labeled compounds in samples are determined using the internal standard technique.
- 2.6** The quality of the analysis is assured through reproducible calibration and testing of the extraction, cleanup, and GC/MS systems.

3.0 Definitions

Definitions are given in the glossary at the end of this Method.

4.0 Contamination and interferences

- 4.1** Solvents, reagents, glassware, and other sample processing hardware may yield artifacts, elevated baselines, and/or lock-mass suppression causing misinterpretation of chromatograms. Specific selection of reagents and purification of solvents by distillation in all-glass systems may be required. Where possible, reagents are cleaned by extraction or solvent rinse. Environmentally abundant CBs, as well as toxic congeners 105, 114, 118, 123, 156, 157, and 167 have been shown to be very difficult to completely eliminate from the laboratory at levels lower than the EMDLs in this Method (Table 2), and baking of glassware in a kiln or furnace at 450 - 500 $^{\circ}\text{C}$ may be necessary to remove these and other contaminants.
- 4.2** Proper cleaning of glassware is extremely important, because glassware may not only contaminate the samples but may also remove the analytes of interest by adsorption on the glass surface.

- 4.2.1** Glassware should be rinsed with solvent and washed with a detergent solution as soon after use as is practical. Sonication of glassware containing a detergent solution for approximately 30 seconds may aid in cleaning. Glassware with removable parts, particularly separatory funnels with fluoropolymer stopcocks, must be disassembled prior to detergent washing.
- 4.2.2** After detergent washing, glassware should be rinsed immediately, first with methanol, then with hot tap water. The tap water rinse is followed by another methanol rinse, then acetone, and then methylene chloride.
- 4.2.3** Baking of glassware in a kiln or other high temperature furnace (300 - 500 °C) may be warranted after particularly dirty samples are encountered. The kiln or furnace should be vented to prevent laboratory contamination by CB vapors. Baking should be minimized, as repeated baking of glassware may cause active sites on the glass surface that may irreversibly adsorb CBs.
- 4.2.4** Immediately prior to use, the Soxhlet apparatus should be pre-extracted with toluene for approximately 3 hours (see Sections 12.3.1-12.3.3). The extraction apparatus (Section 6.4) should be rinsed with methylene chloride/toluene (80/20 mixture).
- 4.2.5** A separate set of glassware may be necessary to effectively preclude contamination when low-level samples are analyzed.
- 4.3** All materials used in the analysis must be demonstrated to be free from interferences by running reference matrix method blanks (Section 9.5) initially and with each sample batch (samples started through the extraction process on a given 12-hour shift, to a maximum of 20 samples).
- 4.3.1** The reference matrix must simulate, as closely as possible, the sample matrix under test. Ideally, the reference matrix should not contain the CBs in detectable amounts, but should contain potential interferents in the concentrations expected to be found in the samples to be analyzed.
- 4.3.2** When a reference matrix that simulates the sample matrix under test is not available, reagent water (Section 7.6.1) can be used to simulate water samples; playground sand (Section 7.6.2) or white quartz sand (Section 7.3.2) can be used to simulate soils; filter paper (Section 7.6.3) can be used to simulate papers and similar materials; and corn oil (Section 7.6.4) can be used to simulate tissues.
- 4.4** Interferences co-extracted from samples will vary considerably from source to source, depending on the diversity of the site being sampled. Interfering compounds may be present at concentrations several orders of magnitude higher than the CBs. The most frequently encountered interferences are chlorinated dioxins and dibenzofurans, methoxy biphenyls, hydroxydiphenyl ethers, benzylphenyl ethers, brominated diphenyl ethers, polynuclear aromatics, polychlorinated naphthalenes, and pesticides. Because very low levels of CBs are measured by this Method, the elimination of interferences is essential. The cleanup steps given in Section 13 can be used to reduce or eliminate these interferences and thereby permit reliable determination of the CBs at the levels shown in Table 2.

- 4.5** Each piece of reusable glassware should be numbered to associate that glassware with the processing of a particular sample. This will assist the laboratory in tracking possible sources of contamination for individual samples, identifying glassware associated with highly contaminated samples that may require extra cleaning, and determining when glassware should be discarded.
- 4.6** Contamination of calibration solutions—The EMDLs and EMLs in Table 2 are the levels that can be achieved with normal laboratory backgrounds present. Many of the EMLs are greater than the equivalent concentrations of the calibration solutions. In order to prevent contamination of the calibration solutions with the backgrounds allowed by the EMLs, the calibration solutions must be prepared in an area free from CB contamination using glassware free from contamination. If these requirements cannot be met or are difficult to meet in the laboratory, the laboratory should prepare the calibration solutions in a contamination-free facility or have a vendor prepare the calibration standards and guarantee freedom from contamination.
- 4.7** Cleanup of tissue—The natural lipid content of tissue can interfere in the analysis of tissue samples for the CBs. The lipid contents of different species and portions of tissue can vary widely. Lipids are soluble to varying degrees in various organic solvents and may be present in sufficient quantity to overwhelm the column chromatographic cleanup procedures used for cleanup of sample extracts. Lipids must be removed by the anthropogenic isolation column procedure in Section 13.6, followed by the gel permeation chromatography procedure in Section 13.2. Florisil (Section 13.7) is recommended as an additional cleanup step.
- 4.8** If the laboratory air is a potential source of CB contamination, samples, reagents, glassware, and other materials should be dried in a glove box or other area free from contamination.

5.0 Safety

- 5.1** The toxicity or carcinogenicity of each chemical used in this Method has not been precisely determined; however, each compound should be treated as a potential health hazard. Exposure to these compounds should be reduced to the lowest possible level.
- 5.1.1** PCBs have been tentatively classified as known or suspected human or mammalian carcinogens. On the basis of the available toxicological and physical properties of the CBs, pure standards should be handled only by highly trained personnel thoroughly familiar with handling and cautionary procedures and the associated risks.
- 5.1.2** It is recommended that the laboratory purchase dilute standard solutions of the analytes in this Method. However, if primary solutions are prepared, they must be prepared in a hood, and a NIOSH/MESA approved toxic gas respirator must be worn when high concentrations are handled.
- 5.2** The laboratory is responsible for maintaining a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this Method. A reference file of material safety data sheets (MSDSs) should also be made available to all personnel involved in these analyses. It is also suggested that the laboratory perform personal hygiene monitoring of each analyst who uses this Method and that the results of this monitoring be made available to the analyst. Additional information on laboratory safety can be found in References 6-9. The

references and bibliography at the end of Reference 8 are particularly comprehensive in dealing with the general subject of laboratory safety.

5.3 The pure CBs and samples suspected to contain these compounds are handled using essentially the same techniques employed in handling radioactive or infectious materials. Well-ventilated, controlled access laboratories are required. Assistance in evaluating the health hazards of particular laboratory conditions may be obtained from certain consulting laboratories and from State Departments of Health or Labor, many of which have an industrial health service. Each laboratory must develop a strict safety program for handling these compounds. The practices in Reference 10 for handling chlorinated dibenzo-*p*-dioxins and dibenzofurans (CDDs/CDFs) are also recommended for handling the CBs.

5.3.1 Facility—When finely divided samples (dusts, soils, dry chemicals) are handled, all operations (including removal of samples from sample containers, weighing, transferring, and mixing) should be performed in a glove box demonstrated to be leak tight or in a fume hood demonstrated to have adequate air flow. Gross losses to the laboratory ventilation system must not be allowed. Handling of the dilute solutions normally used in analytical and animal work presents no inhalation hazards except in the case of an accident.

5.3.2 Protective equipment—Disposable plastic gloves, apron or lab coat, safety glasses or mask, and a glove box or fume hood adequate for radioactive work should be used. During analytical operations that may give rise to aerosols or dusts, personnel should wear respirators equipped with activated carbon filters. Eye protection (preferably full face shields) must be worn while working with exposed samples or pure analytical standards. Latex gloves are commonly used to reduce exposure of the hands. When handling samples suspected or known to contain high concentrations of the CBs, an additional set of gloves can also be worn beneath the latex gloves.

5.3.3 Training—Workers must be trained in the proper method of removing contaminated gloves and clothing without contacting the exterior surfaces.

5.3.4 Personal hygiene—Hands and forearms should be washed thoroughly after each manipulation and before breaks (coffee, lunch, and shift).

5.3.5 Confinement—Isolated work areas posted with signs, segregated glassware and tools, and plastic absorbent paper on bench tops will aid in confining contamination.

5.3.6 Effluent vapors—The effluent of the sample splitter from the gas chromatograph (GC) and from roughing pumps on the mass spectrometer (MS) should pass through either a column of activated charcoal or be bubbled through a trap containing oil or high-boiling alcohols to condense CB vapors.

5.3.7 Waste Handling—Good technique includes minimizing contaminated waste. Plastic bag liners should be used in waste cans. Janitors and other personnel should be trained in the safe handling of waste.

5.3.8 Decontamination

5.3.8.1 Decontamination of personnel—Use any mild soap with plenty of scrubbing action.

5.3.8.2 Glassware, tools, and surfaces—Chlorothene NU Solvent is a less toxic solvent that should be effective in removing CBs. Satisfactory cleaning may be accomplished by rinsing with Chlorothene, then washing with any detergent and water. If glassware is first rinsed with solvent, the wash water may be disposed of in the sewer. Given the cost of disposal, it is prudent to minimize solvent wastes.

5.3.9 Laundry—Clothing known to be contaminated should be collected in plastic bags. Persons that convey the bags and launder the clothing should be advised of the hazard and trained in proper handling. The clothing may be put into a washer without contact if the launderer knows of the potential problem. The washer should be run through a cycle before being used again for other clothing.

5.3.10 Wipe tests—A useful method of determining cleanliness of work surfaces and tools is to perform a wipe test of the surface suspected of being contaminated.

5.3.10.1 Using a piece of filter paper moistened with Chlorothene or other solvent, wipe an area approximately 10 x 10 cm.

5.3.10.2 Extract and analyze the wipe by GC with an electron capture detector (ECD) or by this Method.

5.3.10.2 Using the area wiped (e.g., 10 x 10 cm = 0.01 m²), calculate the concentration in µg/m². A concentration less than 1 µg/m² indicates acceptable cleanliness; anything higher warrants further cleaning. More than 100 µg/m² constitutes an acute hazard and requires prompt cleaning before further use of the equipment or work space, and indicates that unacceptable work practices have been employed.

6.0 Apparatus and materials

Note: Brand names, suppliers, and part numbers are for illustration purposes only and no endorsement is implied. Equivalent performance may be achieved using apparatus and materials other than those specified here. Meeting the performance requirements of this Method is the responsibility of the laboratory.

6.1 Sampling equipment for discrete or composite sampling

6.1.1 Sample bottles and caps

6.1.1.1 Liquid samples (waters, sludges and similar materials containing 5 percent solids or less)—Sample bottle, amber glass, 1.1-L minimum, with screw cap.

- 6.1.1.2** Solid samples (soils, sediments, sludges, paper pulps, filter cake, compost, and similar materials that contain more than 5 percent solids)—Sample bottle, wide mouth, amber glass, 500-mL minimum.
- 6.1.1.3** If amber bottles are not available, samples must be protected from light.
- 6.1.1.4** Bottle caps—Threaded to fit sample bottles. Caps must be lined with fluoropolymer.
- 6.1.1.5** Cleaning
 - 6.1.1.5.1** Bottles are detergent water washed, then solvent rinsed before use.
 - 6.1.1.5.2** Liners are detergent water washed and rinsed with reagent water (Section 7.6.1).
- 6.1.2** Compositing equipment—Automatic or manual compositing system incorporating glass containers cleaned per bottle cleaning procedure above. Only glass or fluoropolymer tubing must be used. If the sampler uses a peristaltic pump, a minimum length of compressible silicone rubber tubing may be used in the pump only. Before use, the tubing must be thoroughly rinsed with methanol, followed by repeated rinsing with reagent water to minimize sample contamination. An integrating flow meter is used to collect proportional composite samples.

6.2 Equipment for glassware cleaning

Note: If blanks from bottles or other glassware or with fewer cleaning steps than required above show no detectable CB contamination, unnecessary cleaning steps and equipment may be eliminated.

6.2.1 Laboratory sink with overhead fume hood

6.2.2 Kiln—Capable of reaching 450 °C within 2 hours and maintaining 450 - 500 °C within ± 10 °C, with temperature controller and safety switch (Cress Manufacturing Co, Santa Fe Springs, CA, B31H, X31TS, or equivalent). See the precautions in Section 4.2.3.

6.3 Equipment for sample preparation

6.3.1 Laboratory fume hood of sufficient size to contain the sample preparation equipment listed below.

6.3.2 Glove box (optional)

6.3.3 Tissue homogenizer—VirTis Model 45 Macro homogenizer (American Scientific Products H-3515, or equivalent) with stainless steel Macro-shaft and Turbo-shear blade.

6.3.4 Meat grinder—Hobart, or equivalent, with 3- to 5-mm holes in inner plate.

Method 1668A with corrections and changes through August 20, 2003

- 6.3.5** Equipment for determining percent moisture
 - 6.3.5.1** Oven—Capable of maintaining a temperature of 110 ± 5 °C
 - 6.3.5.2** Desiccator
- 6.3.6** Balances
 - 6.3.6.1** Analytical—Capable of weighing 0.1 mg
 - 6.3.6.2** Top loading—Capable of weighing 10 mg
- 6.4** Extraction apparatus
 - 6.4.1** Water samples
 - 6.4.1.1** pH meter, with combination glass electrode
 - 6.4.1.2** pH paper, wide range (Hydrion Papers, or equivalent)
 - 6.4.1.3** Graduated cylinder, 1-L capacity
 - 6.4.1.4** Liquid/liquid extraction—Separatory funnels, 250-, 500-, and 2000-mL, with fluoropolymer stopcocks
 - 6.4.1.5** Solid-phase extraction
 - 6.4.1.5.1** 1-L filtration apparatus, including glass funnel, frit support, clamp, adapter, stopper, filtration flask, and vacuum tubing (Figure 4). For wastewater samples, the apparatus should accept 90 or 144 mm disks. For drinking water or other samples containing low solids, smaller disks may be used.
 - 6.4.1.5.2** Vacuum source—Capable of maintaining 25 in. Hg, equipped with shutoff valve and vacuum gauge
 - 6.4.1.5.3** Glass-fiber filter—Whatman GMF 150 (or equivalent), 1 micron pore size, to fit filtration apparatus in Section 6.4.1.5.1
 - 6.4.1.5.4** Solid-phase extraction disk containing octadecyl (C_{18}) bonded silica uniformly enmeshed in an inert matrix—Fisher Scientific 14-378F (or equivalent), to fit filtration apparatus in Section 6.4.1.5.1
 - 6.4.1.6** Continuous liquid/liquid extraction (CLLE)—Fluoropolymer or glass connecting joints and stopcocks without lubrication, 1.5-2 L capacity (Hershberg-Wolf Extractor, Cal-Glass, Costa Mesa, California, 1000 mL or 2000 mL, or equivalent).

- 6.4.2** Soxhlet/Dean-Stark (SDS) extractor (Figure 5 and Reference 11) for filters and solid/sludge samples
 - 6.4.2.1** Soxhlet—50-mm ID, 200-mL capacity with 500-mL flask (Cal-Glass LG-6900, or equivalent, except substitute 500-mL round-bottom flask for 300-mL flat-bottom flask)
 - 6.4.2.2** Thimble—43 × 123 to fit Soxhlet (Cal-Glass LG-6901-122, or equivalent)
 - 6.4.2.3** Moisture trap—Dean Stark or Barret with fluoropolymer stopcock, to fit Soxhlet
 - 6.4.2.4** Heating mantle—Hemispherical, to fit 500-mL round-bottom flask (Cal-Glass LG-8801-112, or equivalent)
 - 6.4.2.5** Variable transformer—Powerstat (or equivalent), 110-volt, 10-amp
- 6.4.3** Beakers—400- to 500-mL
- 6.4.4** Spatulas—Stainless steel
- 6.5** Filtration apparatus
 - 6.5.1** Pyrex glass wool—Solvent-extracted using a Soxhlet or SDS extractor for 3 hours minimum
 - 6.5.2** Glass funnel—125- to 250-mL
 - 6.5.3** Glass-fiber filter paper—Whatman GF/D (or equivalent), to fit glass funnel in Section 6.5.2.
 - 6.5.4** Drying column—15- to 20-mm ID Pyrex chromatographic column equipped with coarse-glass frit or glass-wool plug
 - 6.5.5** Buchner funnel—15-cm
 - 6.5.6** Glass-fiber filter paper for Buchner funnel above
 - 6.5.7** Filtration flasks—1.5- to 2.0-L, with side arm
 - 6.5.8** Pressure filtration apparatus—Millipore YT30 142 HW, or equivalent
- 6.6** Centrifuge apparatus
 - 6.6.1** Centrifuge—Capable of rotating 500-mL centrifuge bottles or 15-mL centrifuge tubes at 5,000 rpm minimum
 - 6.6.2** Centrifuge bottles—500-mL, with screw-caps, to fit centrifuge

6.6.3 Centrifuge tubes—12- to 15-mL, with screw-caps, to fit centrifuge

6.7 Cleanup apparatus

6.7.1 Automated gel permeation chromatograph (Analytical Biochemical Labs, Inc, Columbia, MO, Model GPC Autoprep 1002, or equivalent)

6.7.1.1 Column—600-700 mm long × 25 mm ID glass, packed with 70 g of 200-400 mesh SX-3 Bio-beads (Bio-Rad Laboratories, Richmond, CA, or equivalent)

6.7.1.2 Syringe—10-mL, with Luer fitting

6.7.1.3 Syringe filter holder—stainless steel, and glass-fiber or fluoropolymer filters (Gelman 4310, or equivalent)

6.7.1.4 UV detectors—254-nm, preparative or semi-preparative flow cell (Isco, Inc., Type 6; Schmadzu, 5-mm path length; Beckman-Altex 152W, 8- μ L micro-prep flow cell, 2-mm path; Pharmacia UV-1, 3-mm flow cell; LDC Milton-Roy UV-3, monitor #1203; or equivalent).

6.7.2 Reverse-phase high-performance liquid chromatograph (Reference 4)

6.7.2.1 Pump—Perkin-Elmer Series 410, or equivalent

6.7.2.2 Injector—Perkin-Elmer ISS-100 Autosampler, or equivalent

6.7.2.3 6-Port switching valve—Valco N60, or equivalent

6.7.2.4 Column—Hypercarb, 100 x 4.6 mm, 5 μ m particle size, Keystone Scientific, or equivalent

6.7.2.5 Detector—Altex 110A (or equivalent) operated at 0.02 AUFS at 235 nm

6.7.2.6 Fraction collector—Isco Foxy II, or equivalent

6.7.3 Pipets

6.7.3.1 Disposable, Pasteur, 150-mm long x 5-mm ID (Fisher Scientific 13-678-6A, or equivalent)

6.7.3.2 Disposable, serological, 50-mL (8- to 10- mm ID)

6.7.4 Glass chromatographic columns

6.7.4.1 150-mm long x 8-mm ID, (Kontes K-420155, or equivalent) with coarse-glass frit or glass-wool plug and 250-mL reservoir

6.7.4.2 200-mm long x 15-mm ID, with coarse-glass frit or glass-wool plug and 250-mL reservoir

- 6.7.4.3** 300-mm long x 22-mm ID, with coarse-glass frit, 300-mL reservoir, and glass or fluoropolymer stopcock
- 6.7.5** Oven—For baking and storage of adsorbents, capable of maintaining a constant temperature (± 5 °C) in the range of 105-250 °C

6.8 Concentration apparatus

- 6.8.1** Rotary evaporator—Buchi/Brinkman-American Scientific No. E5045-10 or equivalent, equipped with a variable temperature water bath
 - 6.8.1.1** Vacuum source for rotary evaporator equipped with shutoff valve at the evaporator and vacuum gauge
 - 6.8.1.2** A recirculating water pump and chiller are recommended, as use of tap water for cooling the evaporator wastes large volumes of water and can lead to inconsistent performance as water temperatures and pressures vary.
 - 6.8.1.3** Round-bottom flask—100-mL and 500-mL or larger, with ground-glass fitting compatible with the rotary evaporator
- 6.8.2** Kuderna-Danish (K-D) concentrator
 - 6.8.2.1** Concentrator tube—10-mL, graduated (Kontes K-570050-1025, or equivalent) with calibration verified. Ground-glass stopper (size 19/22 joint) is used to prevent evaporation of extracts.
 - 6.8.2.2** Evaporation flask—500-mL (Kontes K-570001-0500, or equivalent), attached to concentrator tube with springs (Kontes K-662750-0012 or equivalent)
 - 6.8.2.3** Snyder column—Three-ball macro (Kontes K-503000-0232, or equivalent)
 - 6.8.2.4** Boiling chips
 - 6.8.2.4.1** Glass or silicon carbide—Approximately 10/40 mesh, extracted with methylene chloride and baked at 450 °C for one hour minimum
 - 6.8.2.4.2** Fluoropolymer (optional)—Extracted with methylene chloride
 - 6.8.2.5** Water bath—Heated, with concentric ring cover, capable of maintaining a temperature within ± 2 °C, installed in a fume hood
- 6.8.3** Nitrogen evaporation apparatus—Equipped with water bath controlled in the range of 30 - 60 °C (N-Evap, Organomation Associates, Inc., South Berlin, MA, or equivalent), installed in a fume hood
- 6.8.4** Sample vials

6.8.4.1 Amber glass, 2- to 5-mL with fluoropolymer-lined screw-cap

6.8.4.2 Glass, 0.3-mL, conical, with fluoropolymer-lined screw or crimp cap

6.9 Gas chromatograph—Must have splitless or on-column injection port for capillary column, temperature program with isothermal hold, and must meet all of the performance specifications in Section 10.

6.9.1 GC column—Any GC column or column system (2 or more columns) that provides unique resolution and identification of the Toxics for determination of a TEQ_{PCB} using TEFs (Reference 1). Isomers may be unresolved so long as they have the same TEF and response factor and so long as these unresolved isomers are uniquely resolved from all other congeners. For example, the SPB-octyl column (Section 6.9.1.3) achieves unique GC resolution of all Toxics except congeners with congener numbers 156 and 157. This isomeric pair is uniquely resolved from all other congeners and these congeners have the same TEF and response factor.

6.9.1.1 If an SPB-octyl column is used, it must meet the specification in Section 6.9.1 and the following additional specifications:

6.9.1.1.1 The retention time for decachlorobiphenyl (DFB; PCB 209) must be greater than 55 minutes.

6.9.1.1.2 The column must uniquely resolve congeners 34 from 23 and 187 from 182, and congeners 156 and 157 must co-elute within 2 seconds at the peak maximum. Unique resolution means a valley height less than 40 percent of the shorter of the two peaks that result when the Diluted combined 209 congener solution (Section 7.10.2.2) is analyzed (see Figures 6 and 7).

6.9.1.1.3 The column must be replaced when any of the criteria in Sections 6.9.1 - 6.9.1.1.2 are not met.

6.9.1.2 If a column or column system alternate to the SPB-octyl column is used, specifications similar to those for the SPB-octyl column (Sections 6.9.1 - 6.9.1.1.2) must be developed and be functionally equivalent to those specifications.

6.9.1.3 Suggested column— 30 ± 5 -m long x 0.25 ± 0.02 -mm ID; 0.25- μ m film SPB-octyl (Supelco 2-4218, or equivalent). This column is capable of meeting the requirements in Sections 6.9.1 - 6.9.1.1.2.

Note: The SPB-octyl column is subject to rapid degradation when exposed to oxygen. The analyst should exclude oxygen from the carrier gas, should eliminate air leaks, and should cool the injector, column, and transfer line before opening the column to the atmosphere. For further information on precluding oxidation, contact the column manufacturer.

6.9.1.4 Column for resolution of additional congeners—See Appendix A for details on the DB-1 column. The DB-1 column is optional and is capable of

uniquely resolving the congener pair with congener numbers 156 and 157. When used in combination with the SPB-octyl column (Section 6.9.1.3), the two-column system is capable of resolving a total of approximately 180 CB congeners.

- 6.10** Mass spectrometer—28- to 40-eV electron impact ionization, must be capable of selectively monitoring a minimum of 22 exact m/z's minimum at high resolution ($\geq 10,000$) during a period less than 1.5 seconds, and must meet all of the performance specifications in Section 10.
- 6.11** GC/MS interface—The mass spectrometer (MS) must be interfaced to the GC such that the end of the capillary column terminates within 1 cm of the ion source but does not intercept the electron or ion beams.
- 6.12** Data system—Capable of collecting, recording, storing, and processing MS data
 - 6.12.1** Data acquisition—The signal at each exact m/z must be collected repetitively throughout the monitoring period and stored on a mass storage device.
 - 6.12.2** Response factors and multipoint calibrations—The data system must record and maintain lists of response factors (response ratios for isotope dilution) and multipoint calibrations. Computations of relative standard deviation (RSD) are to be used to test calibration linearity. Statistics on initial (Section 9.4) and ongoing (Section 15.5.4) performance should be computed and maintained, either on the instrument data system, or on a separate computer system.

7.0 Reagents and standards

7.1 pH adjustment and back-extraction

- 7.1.1** Potassium hydroxide—Dissolve 20 g reagent grade KOH in 100 mL reagent water.
- 7.1.2** Sulfuric acid—Reagent grade (specific gravity 1.84)
- 7.1.3** Hydrochloric acid—Reagent grade, 6N
- 7.1.4** Sodium chloride—Reagent grade, prepare at 5% (w/v) solution in reagent water

7.2 Solution drying and evaporation

- 7.2.1** Solution drying—Sodium sulfate, reagent grade, granular, anhydrous (Baker 3375, or equivalent), rinsed with methylene chloride (20 mL/g), baked at 400 °C for 1 hour minimum, cooled in a desiccator, and stored in a pre-cleaned glass bottle with screw-cap that prevents moisture from entering. If, after heating, the sodium sulfate develops a noticeable grayish cast (due to the presence of carbon in the crystal matrix), that batch of reagent is not suitable for use and should be discarded. Extraction with methylene chloride (as opposed to simple rinsing) and baking at a lower temperature may produce sodium sulfate that is suitable for use.

7.2.2 Tissue drying—Sodium sulfate, reagent grade, powdered, treated and stored as in Section 7.2.1

7.2.3 Prepurified nitrogen

7.3 Extraction

7.3.1 Solvents—Acetone, toluene, cyclohexane, hexane, methanol, methylene chloride, isooctane, and nonane; distilled in glass, pesticide quality, lot-certified to be free of interferences

Note: Some solvents; e.g., isooctane and nonane, may need to be re-distilled to eliminate CB backgrounds.

7.3.2 White quartz sand, 60/70 mesh—For Soxhlet/Dean-Stark extraction (Aldrich Chemical, Cat. No. 27-437-9, or equivalent). Bake at 450 °C for 4 hour minimum.

7.4 GPC calibration solution—Prepare a solution containing 2.5 mg/mL corn oil, 0.05 mg/mL bis(2-ethylhexyl) phthalate (BEHP), 0.01 mg/mL methoxychlor, 0.002 mg/mL perylene, and 0.008 mg/mL sulfur, or at concentrations appropriate to the response of the detector.

7.5 Adsorbents for sample cleanup

7.5.1 Silica gel

7.5.1.1 Activated silica gel—100-200 mesh, Supelco 1-3651 (or equivalent), 100-200 mesh, rinsed with methylene chloride, baked at 180 °C for a minimum of 1 hour, cooled in a desiccator, and stored in a precleaned glass bottle with screw-cap that prevents moisture from entering.

7.5.1.2 Acid silica gel (30% w/w)—Thoroughly mix 44 g of concentrated sulfuric acid with 100 g of activated silica gel in a clean container. Break up aggregates with a stirring rod until a uniform mixture is obtained. Store in a screw-capped bottle with fluoropolymer-lined cap.

7.5.1.3 Basic silica gel—Thoroughly mix 30 g of 1N sodium hydroxide with 100 g of activated silica gel in a clean container. Break up aggregates with a stirring rod until a uniform mixture is obtained. Store in a screw-capped bottle with fluoropolymer-lined cap.

7.5.1.4 Potassium silicate

7.5.1.4.1 Dissolve 56 g of high purity potassium hydroxide (Aldrich, or equivalent) in 300 mL of methanol in a 750- to 1000-mL flat-bottom flask.

7.5.1.4.2 Add 100 g of activated silica gel (Section 7.5.1.1) and a stirring bar, and stir on an explosion-proof hot plate at 60-70 °C for 1-2 hours.

7.5.1.4.3 Decant the liquid and rinse the potassium silicate twice with 100-mL portions of methanol, followed by a single rinse with 100 mL of methylene chloride.

7.5.1.4.4 Spread the potassium silicate on solvent-rinsed aluminum foil and dry for 2-4 hours in a hood. Observe the precaution in Section 4.8.

7.5.1.4.5 Activate overnight at 200-250 °C prior to use.

7.5.2 Carbon

7.5.2.1 Caropak C—(Supelco 1-0258, or equivalent)

7.5.2.2 Celite 545—(Supelco 2-0199, or equivalent)

7.5.2.3 Thoroughly mix 18.0 g Caropak C and 18.0 g Celite 545 to produce a 50% w/w mixture. Activate the mixture at 130 °C for a minimum of 6 hours. Store in a desiccator.

Note: The carbon column has been included in this Method to allow separation of co-planar congeners 77, 126, and 169 from other congeners and interferences, should such separation be desired.

7.5.3 Anthropogenic isolation column—Pack the column in Section 6.7.4.3 from bottom to top with the following:

7.5.3.1 2 g silica gel (Section 7.5.1.1)

7.5.3.2 2 g potassium silicate (Section 7.5.1.4)

7.5.3.3 2 g granular anhydrous sodium sulfate (Section 7.2.1)

7.5.3.4 10 g acid silica gel (Section 7.5.1.2)

7.5.3.5 2 g granular anhydrous sodium sulfate

7.5.4 Florisil column

7.5.4.1 Florisil—PR grade, 60-100 mesh (U.S. Silica Corp, Berkeley Springs, WV, or equivalent). Alternatively, prepacked Florisil columns may be used. Use the following procedure for Florisil activation and column packing.

7.5.4.1.1 Fill a clean 1- to 2-L bottle ½ to 2/3 full with Florisil and place in an oven at 130-150 °C for a minimum of three days to activate the Florisil.

7.5.4.1.2 Immediately prior to use, dry pack a 300-mm x 22-mm ID glass column (Section 6.7.4.3) bottom to top with 0.5-1.0 cm of warm

to hot anhydrous sodium sulfate (Section 7.2.1), 10-10.5 cm of warm to hot activated Florisil (Section 7.5.4.1.1), and 1-2 cm of warm to hot anhydrous sodium sulfate. Allow the column to cool and wet immediately with 100 mL of n-hexane to prevent water from entering.

7.5.4.2 Using the procedure in Section 13.7.3, establish the elution pattern for each carton of Florisil or each lot of Florisil columns received.

7.6 Reference matrices—Matrices in which the CBs and interfering compounds are not detected by this Method

7.6.1 Reagent water—Bottled water purchased locally, or prepared by passage through activated carbon

7.6.2 High-solids reference matrix—Playground sand or similar material. Prepared by extraction with methylene chloride and/or baking at 450 °C for a minimum of 4 hours.

7.6.3 Paper reference matrix—Glass-fiber filter, Gelman type A, or equivalent. Cut paper to simulate the surface area of the paper sample being tested.

7.6.4 Tissue reference matrix—Corn or other vegetable oil.

7.6.5 Other matrices—This Method may be verified on any reference matrix by performing the tests given in Section 9.2. Ideally, the matrix should be free of the CBs, but in no case must the background level of the CBs in the reference matrix exceed the minimum levels in Table 2. If low background levels of the CBs are present in the reference matrix, the spike level of the analytes used in Section 9.2 should be increased to provide a spike-to-background ratio of approximately 5 (Reference 11).

7.7 Standard solutions—Prepare from materials of known purity and composition or purchase as solutions or mixtures with certification to their purity, concentration, and authenticity. If the chemical purity is 98 % or greater, the weight may be used without correction to calculate the concentration of the standard. Observe the safety precautions in Section 5 and the recommendation in Section 5.1.2.

Note: Native PCB standards are available from several suppliers. ¹³C₁₂-labeled congeners are available from Cambridge Isotope Laboratories and Wellington Laboratories, and may be available from other suppliers. Listing of these suppliers does not constitute a recommendation or endorsement for use. Part numbers are for reference only.

7.7.1 For preparation of stock solutions from neat materials, dissolve an appropriate amount of assayed reference material in solvent. For example, weigh 1 to 2 mg of PCB 126 to three significant figures in a 10-mL ground-glass-stoppered volumetric flask and fill to the mark with nonane. After the compound is completely dissolved, transfer the solution to a clean 15-mL vial with fluoropolymer-lined cap.

7.7.2 When not being used, store standard solutions in the dark at room temperature in screw-capped vials with fluoropolymer-lined caps. Place a mark on the vial at the level

of the solution so that solvent loss by evaporation can be detected. Replace the solution if solvent loss has occurred.

7.8 Native (unlabeled) stock solutions

7.8.1 Native Toxics/LOC stock solution—Prepare to contain the native Toxics and LOC CBs at the concentrations shown in Table 3, or purchase Accu-Standard M1668A-C-NT-LOC-WD-GCPC, or equivalent. If additional CBs are to be determined by isotope dilution (e.g., 170 and 180), include the additional native compounds in this stock solution.

7.8.2 Native 209 CB congener stock solutions—Solutions containing CB congeners to calibrate the SPB-octyl column.

Note: *If a column other than the SPB-octyl column is used, solutions that will allow separation of all 209 congeners on that column must be prepared.*

7.8.2.1 Native congener mix stock solutions for separation of individual congeners on the SPB-octyl column—Prepare the five solutions with the congeners listed in Table 4 at the concentrations shown in Table 3 or purchase Accu-Standard M-1668A-1, M-1668A-2, M-1668A-3, M-1668-4, and M-1668-5, or equivalent.

7.8.2.2 Combined 209 congener stock solution—Combine equal volumes of the standards in Section 7.8.2.1 to form a stock solution containing all CB congeners. This solution will be at 1/5 the concentration of the 5 individual solutions.

7.8.3 Stock solutions should be checked for signs of degradation prior to the preparation of calibration or performance test standards. Reference standards that can be used to determine the accuracy of standard solutions are available from several vendors.

7.9 Labeled compound stock solutions (Table 3)

7.9.1 Labeled Toxics/LOC/window-defining stock solution—Prepare in isooctane or nonane at the concentrations in Table 3 or purchase Cambridge Isotope Laboratories (CIL) EC-4977, or equivalent. If additional CBs are to be determined by isotope dilution (e.g., 170 and 180), include the additional labeled compounds in this stock solution.

7.9.2 Labeled cleanup standard stock solution—Prepare labeled CBs 28, 111, and 178 in isooctane or nonane at the concentration shown in Table 3 or purchase CIL EC-4978, or equivalent.

7.9.3 Labeled injection internal standard stock solution—Prepare labeled CBs 9, 52, 101, 138, and 194 in nonane or isooctane at the concentrations shown in Table 3, or purchase CIL EC-4979, or equivalent.

7.10 Calibration standards

7.10.1 Calibration standards—Combine and dilute the solutions in Sections 7.8.1 and 7.9 to produce the calibration solutions in Table 5 or purchase CIL EC-4976, or equivalent, for the CS-1 to CS-5 set of calibration solutions. If a 6-point calibration is used, prepare the CS-0.2 solution or purchase CIL EC-4976-0.2, or equivalent. These solutions permit the relative response (labeled to native) and response factor to be measured as a function of concentration. The CS-3 standard (CIL EC-4976-3, or equivalent) is used for calibration verification (VER).

7.10.2 Solutions of congener mixes

7.10.2.1 Diluted individual solutions

7.10.2.1.1 The 5 individual solutions, when analyzed individually, allow resolution of all 209 congeners on the SPB-octyl column, and are used for establishing retention time and other data for each congener. The elution order of the congeners present in each of the 5 solutions (Section 7.8.2.1) is given in Table 4.

7.10.2.1.2 Individually combine an aliquot of each individual mix stock solution (Section 7.8.2.1) with an aliquot of the Labeled Toxics/LOC/window-defining stock solution (Section 7.9.1), the Labeled cleanup standard stock solution (Section 7.9.2), and the Labeled injection internal standard stock solution (7.9.3) to produce concentrations of 100 ng/mL for the labeled compounds and 25, 50, and 75 ng/mL for the MoCB-TrCB, TeCB-HpCB, and OcCB-DeCB congeners, respectively, as shown in Table 3.

7.10.2.2 Diluted combined 209 congener solution

7.10.2.2.1 This solution combines the 5 individual mixes with the labeled compounds to allow single-point calibration of the congeners not included in the multi-point calibration, and establishes an average response factor for the co-eluting isomeric congeners.

7.10.2.2.2 Combine an aliquot of the combined 209 congener solution (Section 7.8.2.2) with an aliquot of the Labeled Toxics/LOC/window-defining stock solution (Section 7.9.1), the Labeled cleanup standard stock solution (Section 7.9.2), and the Labeled injection internal standard stock solution (7.9.3) to produce the same concentrations as in the diluted individual mix solutions (Section 7.10.2.1.2 and Table 3).

7.11 Native Toxics/LOC standard spiking solution—Used for determining initial precision and recovery (IPR; Section 9.2) and ongoing precision and recovery (OPR; Section 15.5). Dilute the Native Toxics/LOC stock solution (Section 7.8.1) with acetone to produce a concentration of the Toxics at 1 ng/mL, as shown in Table 3. When 1 mL of this solution spiked into the IPR (Section 9.2.1) or OPR (Section 15.5) and concentrated to a final volume of 20 μ L, the

concentration in the final volume will be 50 ng/mL (50 pg/μL). Prepare only the amount necessary for each reference matrix with each sample batch.

- 7.12** Labeled Toxics/LOC/window-defining standard spiking solution—This solution is spiked into each sample (Section 9.3) and into the IPR (Section 9.2.1), OPR (Section 15.5), and blank (Section 9.5) to measure recovery. Dilute the Labeled Toxics/LOC/window-defining stock solution (Section 7.9.1) with acetone to produce a concentration of the labeled compounds at 2 ng/mL, as shown in Table 3. When 1 mL of this solution is spiked into an IPR, OPR, blank, or sample and concentrated to a final extract volume of 20 μL, the concentration in the final extract volume will be 100 ng/mL (100 pg/μL). Prepare only the amount necessary for each reference matrix with each sample batch.
- 7.13** Labeled cleanup standard spiking solution—This solution is spiked into each extract prior to cleanup to measure the efficiency of the cleanup process. Dilute the Labeled cleanup standard stock solution (Section 7.9.2) in methylene chloride to produce a concentration of the cleanup standards at 2 ng/mL, as shown in Table 3. When 1 mL of this solution is spiked into a sample extract and concentrated to a final volume of 20 μL, the concentration in the final volume will be 100 ng/mL (100 pg/μL).
- 7.14** Labeled injection internal standard spiking solution—This solution is added to each concentrated extract prior to injection into the HRGC/HRMS. Dilute the Labeled injection internal standard stock solution (Section 7.9.3) in nonane to produce a concentration of the injection internal standards at 1000 ng/mL, as shown in Table 3. When 2 μL of this solution is spiked into a 20 μL extract, the concentration of each injection internal standard will be nominally 100 ng/mL (100 pg/μL).

Note: The addition of 2 μL of the Labeled injection internal standard spiking solution to a 20 μL final extract has the effect of diluting the concentration of the components in the extract by 10%. Provided all calibration solutions and all extracts undergo this dilution as a result of adding the Labeled injection internal standard spiking solution, the effect of the 10% solution is compensated, and correction for this dilution should not be made.

- 7.15** QC Check Sample—A QC Check Sample should be obtained from a source independent of the calibration standards. Ideally, this check sample would be a certified Standard Reference Material (SRM) containing the CBs in known concentrations in a sample matrix similar to the matrix under test. The National Institute of Standards and Technology (NIST) in Gaithersburg, Maryland has SRMs, and the Institute for National Measurement Standards of the National Research Council of Canada in Ottawa has certified reference materials (CRMs), for CBs in various matrices.
- 7.16** Stability of solutions—Standard solutions used for quantitative purposes (Sections 7.9 through 7.14) should be assayed periodically (e.g., every 6 months) against SRMs from NIST (if available), or certified reference materials from a source that will attest to the authenticity and concentration, to assure that the composition and concentrations have not changed.

8.0 Sample collection, preservation, storage, and holding times

- 8.1** Collect samples in amber glass containers following conventional sampling practices (Reference 13).
- 8.2** Aqueous samples
 - 8.2.1** Samples that flow freely are collected as grab samples or in refrigerated bottles using automatic sampling equipment.
 - 8.2.2** If residual chlorine is present, add 80 mg sodium thiosulfate per liter of water. EPA Methods 330.4 and 330.5 may be used to measure residual chlorine (Reference 14).
 - 8.2.3** Maintain aqueous samples in the dark at $<6^{\circ}\text{C}$ from the time of collection until receipt at the laboratory. If the sample will be frozen, allow room for expansion. Store in the dark at $<6^{\circ}\text{C}$.
- 8.3** Solid, mixed-phase, semi-solid, and oily samples, excluding tissue.
 - 8.3.1** Collect samples as grab samples using wide-mouth jars.
 - 8.3.2** Maintain solid, semi-solid, oily, and mixed-phase samples in the dark at $<6^{\circ}\text{C}$ from the time of collection until receipt at the laboratory. Store solid, semi-solid, oily, and mixed-phase samples in the dark at less than -10°C .
- 8.4** Fish and other tissue samples
 - 8.4.1** Fish may be cleaned, filleted, or processed in other ways in the field, such that the laboratory may expect to receive whole fish, fish fillets, or other tissues for analysis.
 - 8.4.2** Collect fish, wrap in aluminum foil, and maintain at $<6^{\circ}\text{C}$ from the time of collection until receipt at the laboratory, to a maximum time of 24 hours. If a longer transport time is necessary, freeze the sample. Ideally, fish should be frozen upon collection and shipped to the laboratory under dry ice.
 - 8.4.3** Freeze tissue samples upon receipt at the laboratory and maintain in the dark at less than -10°C until prepared. Maintain unused sample in the dark at less than -10°C .
- 8.5** Holding times
 - 8.5.1** There are no demonstrated maximum holding times associated with the CBs in aqueous, solid, semi-solid, tissue, or other sample matrices. If stored in the dark at $<6^{\circ}\text{C}$, aqueous samples may be stored for up to one year. Similarly, if stored in the dark at less than -10°C , solid, semi-solid, multi-phase, and tissue samples may be stored for up to one year.
 - 8.5.2** Store sample extracts in the dark at less than -10°C until analyzed. If stored in the dark at less than -10°C , sample extracts may be stored for one year.

9.0 Quality assurance/quality control

- 9.1** Each laboratory that uses this Method is required to operate a formal quality assurance program (Reference 15). The minimum requirements of this program consist of an initial demonstration of laboratory capability, analysis of samples spiked with labeled compounds to evaluate and document data quality, and analysis of standards and blanks as tests of continued performance. Laboratory performance is compared to established performance criteria to determine if the results of analyses meet the performance characteristics of the Method.

If the Method is to be applied to sample matrix other than water (e.g., soils, filter cake, compost, tissue) the most appropriate alternate reference matrix (Sections 7.6.2 - 7.6.5 and 7.15) is substituted for the reagent water matrix (Section 7.6.1) in all performance tests.

- 9.1.1** The laboratory must make an initial demonstration of the ability to generate acceptable precision and recovery with this Method. This demonstration is given in Section 9.2.

- 9.1.2** In recognition of advances that are occurring in analytical technology, and to overcome matrix interferences, the laboratory is permitted certain options to improve separations or lower the costs of measurements. These options include alternate extraction, concentration, and cleanup procedures, and changes in columns and detectors. Alternate determinative techniques, such as the substitution of spectroscopic or immuno-assay techniques, and changes that degrade Method performance, are not allowed. If an analytical technique other than the techniques specified in this Method is used, that technique must have a specificity equal to or greater than the specificity of the techniques in this Method for the analytes of interest.

- 9.1.2.1** Each time a modification is made to this Method, the laboratory is required to repeat the procedure in Section 9.2. If the detection limit of the Method will be affected by the change, the laboratory is required to demonstrate that the MDLs (40 CFR Part 136, Appendix B) are lower than one-third the regulatory compliance level or one-third the EMDLs in this Method, whichever are greater. If calibration will be affected by the change, the instrument must be recalibrated per Section 10. Once the modification is demonstrated to produce results equivalent or superior to results produced by this Method as written, that modification may be used routinely thereafter, so long as the other requirements in this Method are met (e.g., labeled compound recovery).

- 9.1.2.2** The laboratory is required to maintain records of modifications made to this Method. These records include the following, at a minimum:

- 9.1.2.2.1** The names, titles, addresses, and telephone numbers of the analyst(s) that performed the analyses and modification, and of the quality control officer that witnessed and will verify the analyses and modifications.

- 9.1.2.2.2** A listing of pollutant(s) measured, by name and CAS Registry number.

9.1.2.2.3 A narrative stating reason(s) for the modifications.

9.1.2.2.4 Results from all quality control (QC) tests comparing the modified method to this Method, including:

- a) Calibration (Section 10).
- b) Calibration verification (Section 15.3).
- c) Initial precision and recovery (Section 9.2).
- d) Labeled compound recovery (Section 9.3).
- e) Analysis of blanks (Section 9.5).
- f) Accuracy assessment (Section 9.4).

9.1.2.2.5 Data that will allow an independent reviewer to validate each determination by tracing the instrument output (peak height, area, or other signal) to the final result. These data are to include:

- a) Sample numbers and other identifiers.
- b) Extraction dates.
- c) Analysis dates and times.
- d) Analysis sequence/run chronology.
- e) Sample weight or volume (Section 11).
- f) Extract volume prior to each cleanup step (Section 13).
- g) Extract volume after each cleanup step (Section 13).
- h) Final extract volume prior to injection (Section 14).
- i) Injection volume (Section 14.3).
- j) Dilution data, differentiating between dilution of a sample or extract (Section 17.5).
- k) Instrument and operating conditions.
- l) Column (dimensions, liquid phase, solid support, film thickness, etc).
- m) Operating conditions (temperatures, temperature program, flow rates).
- n) Detector (type, operating conditions, etc).
- o) Chromatograms, printer tapes, and other recordings of raw data.
- p) Quantitation reports, data system outputs, and other data to link the raw data to the results reported.

9.1.2.3 Alternate HRGC columns and column systems—See Sections 6.9.1. If a column or column system alternate to those specified in this Method is used, that column or column system must meet the requirements in Section 6.9.1 - 6.9.1.1.3.

9.1.3 Analyses of method blanks are required to demonstrate freedom from contamination (Section 4.3). The procedures and criteria for analysis of a method blank are described in Sections 9.5 and 15.6.

- 9.1.4** The laboratory must spike all samples with labeled compounds to monitor Method performance. This test is described in Section 9.3. When results of these spikes indicate atypical Method performance for samples, the samples are diluted to bring Method performance within acceptable limits. Procedures for dilution are given in Section 17.5.
- 9.1.5** The laboratory must, on an ongoing basis, demonstrate through calibration verification and the analysis of the ongoing precision and recovery standard (OPR) and blanks that the analytical system is in control. These procedures are given in Sections 15.1 through 15.6.
- 9.1.6** The laboratory should maintain records to define the quality of data generated. Development of accuracy statements is described in Section 9.4.
- 9.2** Initial precision and recovery (IPR)—To establish the ability to generate acceptable precision and recovery, the laboratory must perform the following operations.
- 9.2.1** For low solids (aqueous) samples, extract, concentrate, and analyze four 1-L aliquots of reagent water spiked with 1 mL each of the Native Toxics/LOC spiking solution (Section 7.11), the Labeled Toxics/LOC/window-defining standard spiking solution (Section 7.12), and the Labeled cleanup standard spiking solution (Section 7.13), according to the procedures in Sections 11 through 18. For an alternative sample matrix, four aliquots of the alternative reference matrix (Section 7.6) are used. All sample processing steps that are to be used for processing samples, including preparation (Section 11), extraction (Section 12), and cleanup (Section 13), must be included in this test.
- 9.2.2** Using results of the set of four analyses, compute the average percent recovery (X) of the extracts and the relative standard deviation (RSD) of the concentration for each compound, by isotope dilution for CBs with a labeled analog, and by internal standard for CBs without a labeled analog and for the labeled compounds.
- 9.2.3** For each CB and labeled compound, compare RSD and X with the corresponding limits for initial precision and recovery in Table 6. If RSD and X for all compounds meet the acceptance criteria, system performance is acceptable and analysis of blanks and samples may begin. If, however, any individual RSD exceeds the precision limit or any individual X falls outside the range for recovery, system performance is unacceptable for that compound. Correct the problem and repeat the test (Section 9.2).
- 9.3** To assess Method performance on the sample matrix, the laboratory must spike all samples with the Labeled Toxics/LOC/window-defining standard spiking solution (Section 7.12) and all sample extracts with the Labeled cleanup standard spiking solution (Section 7.13).
- 9.3.1** Analyze each sample according to the procedures in Sections 11 through 18.
- 9.3.2** Compute the percent recovery of the labeled Toxics/LOC/window-defining congeners and the labeled cleanup congeners using the internal standard method (Section 17.2).

- 9.3.3** The recovery of each labeled compound must be within the limits in Table 6. If the recovery of any compound falls outside of these limits, Method performance is unacceptable for that compound in that sample. Additional cleanup procedures must then be employed to attempt to bring the recovery within the normal range. If the recovery cannot be brought within the normal range after all cleanup procedures have been employed, water samples are diluted and smaller amounts of soils, sludges, sediments, and other matrices are analyzed per Section 18.
- 9.4** It is suggested but not required that recovery of labeled compounds from samples be assessed and records maintained.
- 9.4.1** After the analysis of 30 samples of a given matrix type (water, soil, sludge, pulp, etc.) for which the labeled compounds pass the tests in Section 9.3, compute the average percent recovery (R) and the standard deviation of the percent recovery (S_R) for the labeled compounds only. Express the assessment as a percent recovery interval from $R - 2S_R$ to $R + 2S_R$ for each matrix. For example, if $R = 90\%$ and $S_R = 10\%$ for five analyses of pulp, the recovery interval is expressed as 70 to 110%.
- 9.4.2** Update the accuracy assessment for each labeled compound in each matrix on a regular basis (e.g., after each five to ten new measurements).
- 9.5** Method blanks—A reference matrix Method blank is analyzed with each sample batch (Section 4.3) to demonstrate freedom from contamination. The matrix for the Method blank must be similar to the sample matrix for the batch, e.g., a 1-L reagent water blank (Section 7.6.1), high-solids reference matrix blank (Section 7.6.2), paper matrix blank (Section 7.6.3); tissue blank (Section 7.6.4), or alternative reference matrix blank (Section 7.6.5).
- 9.5.1** Spike 1.0 mL each of the Labeled Toxics/LOC/window-defining standard spiking solution (Section 7.12), and the Labeled cleanup standard spiking solution (Section 7.13) into the Method blank, according to the procedures in Sections 11 through 18. Prepare, extract, clean up, and concentrate the Method blank. Analyze the blank immediately after analysis of the OPR (Section 15.5) to demonstrate freedom from contamination.
- 9.5.2** If any CB (Table 1) is found in the blank at greater than the minimum level (Table 2) or one-third the regulatory compliance limit, whichever is greater; or if any potentially interfering compound is found in the blank at the minimum level for each CB given in Table 2 (assuming a response factor of 1 relative to the quantitation reference in Table 2 at that level of chlorination for a potentially interfering compound; i.e., a compound not listed in this Method), analysis of samples must be halted until the sample batch is re-extracted and the extracts re-analyzed, and the blank associated with the sample batch shows no evidence of contamination at these levels. All samples must be associated with an uncontaminated Method blank before the results for those samples may be reported or used for permitting or regulatory compliance purposes.
- 9.6** QC Check Sample—Analyze the QC Check Sample (Section 7.15) periodically to assure the accuracy of calibration standards and the overall reliability of the analytical process. It is suggested that the QC Check Sample be analyzed at least quarterly.

9.7 The specifications contained in this Method can be met if the apparatus used is calibrated properly and then maintained in a calibrated state. The standards used for calibration (Section 10), calibration verification (Section 15.3), and for initial (Section 9.2) and ongoing (Section 15.5) precision and recovery should be identical, so that the most precise results will be obtained. A GC/MS instrument will provide the most reproducible results if dedicated to the settings and conditions required for determination of CBs by this Method.

9.8 Depending on specific program requirements, field replicates may be collected to determine the precision of the sampling technique, and spiked samples may be required to determine the accuracy of the analysis when the internal standard method is used.

10.0 Calibration

10.1 Establish the operating conditions necessary to meet the retention times (RTs) and relative retention times (RRTs) for the CBs in Table 2.

10.1.1 Suggested GC operating conditions:

Injector temperature:	270 °C
Interface temperature:	290 °C
Initial temperature:	75 °C
Initial time:	2 minutes
Temperature program:	75-150 °C at 15 °C/minute 150-290 °C at 2.5 °C/minute
Final time:	1 minute

Note: *All portions of the column that connect the GC to the ion source should remain at or above the interface temperature specified above during analysis to preclude condensation of less volatile compounds.*

The GC conditions may be optimized for compound separation and sensitivity. Once optimized, the same GC conditions must be used for the analysis of all standards, blanks, IPR and OPR standards, and samples.

10.1.2 Retention time calibration for the CB congeners

10.1.2.1 Separately inject each of the diluted individual congener solutions (Section 7.10.2.1.2). Establish the beginning and ending retention times for the scan descriptors in Table 7. Scan descriptors other than those listed in Table 7 may be used provided the MLs in Table 2 are met. Store the retention time (RT) and relative retention time (RRT) for each congener in the data system.

10.1.2.2 The absolute retention time of CB 209 must exceed 55 minutes on the SPB-octyl column; otherwise, the GC temperature program must be adjusted and

this test repeated until the minimum retention time criterion is met. If a GC column or column system alternate to the SPB-octyl column is used, a similar minimum retention time specification must be established for the alternate column or column systems so that interferences that may be encountered in environmental samples will be resolved from the analytes of interest. This specification is deemed to be met if the retention time of CB 209 is greater than 55 minutes on such alternate column.

10.1.2.3 Inject the Diluted combined 209 congener solution (Section 7.10.2.2 and Table 5). Adjust the chromatographic conditions and scan descriptors until the RT and RRT for all congeners are approximately within the windows in Table 2 and the column performance specifications in Sections 6.9.1 - 6.9.1.2 are met. If an alternate column is used, adjust the conditions for that column. If column performance is unacceptable, optimize the analysis conditions or replace the column and repeat the performance tests. Confirm that the scan descriptor changes at times when CBs do not elute.

10.1.2.4 After the column performance tests are passed (Section 10.1.2.2 - 10.1.2.3), calculate and store the RT and RRT for the resolved congeners and the RT and RRT for the isomeric congeners that co-elute. The windows in Table 2 were developed based on the GC conditions given in Section 10.1.1.

10.2 Mass spectrometer (MS) resolution

10.2.1 Using PFK (or other reference substance) and a molecular leak, tune the instrument to meet the minimum required resolving power of 10,000 (10% valley) at m/z 330.9792 or any other significant PFK fragment in the range of 300 to 350. For each descriptor (Table 7), monitor and record the resolution and exact m/z 's of three to five reference peaks covering the mass range of the descriptor. The level of PFK (or other reference substance) metered into the HRMS during analyses should be adjusted so that the amplitude of the most intense selected lock-mass m/z signal (regardless of the descriptor number) does not exceed 10% of the full-scale deflection for a given set of detector parameters. Under those conditions, sensitivity changes that might occur during the analysis can be more effectively monitored.

Note: *Different lots and types of PFK can contain varying levels of contamination, and excessive PFK (or other reference substance) may cause noise problems and contamination of the ion source necessitating increased frequency of source cleaning.*

10.2.2 The analysis time for CBs may exceed the long-term mass stability of the mass spectrometer. Because the instrument is operated in the high-resolution mode, mass drifts of a few ppm (e.g., 5 ppm in mass) can have serious adverse effects on instrument performance. Therefore, mass-drift correction is mandatory and a lock-mass m/z from perfluorokerosene (PFK) or other reference substance is used for drift correction. The lock-mass m/z is dependent on the exact m/z 's monitored within each descriptor, as shown in Table 7. The deviation between each monitored exact m/z and the theoretical m/z (Table 7) must be less than 5 ppm.

- 10.2.3** Obtain a selected ion current profile (SICP) at the two exact m/z's specified in Table 7 and at $\geq 10,000$ resolving power at each LOC for the native congeners and congener groups and for the labeled congeners. Because of the extensive mass range covered in each function, it may not be possible to maintain 10,000 resolution throughout the mass range during the function. Therefore, resolution must be $\geq 8,000$ throughout the mass range and must be $\geq 10,000$ in the center of the mass range for each function.
- 10.2.4** If the HRMS has the capability to monitor resolution during the analysis, it is acceptable to terminate the analysis when the resolution falls below the minimum (Section 10.2.1.3) to save re-analysis time.
- 10.3** Ion abundance ratios, minimum levels, and signal-to-noise ratios. Choose an injection volume of either 1 or 2 μL , consistent with the capability of the HRGC/HRMS instrument. Inject a 1 or 2 μL aliquot of the CS-1 calibration solution (Table 5) using the GC conditions in Section 10.1.1.
- 10.3.1** Measure the SICP areas for each congener or congener group, and compute the ion abundance ratios at the exact m/z's specified in Table 7. Compare the computed ratio to the theoretical ratio given in Table 8.
- 10.3.1.1** The exact m/z's to be monitored in each descriptor are shown in Table 7. Each group or descriptor must be monitored in succession as a function of GC retention time to ensure that the CBs of interest are detected. Additional m/z's may be monitored in each descriptor, and the m/z's may be divided among more than the descriptors listed in Table 7, provided that the laboratory is able to monitor the m/z's of all CBs that may elute from the GC in a given LOC window. The laboratory must also monitor exact m/z's for congeners at higher levels of chlorination to determine if fragments will compromise measurement of congeners at lower levels of chlorination.
- 10.3.1.2** The mass spectrometer must be operated in a mass-drift correction mode, using PFK (or other reference substance) to provide lock m/z's. The lock mass for each group of m/z's is shown in Table 7. Each lock mass must be monitored and must not vary by more than $\pm 20\%$ throughout its respective retention time window. Variations of lock mass by more than 20% indicate the presence of co-eluting interferences that raise the source pressure and may significantly reduce the sensitivity of the mass spectrometer. Re-injection of another aliquot of the sample extract may not resolve the problem and additional cleanup of the extract may be required to remove the interference. A lock mass interference or suppression in a retention time region in which CBs and labeled compounds do not elute may be ignored.
- 10.3.2** All CBs and labeled compounds in the CS-1 standard must be within the QC limits in Table 8 for their respective ion abundance ratios; otherwise, the mass spectrometer must be adjusted and this test repeated until the m/z ratios fall within the limits specified. If the adjustment alters the resolution of the mass spectrometer, resolution must be verified (Section 10.2.1) prior to repeat of the test.

- 10.3.3** Verify that the HRGC/HRMS instrument meets the estimated minimum levels (EMLs) in Table 2. The peaks representing the CBs and labeled compounds in the CS-1 calibration standard must have signal-to-noise ratios (S/N) ≥ 10 ; otherwise, the mass spectrometer must be adjusted and this test repeated until the minimum levels in Table 2 are met.

Note: The EMDLs and EMLs in Table 2 are based on the levels of contamination normally found in laboratories. Lower levels may be readily achievable if segregation and extensive cleaning of glassware is employed. If lower levels are achievable, these levels must be established as described in Section 17.6.1.4.1.

- 10.4** Calibration by isotope dilution—Isotope dilution is used for calibration of the Toxics/LOC CBs. The reference compound for each native compound is its labeled analog, as listed in Table 2. A 5- or 6-point calibration encompassing the concentration range is prepared for each native congener.

- 10.4.1** For the Toxics/LOC CBs determined by isotope dilution, the relative response (RR) (labeled to native) vs. concentration in the calibration solutions (Table 5) is computed over the calibration range according to the procedures described below. Five calibration points are employed for less-sensitive HRMS instruments (e.g., VG 70); five or six points may be employed for more-sensitive instruments (e.g., Micromass Autospec Ultima).

- 10.4.2** The response of each Toxics/LOC CB relative to its labeled analog is determined using the area responses of both the primary and secondary exact m/z's specified in Table 7, for each calibration standard, as follows:

$$RR = \frac{(A1_n + A2_n) C_l}{(A1_l + A2_l) C_n}$$

Where:

- $A1_n$ and $A2_n$ = The areas of the primary and secondary m/z's for the PCB.
 $A1_l$ and $A2_l$ = The areas of the primary and secondary m/z's for the labeled compound.
 C_l = The concentration of the labeled compound in the calibration standard (Table 4).
 C_n = The concentration of the native compound in the calibration standard (Table 4).

- 10.4.3** To calibrate the analytical system by isotope dilution, inject calibration standards CS-1 through CS-5 (Section 7.10 and Table 5) for a less sensitive instrument or CS-0.2 through CS-5 for a more sensitive instrument. Use a volume identical to the volume chosen in Section 10.3, the procedure in Section 14, and the conditions in Section 10.1.1. Compute and store the relative response (RR) for each Native Toxics/LOC CB at each concentration. Compute the average (mean) RR and the RSD of the 5 (or 6) RRs.

10.4.4 Linearity—If the RR for any Native Toxics/LOC CB is constant (less than 20% RSD), the average RR may be used for that congener; otherwise, the complete calibration curve for that congener must be used over the calibration range.

10.5 Calibration by internal standard—Internal standard calibration is applied to determination of the native CBs for which a labeled compound is not available, to determination of the Labeled Toxics/LOC/window-defining congeners and Labeled cleanup congeners for performance tests and intra-laboratory statistics (Sections 9.4 and 15.5.4), and to determination of the Labeled injection internal standards except for CB 178. The reference compound for each compound is listed in Table 2. For the native congeners (other than the Native Toxics/LOC CBs), calibration is performed at a single point using the Diluted combined 209 congener solution (Section 7.10.2.2 and Table 5). For the labeled compounds, calibration is performed using data from the 5 (or 6) points in the calibration for the Native Toxics/LOC CBs (Section 10.4).

10.5.1 Response factors—Internal standard calibration requires the determination of response factors (RF) defined by the following equation:

$$RF = \frac{(A1_s + A2_s) C_{is}}{(A1_{is} + A2_{is}) C_s}$$

Where:

- A1_s and A2_s = The areas of the primary and secondary m/z's for the PCB.
- A1_{is} and A2_{is} = The areas of the primary and secondary m/z's for the internal standard.
- C_{is} = The concentration of the internal standard (Table 5).
- C_s = The concentration of the compound in the calibration standard (Table 5).

10.5.2 To single-concentration calibrate the analytical system for native CBs other than the Native Toxics/LOC CBs by internal standard, inject the Diluted combined 209 congener solution (Section 7.10.2.2 and Table 3). Use a volume identical to the volume chosen in Section 10.3, the procedure in Section 14, and the conditions in Section 10.1.1.

10.5.3 Compute and store the response factor (RF) for all native CBs except the Native Toxics/LOC CBs. Use the average (mean) response of the labeled compounds at each level of chlorination (LOC) as the quantitation reference, to a maximum of 5 labeled congeners, as shown in Table 2. For the combinations of isomeric congeners that co-elute, compute a combined RF for the co-eluted group. For example, for congener 122, the areas at the two exact m/z's for 104L, 105L, 114L, 118L, and 123L are summed and the total area is divided by 5 (because there are 5 congeners in the quantitation reference).

Note: *All labeled congeners at each LOC are used as reference to reduce the effect of an interference if a single congener is used as reference. Other quantitation references and procedures may be used provided that the results produced are as accurate as results produced by the quantitation references and procedures described in this Section.*

10.5.4 Compute and store the response factor (RF) for the labeled compounds, except CB 178. For the Labeled Toxics/LOC/window-defining compounds and the Labeled cleanup standards, use the nearest eluted Labeled injection internal standard as the quantitation reference, as given in Table 2. The Labeled injection internal standards are referenced to CB 178, as shown in Table 2.

11.0 Sample preparation

11.1 Sample preparation involves modifying the physical form of the sample so that the CBs can be extracted efficiently. In general, the samples must be in a liquid form or in the form of finely divided solids in order for efficient extraction to take place. Table 9 lists the phases and suggested quantities for extraction of various sample matrices.

For samples known or expected to contain high levels of the CBs, the smallest sample size representative of the entire sample should be used (see Section 18). For all samples, the blank and IPR/OPR aliquots must be processed through the same steps as the sample to check for contamination and losses in the preparation processes.

11.1.1 For samples that contain particles, percent solids and particle size are determined using the procedures in Sections 11.2 and 11.3, respectively.

11.1.2 Aqueous samples—Because CBs may be bound to suspended particles, the preparation of aqueous samples is dependent on the solids content of the sample.

11.1.2.1 Aqueous samples containing one percent solids or less are prepared per Section 11.4 and extracted directly using one of the extraction techniques in Section 12.2.

11.1.2.2 For aqueous samples containing greater than one percent solids, a sample aliquot sufficient to provide 10 g of dry solids is used, as described in Section 11.5.

11.1.3 Solid samples are prepared using the procedure described in Section 11.5 followed by extraction using the SDS procedure in Section 12.3.

11.1.4 Multi-phase samples—The phase(s) containing the CBs is separated from the non-CB phase using pressure filtration and centrifugation, as described in Section 11.6. The CBs will be in the organic phase in a multi-phase sample in which an organic phase exists.

11.1.5 Procedures for grinding, homogenization, and blending of various sample phases are given in Section 11.7.

11.1.6 Tissue samples—Preparation procedures for fish and other tissues are given in Section 11.8.

11.2 Determination of percent suspended solids

Note: *This aliquot is used for determining the solids content of the sample, not for determination of CBs.*

11.2.1 Aqueous liquids and multi-phase samples consisting of mainly an aqueous phase.

11.2.1.1 Desiccate and weigh a GF/D filter (Section 6.5.3) to three significant figures.

11.2.1.2 Filter 10.0 ±0.02 mL of well-mixed sample through the filter.

11.2.1.3 Dry the filter a minimum of 12 hours at 110 ±5 °C and cool in a desiccator.

11.2.1.4 Calculate percent solids as follows:

$$\% \text{ solids} = \frac{\text{weight of sample aliquot after drying (g)} - \text{weight of filter (g)}}{10 \text{ g}} \times 100$$

11.2.2 Non-aqueous liquids, solids, semi-solid samples, and multi-phase samples in which the main phase is not aqueous; but not tissues.

11.2.2.1 Weigh 5 to 10 g of sample to three significant figures in a tared beaker.

11.2.2.2 Dry a minimum of 12 hours at 110 ±5 °C, and cool in a desiccator.

11.2.2.3 Calculate percent solids as follows:

$$\% \text{ solids} = \frac{\text{weight of sample aliquot after drying}}{\text{weight of sample aliquot before drying}} \times 100$$

11.3 Estimation of particle size

11.3.1 Spread the dried sample from Section 11.2.2.2 on a piece of filter paper or aluminum foil in a fume hood or glove box.

11.3.2 Estimate the size of the particles in the sample. If the size of the largest particles is greater than 1 mm, the particle size must be reduced to 1 mm or less prior to extraction using the procedures in Section 11.7.

11.4 Preparation of aqueous samples containing one percent suspended solids or less.

11.4.1 Aqueous samples containing one percent suspended solids or less are prepared using the procedure below and extracted using the one of the extraction techniques in Section 12.2.

11.4.2 Preparation of sample and QC aliquots

11.4.2.1 Mark the original level of the sample on the sample bottle for reference.
Weigh the sample plus bottle to ± 1 g.

Method 1668A with corrections and changes through August 20, 2003

- 11.4.2.2** Spike 1.0 mL of the Labeled Toxics/LOC/window-defining standard spiking solution (Section 7.12) into the sample bottle. Cap the bottle and mix the sample by careful shaking. Allow the sample to equilibrate for 1 to 2 hours, with occasional shaking.
- 11.4.2.3** For each sample or sample batch (to a maximum of 20 samples) to be extracted during the same 12-hour shift, place two 1.0-L aliquots of reagent water in clean sample bottles or flasks.
- 11.4.2.4** Spike 1.0 mL of the Labeled Toxics/LOC/window-defining standard spiking solution (Section 7.12) into both reagent water aliquots. One of these aliquots will serve as the Method blank.
- 11.4.2.5** Spike 1.0 mL of the Native Toxics/LOC standard spiking solution (Section 7.11) into the remaining reagent water aliquot. This aliquot will serve as the OPR (Section 15.5).
- 11.4.2.6** For extraction using SPE, add 5 mL of methanol to the sample and QC aliquots. Cap and shake the sample and QC aliquots to mix thoroughly, and proceed to Section 12.2 for extraction.

11.5 Preparation of samples containing greater than one percent solids

- 11.5.1** Weigh a well-mixed aliquot of each sample (of the same matrix type) sufficient to provide 10 g of dry solids (based on the solids determination in Section 11.2) into a clean beaker or glass jar.
- 11.5.2** Spike 1.0 mL of the Labeled Toxics/LOC/window-defining standard spiking solution (Section 7.12) into the sample.
- 11.5.3** For each sample or sample batch (to a maximum of 20 samples) to be extracted during the same 12 hour shift, weigh two 10-g aliquots of the appropriate reference matrix (Section 7.6) into clean beakers or glass jars.
- 11.5.4** Spike 1.0 mL of the Labeled Toxics/LOC/window-defining standard spiking solution (Section 7.12) into both reference matrix aliquots. Spike 1.0 mL of the Native Toxics/LOC standard spiking solution (Section 7.11) into one reference matrix aliquot. This aliquot will serve as the OPR (Section 15.5). The other aliquot will serve as the Method blank.
- 11.5.5** Stir or tumble and equilibrate the aliquots for 1 to 2 hours.
- 11.5.6** Decant excess water. If necessary to remove water, filter the sample through a glass-fiber filter and discard the aqueous liquid.
- 11.5.7** If particles >1 mm are present in the sample (as determined in Section 11.3.2), spread the sample on clean aluminum foil in a hood. After the sample is dry, grind to reduce the particle size (Section 11.7).

11.5.8 Extract the sample and QC aliquots using the SDS procedure in Section 12.3.

11.6 Multi-phase samples

11.6.1 Using the percent solids determined in Section 11.2.1 or 11.2.2, determine the volume of sample that will provide 10 g of solids, up to 1 L of sample.

11.6.2 Spike 1.0 mL of the Labeled Toxics/LOC/window-defining standard spiking solution (Section 7.12) into the amount of sample determined in Section 11.6.1, and into the OPR and blank. Spike 1.0 mL of the Native Toxics/LOC standard spiking solution (Section 7.11) into the OPR. Pressure filter the sample, blank, and OPR through Whatman GF/D glass-fiber filter paper (Section 6.5.3). If necessary to separate the phases and/or settle the solids, centrifuge these aliquots prior to filtration.

11.6.3 Discard any aqueous phase (if present). Remove any non-aqueous liquid present and reserve the maximum amount filtered from the sample (Section 11.6.1) or 10 g, whichever is less, for combination with the solid phase (Section 12.3.5).

11.6.4 If particles >1 mm are present in the sample (as determined in Section 11.3.2) and the sample is capable of being dried, spread the sample and QC aliquots on clean aluminum foil in a hood. Observe the precaution in Section 4.8.

11.6.5 After the aliquots are dry or if the sample cannot be dried, reduce the particle size using the procedures in Section 11.7 and extract the reduced-size particles using the SDS procedure in Section 12.3. If particles >1 mm are not present, extract the particles and filter in the sample and QC aliquots directly using the SDS procedure in Section 12.3.

11.7 Sample grinding, homogenization, or blending—Samples with particle sizes greater than 1 mm (as determined in Section 11.3.2) are subjected to grinding, homogenization, or blending. The method of reducing particle size to less than 1 mm is matrix-dependent. In general, hard particles can be reduced by grinding with a mortar and pestle. Softer particles can be reduced by grinding in a Wiley mill or meat grinder, by homogenization, or in a blender.

11.7.1 Each size-reducing preparation procedure on each matrix must be verified by running the tests in Section 9.2 before the procedure is employed routinely.

11.7.2 The grinding, homogenization, or blending procedures must be carried out in a glove box or fume hood to prevent particles from contaminating the work environment.

11.7.3 Grinding—Certain papers and pulps, slurries, and amorphous solids can be ground in a Wiley mill or heavy duty meat grinder. In some cases, reducing the temperature of the sample to freezing or to dry ice or liquid nitrogen temperatures can aid in the grinding process. Grind the sample aliquots from Sections 11.5.7 or 11.6.5 in a clean grinder. Do not allow the sample temperature to exceed 50 °C. Grind the blank and reference matrix aliquots using a clean grinder.

11.7.4 Homogenization or blending—Particles that are not ground effectively, or particles greater than 1 mm in size after grinding, can often be reduced in size by high speed

homogenization or blending. Homogenize and/or blend the particles or filter from Sections 11.5.7 or 11.6.5 for the sample, blank, and OPR aliquots.

11.7.5 Extract the aliquots using the SDS procedure in Section 12.3.

11.8 Fish and other tissues—Prior to processing tissue samples, the laboratory must determine the exact tissue to be analyzed. Common requests for analysis of fish tissue include whole fish-skin on, whole fish-skin removed, edible fish fillets (filleted in the field or by the laboratory), specific organs, and other portions. Once the appropriate tissue has been determined, the sample must be homogenized.

11.8.1 Homogenization

11.8.1.1 Samples are homogenized while still frozen, where practical. If the laboratory must dissect the whole fish to obtain the appropriate tissue for analysis, the unused tissues may be rapidly refrozen and stored in a clean glass jar for subsequent use.

11.8.1.2 Each analysis requires 10 g of tissue (wet weight). Therefore, the laboratory should homogenize at least 20 g of tissue to allow for re-extraction of a second aliquot of the same homogenized sample, if re-analysis is required. When whole fish analysis is necessary, the entire fish is homogenized.

11.8.1.3 Homogenize the sample in a tissue homogenizer (Section 6.3.3) or grind in a meat grinder (Section 6.3.4). Cut tissue too large to feed into the grinder into smaller pieces. To assure homogeneity, grind three times.

11.8.1.4 Transfer approximately 10 g (wet weight) of homogenized tissue to a clean, tared, 400- to 500-mL beaker.

11.8.1.5 Transfer the remaining homogenized tissue to a clean jar with a fluoropolymer-lined lid. Seal the jar and store the tissue at less than -10 °C. Return any tissue that was not homogenized to its original container and store at less than -10 °C.

11.8.2 QC aliquots

11.8.2.1 Prepare a Method blank by adding approximately 1-2 g of the oily liquid reference matrix (Section 7.6.4) to a 400- to 500-mL beaker.

11.8.2.2 Prepare a precision and recovery aliquot by adding 1-2 g of the oily liquid reference matrix (Section 7.6.4) to a separate 400- to 500-mL beaker. Record the weight to the nearest 10 mg. If the initial precision and recovery test is to be performed, use four aliquots; if the ongoing precision and recovery test is to be performed, use a single aliquot.

11.8.3 Spiking

11.8.3.1 Spike 1.0 mL of the Labeled Toxic/LOC/window-defining standard spiking solution (Section 7.12) into the sample, blank, and OPR aliquot.

11.8.3.2 Spike 1.0 mL of the Native Toxic/LOC standard spiking solution (Section 7.11) into the OPR aliquot.

11.8.4 Extract the aliquots using the procedures in Section 12.4.

12.0 Extraction and concentration

12.1 Extraction procedures include: solid-phase (Section 12.2.1), separatory funnel (Section 12.2.2), and continuous liquid/liquid (Section 12.2.3) for aqueous liquids; Soxhlet/Dean-Stark (Section 12.3) for solids and filters; and Soxhlet extraction (Section 12.4) for tissues. Acid/base back-extraction (Section 12.5) is used for initial cleanup of extracts.

Macro-concentration procedures include: rotary evaporation (Section 12.6.1), heating mantle (Section 12.6.2), and Kuderna-Danish (K-D) evaporation (Section 12.6.3). Micro-concentration uses nitrogen evaporation (Section 12.7).

12.2 Extraction of aqueous liquids

12.2.1 Solid-phase extraction of samples containing less than one percent solids

12.2.1.1 Disk preparation

12.2.1.1.1 Remove the test tube from the suction flask (Figure 4). Place an SPE disk on the base of the filter holder and wet with methylene chloride. While holding a GMF 150 filter above the SPE disk with tweezers, wet the filter with methylene chloride and lay the filter on the SPE disk, making sure that air is not trapped between the filter and disk. Clamp the filter and SPE disk between the 1-L glass reservoir and the vacuum filtration flask.

12.2.1.1.2 Rinse the sides of the reservoir with approx 15 mL of methylene chloride using a squeeze bottle or pipet. Apply vacuum momentarily until a few drops appear at the drip tip. Release the vacuum and allow the filter/disk to soak for approx one minute. Apply vacuum and draw all of the methylene chloride through the filter/disk. Repeat the wash step with approx 15 mL of acetone and allow the filter/disk to air dry.

12.2.1.2 Sample extraction

12.2.1.2.1 Pre-wet the disk by adding approx 20 mL of methanol to the reservoir. Pull most of the methanol through the filter/disk, retaining a layer of methanol approx 2 mm thick on the filter.

Do not allow the filter/disk to go dry from this point until the extraction is completed.

- 12.2.1.2.2** Add approx 20 mL of reagent water to the reservoir and pull most through, leaving a layer approx 2 mm thick on the filter/disk.
- 12.2.1.2.3** Allow the sample (Section 11.4.2.6) to stand for 1-2 hours, if necessary, to settle the suspended particles. Decant the clear layer of the sample, the blank (Section 11.4.2.4), or IPR/OPR aliquot (Section 11.4.2.5) into its respective reservoir and turn on the vacuum to begin the extraction. Adjust the vacuum to complete the extraction in no less than 10 minutes. For samples containing a high concentration of particles (suspended solids), the extraction time may be an hour or longer.
- 12.2.1.2.4** Before all of the sample has been pulled through the filter/disk, add approx 50 mL of reagent water to the sample bottle, swirl to suspend the solids (if present), and pour into the reservoir. Pull through the filter/disk. Use additional reagent water rinses until all solids are removed.
- 12.2.1.2.5** Before all of the sample and rinses have been pulled through the filter/disk, rinse the sides of the reservoir with small portions of reagent water.
- 12.2.1.2.6** Partially dry the filter/disk under vacuum for approx 3 minutes.

12.2.1.3 Elution of the filter/disk

- 12.2.1.3.1** Release the vacuum, remove the entire filter/disk/reservoir assembly from the vacuum flask, and empty the flask. Insert a test tube for eluant collection into the flask. The test tube should have sufficient capacity to contain the total volume of the elution solvent (approx 50 mL) and should fit around the drip tip. The drip tip should protrude into the test tube to preclude loss of sample from spattering when vacuum is applied. Reassemble the filter/disk/reservoir assembly on the vacuum flask.
- 12.2.1.3.2** Wet the filter/disk with 4-5 mL of acetone. Allow the acetone to spread evenly across the disk and soak for 15-20 seconds. Pull the acetone through the disk, releasing the vacuum when approx 1 mm thickness remains on the filter.
- 12.2.1.3.3** Rinse the sample bottle with approx 20 mL of methylene chloride and transfer to the reservoir. Pull approx half of the solvent through the filter/disk and release the vacuum. Allow the filter/disk to soak for approx 1 minute. Pull all of the solvent through the disk. Repeat the bottle rinsing and elution step with

another 20 mL of methylene chloride. Pull all of the solvent through the disk.

- 12.2.1.3.4** Release the vacuum, remove the filter/disk/reservoir assembly, and remove the test tube containing the sample solution. Quantitatively transfer the solution to a 250-mL separatory funnel and proceed to Section 12.5 for back-extraction.

12.2.2 Separatory funnel extraction

- 12.2.2.1** Pour the spiked sample (Section 11.4.2.2) into a 2-L separatory funnel. Rinse the bottle or flask twice with 5 mL of reagent water and add these rinses to the separatory funnel.
- 12.2.2.2** Add 60 mL methylene chloride to the empty sample bottle. Seal the bottle and shake 60 seconds to rinse the inner surface. Transfer the solvent to the separatory funnel, and extract the sample by shaking the funnel for 2 minutes with periodic venting. Allow the organic layer to separate from the aqueous phase for a minimum of 10 minutes. If an emulsion forms and is more than one-third the volume of the solvent layer, employ mechanical techniques to complete the phase separation (see note below). Drain the methylene chloride extract through a solvent-rinsed glass funnel approximately one-half full of granular anhydrous sodium sulfate (Section 7.2.1) supported on clean glass-fiber paper into a solvent-rinsed concentration device (Section 12.6).

Note: *If an emulsion forms, the laboratory must employ mechanical techniques to complete the phase separation. The optimum technique depends upon the sample, but may include stirring, filtration through glass wool, use of phase separation paper, centrifugation, use of an ultrasonic bath with ice, addition of NaCl, or other physical methods. Alternatively, solid-phase (Section 12.2.1), CLLE (Section 12.2.3), or other extraction techniques may be used to prevent emulsion formation. Any alternative technique is acceptable so long as the requirements in Section 9.2 are met.*

- 12.2.2.3** Extract the water sample two more times with 60-mL portions of methylene chloride. Drain each portion through the sodium sulfate into the concentrator. After the third extraction, rinse the separatory funnel with at least 20 mL of methylene chloride, and drain this rinse through the sodium sulfate into the concentrator. Repeat this rinse at least twice. Set aside the funnel with sodium sulfate if the extract is to be combined with the extract from the particles.
- 12.2.2.4** Concentrate the extract using one of the macro-concentration procedures in Section 12.6 and proceed to back extraction in Section 12.5.

12.2.3 Continuous liquid/liquid extraction

- 12.2.3.1** Place 100-150 mL methylene chloride in each continuous extractor and 200-300 mL in each distilling flask.

- 12.2.3.2** Pour the sample(s), blank, and QC aliquots into the extractors. Rinse the sample containers with 50-100 mL methylene chloride and add to the respective extractors. Include all solids in the extraction process.
- 12.2.3.3** Begin the extraction by heating the flask until the methylene chloride is boiling. When properly adjusted, 1-2 drops of methylene chloride per second will fall from the condenser tip into the water. Extract for 16-24 hours.
- 12.2.3.4** Remove the distilling flask, estimate and record the volume of extract (to the nearest 100 mL), and pour the contents through a drying column containing 7 to 10 cm of granular anhydrous sodium sulfate into a 500-mL K-D evaporator flask equipped with a 10-mL concentrator tube. Rinse the distilling flask with 30-50 mL of methylene chloride and pour through the drying column. Concentrate and exchange to hexane per Section 12.6 and back extract per Section 12.5.

12.3 SDS extraction of samples containing particles

- 12.3.1** Charge a clean extraction thimble (Section 6.4.2.2) with 5.0 g of 100/200 mesh silica (Section 7.5.1.1) topped with 100 g of quartz sand (Section 7.3.2).

Note: *Do not disturb the silica layer throughout the extraction process.*

- 12.3.2** Place the thimble in a clean extractor. Place 30 to 40 mL of toluene in the receiver and 200 to 250 mL of toluene in the flask.
- 12.3.3** Pre-extract the glassware by heating the flask until the toluene is boiling. When properly adjusted, 1 to 2 drops of toluene will fall per second from the condenser tip into the receiver. Extract the apparatus for a minimum of 3 hours.
- 12.3.4** After pre-extraction, cool and disassemble the apparatus. Rinse the thimble with toluene and allow to air dry.
- 12.3.5** Load the wet sample and/or filter from Sections 11.5.8, 11.6.5, or 11.7.5 and any non-aqueous liquid from Section 11.6.3 into the thimble and manually mix into the sand layer with a clean metal spatula, carefully breaking up any large lumps of sample.
- 12.3.6** Reassemble the pre-extracted SDS apparatus, and add a fresh charge of toluene to the receiver and reflux flask. Apply power to the heating mantle to begin re-refluxing. Adjust the reflux rate to match the rate of percolation through the sand and silica beds until water removal lessens the restriction to toluene flow. Frequently check the apparatus for foaming during the first 2 hours of extraction. If foaming occurs, reduce the reflux rate until foaming subsides.
- 12.3.7** Drain the water from the receiver at 1-2 hours and 8-9 hours, or sooner if the receiver fills with water. Reflux the sample for a total of 16-24 hours. Cool and disassemble the apparatus. Record the total volume of water collected.

- 12.3.8** Remove the distilling flask. Drain the water from the Dean-Stark receiver and add any toluene in the receiver to the extract in the flask.
- 12.3.9** Concentrate the extracts from particles to approximately 10 mL using the rotary evaporator (Section 12.6.1) or heating mantle (Section 12.6.2), transfer to a 250-mL separatory funnel, and proceed with back-extraction (Section 12.5).

12.4 Soxhlet extraction of tissue

Note: This procedure includes determination of the lipid content of the sample (Sections 12.4.8 - 12.4.9), using the same sample extract that is analyzed by GC/MS. Alternatively, a separate sample aliquot may be used for the lipid determination. If a separate aliquot is used, use nitrogen to evaporate the main portion of the sample extract only to the extent necessary to effect the solvent exchange to n-hexane, so that loss of low molecular weight CBs is avoided, i.e., it is not necessary to dry the main portion of the sample to constant weight (Section 12.4.8).

- 12.4.1** Add 30 to 40 g of powdered anhydrous sodium sulfate (Section 7.2.2) to each of the beakers (Section 11.8.4) and mix thoroughly. Cover the beakers with aluminum foil and dry until the mixture becomes a free-flowing powder (30 minutes minimum). Remix prior to extraction to prevent clumping.
- 12.4.2** Assemble and pre-extract the Soxhlet apparatus per Sections 12.3.1-12.3.4, except use methylene chloride for the pre-extraction and rinsing and omit the quartz sand.
- 12.4.3** Reassemble the pre-extracted Soxhlet apparatus and add a fresh charge of methylene chloride to the reflux flask.
- 12.4.4** Transfer the sample/sodium sulfate mixture (Section 12.4.1) to the Soxhlet thimble, and install the thimble in the Soxhlet apparatus.
- 12.4.5** Rinse the beaker with several portions of solvent and add to the thimble. Fill the thimble/receiver with solvent. Extract for 18-24 hours.
- 12.4.6** After extraction, cool and disassemble the apparatus.
- 12.4.7** Quantitatively transfer the extract to a macro-concentration device (Section 12.6), and concentrate to near dryness. Set aside the concentration apparatus for re-use.
- 12.4.8** Complete the removal of the solvent using the nitrogen blowdown procedure (Section 12.7) and a water bath temperature of 60 °C. Weigh the receiver, record the weight, and return the receiver to the blowdown apparatus, concentrating the residue until a constant weight is obtained.
- 12.4.9** Percent lipid determination
- 12.4.9.1** Redissolve the residue in the receiver in hexane and spike 1.0 mL of the Labeled cleanup standard spiking solution (Section 7.13) into the solution.

12.4.9.2 Transfer the residue/hexane to the anthropogenic isolation column (Section 13.6), retaining the boiling chips in the concentration apparatus. Use several rinses to assure that all material is transferred. If necessary, sonicate or heat the receiver slightly to assure that all material is re-dissolved. Allow the receiver to dry. Weigh the receiver and boiling chips.

12.4.9.3 Calculate the lipid content to the nearest three significant figures as follows:

$$\text{Percent lipid} = \frac{\text{Weight of residue (g)}}{\text{Weight of tissue (g)}} \times 100$$

12.4.9.4 The laboratory should determine the lipid content of the blank, IPR, and OPR to assure that the extraction system is working effectively.

12.5 Back-extraction with base and acid

12.5.1 Back-extraction may not be necessary for some samples. For some samples, the presence of color in the extract may indicate that back-extraction is necessary. If back-extraction is not performed, spike 1.0 mL of the Labeled cleanup standard spiking solution (Section 7.13) into the extract and concentrate the extract for cleanup or analysis (Section 12.7). If back-extraction is necessary, spike 1.0 mL of the Labeled cleanup standard spiking solution (Section 7.13) into the separatory funnels containing the sample and QC extracts from Section 12.2.3.4 or 12.3.9.

12.5.2 Partition the extract against 50 mL of potassium hydroxide solution (Section 7.1.1). Shake for 2 minutes with periodic venting into a hood. Remove and discard the aqueous layer. Repeat the base washing until no color is visible in the aqueous layer, to a maximum of four washings. Minimize contact time between the extract and the base to prevent degradation of the CBs. Stronger potassium hydroxide solutions may be employed for back-extraction, provided that the laboratory meets the specifications for labeled compound recovery and demonstrates acceptable performance using the procedure in Section 9.2.

12.5.3 Partition the extract against 50 mL of sodium chloride solution (Section 7.1.4) in the same way as with base. Discard the aqueous layer.

12.5.4 Partition the extract against 50 mL of sulfuric acid (Section 7.1.2) in the same way as with base. Repeat the acid washing until no color is visible in the aqueous layer, to a maximum of four washings.

12.5.5 Repeat the partitioning against sodium chloride solution and discard the aqueous layer.

12.5.6 Pour each extract through a drying column containing 7 to 10 cm of granular anhydrous sodium sulfate (Section 7.2.1). Rinse the separatory funnel with 30 to 50 mL of solvent, and pour through the drying column. Collect each extract in a round-bottom flask. Re-concentrate the sample and QC aliquots per Sections 12.6-12.7, and clean up the samples and QC aliquots per Section 13.

12.6 Macro-concentration—Extracts in toluene are concentrated using a rotary evaporator or a heating mantle; extracts in methylene chloride or hexane are concentrated using a rotary evaporator, heating mantle, or Kuderna-Danish apparatus.

Note: *In the concentration procedures below, the extract must not be allowed to concentrate to dryness because the mono- through tri-chlorobiphenyls may be totally or partially lost.*

12.6.1 Rotary evaporation—Concentrate the extracts in separate round-bottom flasks.

12.6.1.1 Assemble the rotary evaporator according to manufacturer's instructions, and warm the water bath to 45 °C. On a daily basis, pre-clean the rotary evaporator by concentrating 100 mL of clean extraction solvent through the system. Archive both the concentrated solvent and the solvent in the catch flask for a contamination check if necessary. Between samples, three 2- to 3-mL aliquots of solvent should be rinsed down the feed tube into a waste beaker.

12.6.1.2 Attach the round-bottom flask containing the sample extract to the rotary evaporator. Slowly apply vacuum to the system, and begin rotating the sample flask.

12.6.1.3 Lower the flask into the water bath, and adjust the speed of rotation and the temperature as required to complete concentration in 15 to 20 minutes. At the proper rate of concentration, the flow of solvent into the receiving flask will be steady, but no bumping or visible boiling of the extract will occur.

Note: *If the rate of concentration is too fast, analyte loss may occur.*

12.6.1.4 When the liquid in the concentration flask has reached an apparent volume of approximately 2 mL, remove the flask from the water bath and stop the rotation. Slowly and carefully admit air into the system. Be sure not to open the valve so quickly that the sample is blown out of the flask. Rinse the feed tube with approximately 2 mL of solvent.

12.6.1.5 Proceed to Section 12.6.4 for preparation for back-extraction or micro-concentration and solvent exchange.

12.6.2 Heating mantle—Concentrate the extracts in separate round-bottom flasks.

12.6.2.1 Add one or two clean boiling chips to the round-bottom flask, and attach a three-ball macro Snyder column. Prewet the column by adding approximately 1 mL of solvent through the top. Place the round-bottom flask in a heating mantle, and apply heat as required to complete the concentration in 15 to 20 minutes. At the proper rate of distillation, the balls of the column will actively chatter, but the chambers will not flood.

12.6.2.2 When the liquid has reached an apparent volume of approximately 10 mL, remove the round-bottom flask from the heating mantle and allow the solvent

to drain and cool for at least 10 minutes. Remove the Snyder column and rinse the glass joint into the receiver with small portions of solvent.

12.6.2.3 Proceed to Section 12.6.4 for preparation for back-extraction or micro-concentration and solvent exchange.

12.6.3 Kuderna-Danish (K-D)—Concentrate the extracts in separate 500-mL K-D flasks equipped with 10-mL concentrator tubes. The K-D technique is used for solvents such as methylene chloride and hexane. Toluene is difficult to concentrate using the K-D technique unless a water bath fed by a steam generator is used.

12.6.3.1 Add 1 to 2 clean boiling chips to the receiver. Attach a three-ball macro Snyder column. Prewet the column by adding approximately 1 mL of solvent through the top. Place the K-D apparatus in a hot water bath so that the entire lower rounded surface of the flask is bathed with steam.

12.6.3.2 Adjust the vertical position of the apparatus and the water temperature as required to complete the concentration in 15 to 20 minutes. At the proper rate of distillation, the balls of the column will actively chatter but the chambers will not flood.

12.6.3.3 When the liquid has reached an apparent volume of 1 mL, remove the K-D apparatus from the bath and allow the solvent to drain and cool for at least 10 minutes. Remove the Snyder column and rinse the flask and its lower joint into the concentrator tube with 1 to 2 mL of solvent. A 5-mL syringe is recommended for this operation.

12.6.3.4 Remove the three-ball Snyder column, add a fresh boiling chip, and attach a two ball micro Snyder column to the concentrator tube. Prewet the column by adding approximately 0.5 mL of solvent through the top. Place the apparatus in the hot water bath.

12.6.3.5 Adjust the vertical position and the water temperature as required to complete the concentration in 5 to 10 minutes. At the proper rate of distillation, the balls of the column will actively chatter but the chambers will not flood.

12.6.3.6 When the liquid reaches an apparent volume of 0.5 mL, remove the apparatus from the water bath and allow to drain and cool for at least 10 minutes.

12.6.3.7 Proceed to 12.6.4 for preparation for back-extraction or micro-concentration and solvent exchange.

12.6.4 Preparation for back-extraction or micro-concentration and solvent exchange

12.6.4.1 For back-extraction (Section 12.5), transfer the extract to a 250-mL separatory funnel. Rinse the concentration vessel with small portions of hexane, adjust the hexane volume in the separatory funnel to 10 to 20 mL, and proceed to back-extraction (Section 12.5).

12.6.4.2 For determination of the weight of residue in the extract, or for clean-up procedures other than back-extraction, transfer the extract to a blowdown vial using 2-3 rinses of solvent. Proceed with micro-concentration and solvent exchange (Section 12.7).

12.7 Micro-concentration and solvent exchange

12.7.1 Extracts to be subjected to GPC cleanup are exchanged into methylene chloride. Extracts to be cleaned up using silica gel, carbon, Florisil, and/or HPLC are exchanged into hexane.

12.7.2 Transfer the vial containing the sample extract to a nitrogen evaporation device. Adjust the flow of nitrogen so that the surface of the solvent is just visibly disturbed.

Note: *A large vortex in the solvent may cause analyte loss.*

12.7.3 Lower the vial into a 45 °C water bath and continue concentrating.

12.7.3.1 If the extract or an aliquot of the extract is to be concentrated to dryness for weight determination (Sections 12.4.8 and 13.6.4), blow dry until a constant weight is obtained.

12.7.3.2 If the extract is to be concentrated for injection into the GC/MS or the solvent is to be exchanged for extract cleanup, proceed as follows:

12.7.4 When the volume of the liquid is approximately 100 µL, add 2 to 3 mL of the desired solvent (methylene chloride for GPC and HPLC, or hexane for the other cleanups) and continue concentration to approximately 100 µL. Repeat the addition of solvent and concentrate once more.

12.7.5 If the extract is to be cleaned up by GPC, adjust the volume of the extract to 5.0 mL with methylene chloride. If the extract is to be cleaned up by HPLC, concentrate the extract to 1.0 mL. Proceed with GPC or HPLC cleanup (Section 13.2 or 13.5, respectively).

12.7.6 If the extract is to be cleaned up by column chromatography (silica gel, Caropak/Celite, or Florisil), bring the final volume to 1.0 mL with hexane. Proceed with column cleanup (Sections 13.3, 13.4, or 13.7).

12.7.7 If the extract is to be concentrated for injection into the GC/MS (Section 14), quantitatively transfer the extract to a 0.3-mL conical vial for final concentration, rinsing the larger vial with hexane and adding the rinse to the conical vial. Reduce the volume to approximately 100 µL. Add 20 µL of nonane to the vial, and evaporate the solvent to the level of the nonane. Seal the vial and label with the sample number. Store in the dark at room temperature until ready for GC/MS analysis. If GC/MS analysis will not be performed on the same day, store the vial at less than -10 °C.

13.0 Extract cleanup

13.1 Cleanup may not be necessary for relatively clean samples (e.g., treated effluents, groundwater, drinking water). If particular circumstances require the use of a cleanup procedure, the laboratory may use any or all of the procedures below or any other appropriate procedure. Before using a cleanup procedure, the laboratory must demonstrate that the requirements of Section 9.2 can be met using the cleanup procedure.

13.1.1 Gel permeation chromatography (Section 13.2) removes high molecular weight interferences that cause GC column performance to degrade. It should be used for all soil and sediment extracts. It may be used for water extracts that are expected to contain high molecular weight organic compounds (e.g., polymeric materials, humic acids). It should also be used for tissue extracts after initial cleanup on the anthropogenic isolation column (Section 13.6).

13.1.2 Acid, neutral, and basic silica gel (Section 13.3) and Florisil (Section 13.7) are used to remove non-polar and polar interferences.

13.1.3 Carbowax/Celite (Section 13.4) can be used to separate CBs 77, 126, and 169 from the mono- and di- ortho-substituted CBs, if desired.

13.1.4 HPLC (Section 13.5) is used to provide specificity for certain congeners and congener groups.

13.1.5 The anthropogenic isolation column (Section 13.6) is used for removal of lipids from tissue samples.

13.2 Gel permeation chromatography (GPC)

13.2.1 Column packing

13.2.1.1 Place 70 to 75 g of SX-3 Bio-beads (Section 6.7.1.1) in a 400- to 500-mL beaker.

13.2.1.2 Cover the beads with methylene chloride and allow to swell overnight (a minimum of 12 hours).

13.2.1.3 Transfer the swelled beads to the column (Section 6.7.1.1) and pump solvent through the column, from bottom to top, at 4.5 to 5.5 mL/minute prior to connecting the column to the detector.

13.2.1.4 After purging the column with solvent for 1 to 2 hours, adjust the column head pressure to 7 to 10 psig and purge for 4 to 5 hours to remove air. Maintain a head pressure of 7 to 10 psig. Connect the column to the detector (Section 6.7.1.4).

13.2.2 Column calibration

- 13.2.2.1** Load 5 mL of the GPC calibration solution (Section 7.4) into the sample loop.
 - 13.2.2.2** Inject the GPC calibration solution and record the signal from the detector. The elution pattern will be corn oil, BEHP, methoxychlor, perylene, and sulfur.
 - 13.2.2.3** Set the "dump time" to allow >85% removal of BEHP and >85% collection of methoxychlor.
 - 13.2.2.4** Set the "collect time" to the time of the sulfur peak maximum.
 - 13.2.2.5** Verify calibration with the GPC calibration solution after every 20 extracts. Calibration is verified if the recovery of the methoxychlor is greater than 85%. If calibration is not verified, the system must be recalibrated using the GPC calibration solution, and the previous sample batch must be re-extracted and cleaned up using the calibrated GPC system.
- 13.2.3** Extract cleanup—GPC requires that the column not be overloaded. The column specified in this Method is designed to handle a maximum of 0.5 g of material from an aqueous, soil, or mixed-phase sample in a 5-mL extract, and has been shown to handle 1.5 g of lipid from a tissue sample in a 5-mL extract. If the extract is known or expected to contain more than these amounts, the extract is split into aliquots for GPC, and the aliquots are combined after elution from the column. The residue content of the extract may be obtained gravimetrically by evaporating the solvent from a 50- μ L aliquot.
- 13.2.3.1** Filter the extract or load through the filter holder (Section 6.7.1.3) to remove particles. Load the 5.0-mL extract onto the column.
 - 13.2.3.2** Elute the extract using the calibration data determined in Section 13.2.2. Collect the eluate in a clean 400- to 500-mL beaker. Allow the system to rinse for additional 10 minutes before injecting the next sample.
 - 13.2.3.3** Rinse the sample loading tube thoroughly with methylene chloride between extracts to prepare for the next sample.
 - 13.2.3.4** If an extract is encountered that could overload the GPC column to the extent that carry-over could occur, a 5.0-mL methylene chloride blank must be run through the system to check for carry-over.
 - 13.2.3.5** Concentrate the eluate per Sections 12.6 and 12.7 for further cleanup or injection into the GC/MS.

13.3 Silica gel cleanup

- 13.3.1** Place a glass-wool plug in a 15-mm ID chromatography column (Section 6.7.4.2). Pack the column bottom to top with: 1 g silica gel (Section 7.5.1.1), 4 g basic silica gel (Section 7.5.1.3), 1 g silica gel, 8 g acid silica gel (Section 7.5.1.2), 2 g silica gel, and 4

g granular anhydrous sodium sulfate (Section 7.2.1). Tap the column to settle the adsorbents.

- 13.3.2** Pre-elute the column with 50 to 100 mL of hexane. Close the stopcock when the hexane is within 1 mm of the sodium sulfate. Discard the eluate. Check the column for channeling. If channeling is present, discard the column and prepare another.
- 13.3.3** Apply the concentrated extract to the column. Open the stopcock until the extract is within 1 mm of the sodium sulfate.
- 13.3.4** Rinse the receiver twice with 1-mL portions of hexane, and apply separately to the column. Elute the CBs with 25 mL of hexane and collect the eluate.
- 13.3.5** Concentrate the eluate per Section 12.6 and 12.7 for further cleanup or injection into the HPLC or GC/MS.
- 13.3.6** For extracts of samples known to contain large quantities of other organic compounds, it may be advisable to increase the capacity of the silica gel column. This may be accomplished by increasing the strengths of the acid and basic silica gels. The acid silica gel (Section 7.5.1.2) may be increased in strength to as much as 40% w/w (6.7 g sulfuric acid added to 10 g silica gel). The basic silica gel (Section 7.5.1.3) may be increased in strength to as much as 33% w/w (50 mL 1N NaOH added to 100 g silica gel), or the potassium silicate (Section 7.5.1.4) may be used.

Note: The use of stronger acid silica gel (44% w/w) may lead to charring of organic compounds in some extracts. The charred material may retain some of the analytes and lead to lower recoveries of the CBs. Increasing the strengths of the acid and basic silica gel may also require different volumes of hexane than those specified above to elute the analytes from the column. The performance of the Method after such modifications must be verified by the procedure in Section 9.2.

13.4 Carbon column (Reference 17)

- 13.4.1** Cut both ends from a 50-mL disposable serological pipet (Section 6.7.3.2) to produce a 20-cm column. Fire-polish both ends and flare both ends if desired. Insert a glass-wool plug at one end, and pack the column with 3.6 g of Carboapak/Celite (Section 7.5.2.3) to form an adsorbent bed 20 cm long. Insert a glass-wool plug on top of the bed to hold the adsorbent in place.
- 13.4.2** Pre-elute the column with 20 mL each in succession of toluene, methylene chloride, and hexane.
- 13.4.3** When the solvent is within 1 mm of the column packing, apply the n-hexane sample extract to the column. Rinse the sample container twice with 1-mL portions of hexane and apply separately to the column. Apply 2 mL of hexane to complete the transfer.
- 13.4.4** Elute the column with 25 mL of n-hexane and collect the eluate. This fraction will contain the mono- and di-ortho CBs. If carbon particles are present in the eluate, filter through glass-fiber filter paper.

- 13.4.5** Elute the column with 15 mL of methanol and discard the eluate. The fraction discarded will contain residual lipids and other potential interferents, if present.
- 13.4.6** Elute the column with 15 mL of toluene and collect the eluate. This fraction will contain CBs 77, 126, and 169. If carbon particles are present in the eluate, filter through glass-fiber filter paper.
- 13.4.7** Concentrate the fractions per Section 12.6 and 12.7 for further cleanup or injection into the HPLC or GC/MS.

13.5 HPLC (References 4 and 18)

13.5.1 Column calibration

- 13.5.1.1** Prepare a calibration standard containing the Toxics and other congeners of interest at the concentrations of the stock solution in Table 3, or at a concentration appropriate to the response of the detector.
- 13.5.1.2** Inject the calibration standard into the HPLC and record the signal from the detector. Collect the eluant for reuse. Elution will be in the order of the di-ortho, mono-ortho, and non-ortho congeners.
- 13.5.1.3** Establish the collection time for the congeners of interest. Following calibration, flush the injection system with solvent to ensure that residual CBs are removed from the system.
- 13.5.1.4** Verify the calibration with the calibration solution after every 20 extracts. Calibration is verified if the recovery of the CBs is 75 to 125% compared to the calibration (Section 13.5.1.1). If calibration is not verified, the system must be recalibrated using the calibration solution, and the previous 20 samples must be re-extracted and cleaned up using the calibrated system.

13.5.2 Extract cleanup—HPLC requires that the column not be overloaded. The column specified in this Method is designed to handle a maximum of 5-50 µg of a given CB, depending on the congener (Reference 18). If the amount of material in the extract will overload the column, split the extract into fractions and combine the fractions after elution from the column.

- 13.5.2.1** Rinse the sides of the vial containing the sample and adjust to the volume required for the sample loop for injection.
- 13.5.2.2** Inject the sample extract into the HPLC.
- 13.5.2.3** Elute the extract using the calibration data determined in Section 13.5.1. Collect the fraction(s) in clean 20-mL concentrator tubes.
- 13.5.2.4** If an extract containing greater than 500 µg of total CBs is encountered, a blank must be run through the system to check for carry-over.

13.5.2.5 Concentrate the eluate per Section 12.7 for injection into the GC/MS.

13.6 Anthropogenic isolation column (Reference 3)—Used for removal of lipids from tissue extracts

13.6.1 Prepare the column as given in Section 7.5.3.

13.6.2 Pre-elute the column with 100 mL of hexane. Drain the hexane layer to the top of the column, but do not expose the sodium sulfate.

13.6.3 Load the sample and rinses (Section 12.4.9.2) onto the column by draining each portion to the top of the bed. Elute the CBs from the column into the apparatus used for concentration (Section 12.4.7) using 200 mL of hexane.

13.6.4 Remove a small portion (e.g, 50 μ L) of the extract for determination of residue content. Estimate the percent of the total that this portion represents. Concentrate the small portion to constant weight per Section 12.7.3.1. Calculate the total amount of residue in the extract. If more than 500 mg of material remains, repeat the cleanup using a fresh anthropogenic isolation column.

13.6.5 If necessary, exchange the extract to a solvent suitable for the additional cleanups to be used (Section 13.2-13.5 and 13.7).

13.6.6 Clean up the extract using the procedures in Sections 13.2-13.5 and 13.7. GPC (Section 13.2) and Florisil (Section 13.7) are recommended as minimum additional cleanup steps.

13.6.7 Following cleanup, concentrate the extract to 20 μ L as described in Section 12.7 and proceed with the analysis in Section 14.

13.7 Florisil cleanup (Reference 19)

13.7.1 Begin to drain the n-hexane from the column (Section 7.5.4.1.2). Adjust the flow rate of eluant to 4.5-5.0 mL/min.

13.7.2 When the n-hexane is within 1 mm of the sodium sulfate, apply the sample extract (in hexane) to the column. Rinse the sample container twice with 1-mL portions of hexane and apply to the column.

13.7.3 Elute the mono-ortho and di-ortho CBs with approx 165 mL of n-hexane and collect the eluate. Elute the non-ortho co-planar CBs with approx 100 mL of 6% ether:hexane and collect the eluate. The exact volumes of solvents will need to be determined for each batch of Florisil. If the mono/di-ortho CBs are not to be separated from the non-ortho co-planar CBs, elute all CBs with 6% ether:hexane.

13.7.4 Concentrate the eluate(s) per Sections 12.6-12.7 for further cleanup or for injection into the HPLC or GC/MS.

14.0 HRGC/HRMS analysis

- 14.1** Establish the operating conditions given in Section 10.1.
- 14.2** Add 2 μL of the labeled injection internal standard spiking solution (Section 7.14) to the 20 μL sample extract immediately prior to injection to minimize the possibility of loss by evaporation, adsorption, or reaction. If an extract is to be reanalyzed and evaporation has occurred, do not add more labeled injection internal standard spiking solution. Rather, bring the extract back to its previous volume (e.g., 19 μL) with pure nonane (18 μL if 2 μL injections are used).
- 14.3** Inject 1.0 or 2.0 μL of the concentrated extract containing the Labeled injection internal standards using on-column or splitless injection. The volume injected must be identical to the volume used for calibration (Section 10.3).
- 14.3.1** Start the GC column initial isothermal hold upon injection. Start MS data collection after the solvent peak elutes.
- 14.3.2** Monitor the exact m/z's at each LOC throughout the LOC retention time window. Where warranted, monitor m/z's associated with congeners at higher levels of chlorination to assure that fragments are not interfering with the m/z's for congeners at lower levels of chlorination. Also where warranted, monitor m/z's associated with interferents expected to be present.
- 14.3.3** Stop data collection after $^{13}\text{C}_{12}$ -DeCB has eluted. Return the column to the initial temperature for analysis of the next extract or standard.

15.0 System and laboratory performance

- 15.1** At the beginning of each 12-hour shift during which analyses are performed, GC/MS system performance and calibration are verified for all native CBs and labeled compounds. For these tests, analysis of the CS-3 calibration verification (VER) standard (Section 7.10.1 and Table 5) and the diluted combined 209 congener solution (Section 7.10.2.2 and Table 5) must be used to verify all performance criteria. Adjustment and/or recalibration (Section 10) must be performed until all performance criteria are met. Only after all performance criteria are met may samples, blanks, IPRs, and OPRs be analyzed.
- 15.2** MS resolution—Static resolving power checks must be performed at the beginning and at the end of each shift per Sections 10.2.1. If analyses are performed on successive shifts, only the beginning of shift static resolving power check is required. If the requirement in Section 10.2.1 cannot be met, the problem must be corrected before analyses can proceed. If any of the samples in the previous shift may be affected by poor resolution, those samples must be re-analyzed.
- 15.3** Calibration verification
- 15.3.1** Inject the VER (CS-3) standard using the procedure in Section 14.
- 15.3.2** The m/z abundance ratios for all CBs must be within the limits in Table 8; otherwise, the mass spectrometer must be adjusted until the m/z abundance ratios fall within the

limits specified when the verification test is repeated. If the adjustment alters the resolution of the mass spectrometer, resolution must be verified (Section 10.2.1) prior to repeat of the verification test.

- 15.3.3** The GC peak representing each native CB and labeled compound in the VER standard must be present with a S/N of at least 10; otherwise, the mass spectrometer must be adjusted and the verification test repeated.
- 15.3.4** Compute the concentration of the Toxics/LOC CBs by isotope dilution (Section 17.1). These concentrations are computed based on the calibration data in Section 10.
- 15.3.5** For each compound, compare the concentration with the calibration verification limit in Table 6. If all compounds meet the acceptance criteria, calibration has been verified and analysis of standards and sample extracts may proceed. If, however, any compound fails its respective limit, the measurement system is not performing properly. In this event, prepare a fresh calibration standard or correct the problem and repeat the resolution (Section 15.2) and verification (Section 15.3) tests, or recalibrate (Section 10). If recalibration is required, recalibration for the 209 congeners (Section 10.5) must also be performed.

15.4 Retention times and GC resolution

15.4.1 Retention times.

- 15.4.1.1** Absolute—The absolute retention times of the Labeled Toxics/LOC/window defining standard congeners (Section 7.12) in the verification test (Section 15.3) must be within ± 15 seconds of the respective retention times in the calibration or, if an alternate column or column system is employed, within ± 15 seconds of the respective retention times in the calibration for the alternate column or column system (Section 6.9.1.2).
- 15.4.1.2** Relative—The relative retention times of native CBs and labeled compounds in the verification test (Section 15.3) must be within their respective RRT limits in Table 2 or, if an alternate column or column system is employed, within their respective RRT limits for the alternate column or column system (Section 6.9.1.2).
- 15.4.1.3** If the absolute or relative retention time of any compound is not within the limits specified, the GC is not performing properly. In this event, adjust the GC and repeat the verification test (Section 15.3) or recalibrate (Section 10), or replace the GC column and either verify calibration or recalibrate.

15.4.2 GC resolution and minimum analysis time

- 15.4.2.1** As a final step in calibration verification, inject the Diluted combined 209 congener solution (Section 7.10.2.2 and Table 5).

15.4.2.2 The resolution and minimum analysis time specifications in Sections 6.9.1.1.2 and 6.9.1.1.1, respectively, must be met for the SPB-octyl column or, if an alternate column or column system is employed, must be met as specified for the alternate column or column system (Section 6.9.1.2). If these specifications are not met, the GC analysis conditions must be adjusted until the specifications are met, or the column must be replaced and the calibration verification tests repeated Sections 15.4.1 through 15.4.2.2), or the system must be recalibrated (Section 10).

15.4.2.3 After the resolution and minimum analysis time specifications are met, update the retention times, relative retention times, and response factors for the all congeners except the Toxics and LOC CBs. For the Toxics and LOC CBs, the multi-point calibration data must be used (see Section 10.4 and 15.3).

15.5 Ongoing precision and recovery

15.5.1 Analyze the extract of the ongoing precision and recovery (OPR) aliquot (Section 11.4.2.5, 11.5.4, 11.6.2, or 11.8.3.2) prior to analysis of samples from the same batch.

15.5.2 Compute the percent recovery of the Toxics/LOC CBs by isotope dilution (Section 10.4). Compute the percent recovery of each labeled compound by the internal standard method (Section 10.5).

15.5.3 For the Toxics/LOC CBs and labeled compounds, compare the recovery to the OPR limits given in Table 6. If all compounds meet the acceptance criteria, system performance is acceptable and analysis of blanks and samples may proceed. If, however, any individual concentration falls outside of the range given, the extraction/concentration processes are not being performed properly for that compound. In this event, correct the problem, re-prepare, extract, and clean up the sample batch and repeat the ongoing precision and recovery test (Section 15.5).

15.5.4 If desired, add results that pass the specifications in Section 15.5.3 to initial and previous ongoing data for each compound in each matrix. Update QC charts to form a graphic representation of continued laboratory performance. Develop a statement of laboratory accuracy for each congener in each matrix type by calculating the average percent recovery (R) and the standard deviation of percent recovery (S_R). Express the accuracy as a recovery interval from $R - 2S_R$ to $R + 2S_R$. For example, if $R = 95\%$ and $S_R = 5\%$, the accuracy is 85 to 105%.

15.6 Blank—Analyze the Method blank extracted with each sample batch immediately following analysis of the OPR aliquot to demonstrate freedom from contamination and freedom from carryover from the OPR analysis. If CBs will be carried from the OPR into the Method blank, analyze one or more aliquots of solvent between the OPR and the Method blank. The results of the analysis of the blank must meet the specifications in Section 9.5.2 before sample analyses may proceed.

16.0 Qualitative determination

A CB or labeled compound is identified in a standard, blank, or sample when all of the criteria in Sections 16.1 through 16.4 are met.

- 16.1 The signals for the two exact m/z's in Table 7 must be present and must maximize within the same two scans.
- 16.2 The signal-to-noise ratio (S/N) for the GC peak at each exact m/z must be greater than or equal to 2.5 for each CB detected in a sample extract, and greater than or equal to 10 for all CBs in the calibration and verification standards (Sections 10.3.3 and 15.3.3).
- 16.3 The ratio of the integrated areas of the two exact m/z's specified in Table 7 must be within the limit in Table 8, or within ± 15 percent of the ratio in the midpoint (CS-3) calibration or calibration verification (VER), whichever is most recent.
- 16.4 The relative retention time of the peak for a CB must be within the RRT QC limits specified in Table 2 or within similar limits developed from calibration data (Section 10.1.2)]. If an alternate column or column system is employed, the RRT for the CB must be within its respective RRT QC limits for the alternate column or column system (Section 6.9.1.2).

Note: For native CBs determined by internal standard quantitation, a given CB congener may fall within more than RT window and be mis-identified unless the RRT windows are made very narrow, as in Table 2. Therefore, consistency of the RT and RRT with other congeners and the labeled compounds may be required for rigorous congener identification. Retention time regression analysis may aid in this identification.

- 16.5 Because of congener overlap and the potential for interfering substances, it is possible that all of the identification criteria (Sections 16.1-16.4) may not be met. It is also possible that loss of one or more chlorines from a highly chlorinated congener may inflate or produce a false concentration for a less-chlorinated congener that elutes at the same retention time (see Section 18.5). If identification is ambiguous, an experienced spectrometrist (Section 1.4) must determine the presence or absence of the congener.
- 16.6 If the criteria for identification in Sections 16.1-16.5 are not met, the CB has not been identified and the result for that congener may not be reported or used for permitting or regulatory compliance purposes. If interferences preclude identification, a new aliquot of sample must be extracted, further cleaned up, and analyzed.

17.0 Quantitative determination

17.1 Isotope dilution quantitation

- 17.1.1 By adding a known amount of the Labeled Toxics/LOC/window-defining compounds to every sample prior to extraction, correction for recovery of the CB can be made because the native compound and its labeled analog exhibit similar effects upon extraction, concentration, and gas chromatography. Relative responses (RRs) are used

in conjunction with the calibration data in Section 10.4 to determine concentrations in the final extract, so long as labeled compound spiking levels are constant.

- 17.1.2** Compute the concentrations in the extract of the Native Toxics/LOC CBs using the RRs from the calibration data (Section 10.4) and following equation:

$$C_{ex} \text{ (ng/mL)} = \frac{(A1_n + A2_n) C_l}{(A1_l + A2_l) RR}$$

Where:

C_{ex} = The concentration of the PCB in the extract, and the other terms are as defined in Section 10.5.1

17.2 Internal standard quantitation and labeled compound recovery

- 17.2.1** Compute the concentrations in the extract of the native compounds other than those in the Native Toxics/LOC standard, in the Labeled cleanup standard, and in the Labeled injection internal standard (except for labeled CB 178) using the response factors determined from the calibration data (Section 10.5) and the following equation:

$$C_{ex} \text{ (ng/mL)} = \frac{(A1_s + A2_s) C_{is}}{(A1_{is} + A2_{is}) RF}$$

Where:

C_{ex} = The concentration of the labeled compound in the extract, and the others terms are as defined in Section 10.6.1.

- 17.2.2** Using the concentration in the extract determined above, compute the percent recovery of the Labeled Toxics/LOC/window-defining CBs and the Labeled cleanup standard CBs using the following equation:

$$\text{Recovery (\%)} = \frac{\text{Concentration found (ng/mL)}}{\text{Concentration spiked (ng/mL)}} \times 100$$

- 17.3** The concentration of a native CB in the solid phase of the sample is computed using the concentration of the compound in the extract and the weight of the solids (Section 11.2.2.3), as follows:

$$\text{Concentration in solid (ng/kg)} = \frac{(C_{ex} \times V_{ex})}{W_s}$$

Where:

C_{ex} = The concentration of the compound in the extract.

V_{ex} = The extract volume in mL.

W_s = The sample weight (dry weight) in kg.

- 17.4** The concentration of a native CB in the aqueous phase of the sample is computed using the concentration of the compound in the extract and the volume of water extracted (Section 11.4), as follows:

$$\text{Concentration in aqueous phase (pg/L)} = 1000 \times \frac{(C_{ex} \times V_{ex})}{V_s}$$

Where:

- C_{ex} = The concentration of the compound in the extract.
 V_{ex} = The extract volume in mL.
 V_s = The sample volume in liters.

- 17.5** If the SICP area at either quantitation m/z for any congener exceeds the calibration range of the system, dilute the sample extract by the factor necessary to bring the concentration within the calibration range, adjust the concentration of the Labeled injection internal standard to 100 pg/ μ L in the extract, and analyze an aliquot of this diluted extract. If the CBs cannot be measured reliably by isotope dilution, dilute and analyze an aqueous sample or analyze a smaller portion of a soil, tissue, or mixed-phase sample. Adjust the CB congener concentrations, detection limits, and minimum levels to account for the dilution.
- 17.6** Reporting of results—Results are reported to three significant figures for the CBs and labeled compounds found in all standards, blanks, and samples.

17.6.1 Reporting units and levels

17.6.1.1 Aqueous samples—Report results in pg/L (parts-per-quadrillion).

17.6.1.2 Samples containing greater than 1% solids (soils, sediments, filter cake, compost)—Report results in ng/kg based on the dry weight of the sample. Report the percent solids so that the result may be converted to aqueous units.

17.6.1.3 Tissues—Report results in ng/kg of wet tissue, not on the basis of the lipid content of the tissue. Report the percent lipid content, so that the data user can calculate the concentration on a lipid basis if desired.

17.6.1.4 Reporting level

17.6.1.4.1 Report results above the minimum level of quantitation (ML) for analyses of blanks, standards, and samples. The estimated minimum levels (EMLs) in Table 2 are based on common laboratory contamination levels. A laboratory may establish an ML for a CB lower than the EMLs in Table 2. MLs may be established as low as the lowest calibration point (Table 5) provided that the concentration of the congener in a minimum of 10 blanks for a sample medium (e.g., water, soil, sludge, tissue) is significantly below the EML in Table 2. Significant means that the ML for the congener is no less than 2 standard deviations above the average (mean) level in the minimum of 10 blanks (Reference 20). The blanks must be analyzed during the

same period that samples are analyzed, ideally over an approximately 1-month period.

17.6.1.4.2 Standards (VER, IPR, OPR) and samples—Report the result for each congener at or above the ML (or EML Table 2) to 3 significant figures. Report results below the ML (or EML) as <ML (where ML is the concentration at the ML) or as required by the regulatory authority or permit.

17.6.1.4.3 Blanks—Report results above the ML (or EML) to 3 significant figures. Report results below the ML but above the MDL (or EMDL) to 2 significant figures. Report results below the MDL as <MDL (where MDL is the concentration at the MDL) or as required by the regulatory authority or permit.

17.6.1.4.4 Blank correction—Blank-corrected results may be reported in addition to reporting of separate results for samples (Section 17.6.1.4.1) and blanks (Section 17.6.1.4.2). The recommended procedure for blank correction (Reference 20) is that a result is significantly above the blank level, and the level in the blank may be subtracted, if the result is 2 standard deviations above the mean (average) of results of analyses of 10 or more blanks for a sample medium.

17.6.2 Results for a CB in a sample that has been diluted are reported at the least dilute level at which the area at the quantitation m/z is within the calibration range (Section 17.5).

17.6.3 For a CB having a labeled analog, report results at the least dilute level at which the area at the quantitation m/z is within the calibration range (Section 17.5) and the labeled compound recovery is within the normal range for the Method (Section 9.3 and Table 6).

17.6.4 If requested, the total concentration of all congeners at a given level of chlorination (homolog; i.e., total TrCB, total PeCB, total HxCB) may be reported by summing the concentrations of all congeners identified at that LOC, including both the Toxics and other congeners. Also if requested, total CBs may be reported by summing all congeners identified at all LOCs.

18.0 Analysis of complex samples

18.1 Some samples may contain high levels (>10 ng/L; >1000 ng/kg) of the compounds of interest, interfering compounds, and/or polymeric materials. Some extracts may not concentrate to 20 μ L (Section 12.7); others may overload the GC column and/or mass spectrometer. Fragment ions from congeners at higher levels of chlorination may interfere with determination of congeners at lower levels of chlorination.

18.2 Analyze a smaller aliquot of the sample (Section 17.5) when the extract will not concentrate to 20 μ L after all cleanup procedures have been exhausted. If a smaller aliquot of soils or mixed-phase samples is analyzed, attempt to assure that the sample is representative.

- 18.3** Perform integration of peak areas and calculate concentrations manually when interferences preclude computerized calculations.
- 18.4** Several laboratories have reported that backgrounds of many of the CB congeners are difficult to eliminate, and that these backgrounds can interfere with the determination of the CBs in environmental samples. Backgrounds of Toxics with congener numbers 105, 114, 118, 123, 156, 157, and 167 are common. The effects of contamination on results for these congeners should be understood in order to make a reliable determination.
- 18.5** Interferences may pose a problem in the determination of congeners 81, 123, 126, and 169 in some environmental samples. Loss of one or more chlorines from a highly chlorinated congener may inflate or produce a false concentration for a less-chlorinated congener that elutes at the same retention time. If, upon inspection of the chromatogram, the possibility of interferences is evident (e.g., high concentrations of fragments from loss of one or two chlorines from higher chlorinated closely eluting congeners), carbon column fractionation (Section 13.4) and analysis is recommended.
- 18.6** Recovery of labeled compounds—In most samples, recoveries of the labeled compounds will be similar to those from reagent water or from the alternate matrix (Section 7.6).
- 18.6.1** If the recovery of any of the labeled compounds is outside of the normal range (Table 6), a diluted sample must be analyzed (Section 17.5).
- 18.6.2** If the recovery of any of the labeled compounds in the diluted sample is outside of normal range, the calibration verification standard (Section 7.10.1 and Table 5) must be analyzed and calibration verified (Section 15.3).
- 18.6.3** If the calibration cannot be verified, a new calibration must be performed and the original sample extract reanalyzed.
- 18.6.4** If calibration is verified and the diluted sample does not meet the limits for labeled compound recovery, the Method does not apply to the sample being analyzed and the result may not be reported or used for permitting or regulatory compliance purposes. In this case, alternate extraction and cleanup procedures in this Method or an alternate GC column must be employed to resolve the interference. If all cleanup procedures in this Method and an alternate GC column have been employed and labeled compound recovery remains outside of the normal range, extraction and/or cleanup procedures that are beyond this scope of this Method will be required to analyze the sample.

19.0 Pollution prevention

- 19.1** Pollution prevention encompasses any technique that reduces or eliminates the quantity or toxicity of waste at the point of generation. Many opportunities for pollution prevention exist in laboratory operation. EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address waste generation. When wastes cannot be reduced feasibly at the source, the Agency recommends recycling as the next best option.

- 19.2** The CBs in this Method are used in extremely small amounts and pose little threat to the environment when managed properly. Standards should be prepared in volumes consistent with laboratory use to minimize the disposal of excess volumes of expired standards.
- 19.3** For information about pollution prevention that may be applied to laboratories and research institutions, consult *Less is Better: Laboratory Chemical Management for Waste Reduction*, available from the American Chemical Society's Department of Governmental Relations and Science Policy, 1155 16th Street NW, Washington DC 20036, 202/872-4477.

20.0 Waste management

- 20.1** The laboratory is responsible for complying with all Federal, State, and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions, and to protect the air, water, and land by minimizing and controlling all releases from fume hoods and bench operations. Compliance is also required with any sewage discharge permits and regulations. An overview of requirements can be found in *Environmental Management Guide for Small Laboratories* (EPA 233-B-98-001).
- 20.2** Samples containing HCl or H₂SO₄ to pH <2 are hazardous and must be neutralized before being poured down a drain or must be handled as hazardous waste.
- 20.3** The CBs decompose above 800 °C. Low-level waste such as absorbent paper, tissues, animal remains, and plastic gloves may be burned in an appropriate incinerator. Gross quantities (milligrams) should be packaged securely and disposed of through commercial or governmental channels that are capable of handling extremely toxic wastes.
- 20.4** Liquid or soluble waste should be dissolved in methanol or ethanol and irradiated with ultraviolet light with a wavelength shorter than 290 nm for several days. Use F40 BL or equivalent lamps. Analyze liquid wastes, and dispose of the solutions when the CBs can no longer be detected.
- 20.5** For further information on waste management, consult *The Waste Management Manual for Laboratory Personnel* and *Less is Better-Laboratory Chemical Management for Waste Reduction*, available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th Street N.W., Washington, D.C. 20036.

21.0 Method performance

Method 1668A was validated and preliminary data were collected in a single laboratory (Reference 21). The original version of Method 1668 was validated in two single-laboratory studies. Figure 8 is a chromatogram showing method performance at each level of chlorination.

Cl No. ¹	Congener No. ^{2,3}	RT Ref ⁴	RT ⁵	RRT ⁶	RRT limits ⁷	Window (sec) ⁸	Quantitation reference ⁹	Detection limits and minimum levels - Matrix and concentration ¹⁰				
								Water (pg/L)		Other (ng/kg)		Extract (pg/μL)
								EMDL	EML	EMDL	EML	EML
8	194L	138L	57:18	1.2824	1.2777-1.2870	25	138L					

1. Number of chlorines on congener.
2. Suffix "L" indicates labeled compound.
3. Multiple congeners in a box indicates a group of congeners that co-elute or may not be adequately resolved on a 30-m SPB-octyl column. Congeners included in the group are listed as the last entry in the box.
4. Retention time (RT) reference used to locate target congener.
5. Retention time of target congener.
6. Relative retention time (RRT) between the RT for the congener and RT for the reference.
7. RRT limits based on RT window.
8. RT window width necessary to attempt to unambiguously identify the congener in the presence of other congeners.
9. Labeled congeners that form the quantitation reference. Areas from the exact m/z's of the congeners listed in the quantitation reference are summed, and divided by the number of congeners in the quantitation reference. For example, for congener 10, the areas at the exact m/z's for 4L and 15L are summed and the sum is divided by 2 (because there are 2 congeners in the quantitation reference).
10. EMDLs and EMLs with common laboratory interferences present. Without interferences, EMDLs and EMLs will be, respectively, 5 and 10 pg/L for aqueous samples, 0.5 and 1.0 ng/kg for soil, tissue, and mixed-phase samples, and EMLs for extracts will be 0.5 pg/uL.
11. If congeners 170L and 180L are included in the calibration and spiking solutions, these congeners should be used as RT and quantitation references.

10	(m+4)(m+6)]	1.16	0.99	1.33

Table 9. Suggested Sample Quantities to be Extracted for Various Matrices¹

Sample matrix ²	Example	Percent solids	Phase	Quantity extracted
Single-phase				
Aqueous	Drinking water	<1	— ³	1000 mL
	Groundwater			
	Treated wastewater			
Solid	Dry soil	>20	Solid	10 g
	Compost			
	Ash			
Organic	Waste solvent	<1	Organic	10 g
	Waste oil			
	Organic polymer			
Tissue	Fish	—	Organic	10 g
	Human adipose			
Multi-phase				
Liquid/Solid				
Aqueous/Solid	Wet soil	1-30	Solid	10 g
	Untreated effluent			
	Digested municipal sludge			
	Filter cake			
	Paper pulp			
Organic/solid	Industrial sludge	1-100	Both	10 g
	Oily waste			
Liquid/Liquid				
Aqueous/organic	In-process effluent	<1	Organic	10 g
	Untreated effluent			
	Drum waste			
Aqueous/organic/solid	Untreated effluent	>1	Organic & solid	10 g
	Drum waste			

1. The quantity of sample to be extracted is adjusted to provide 10 g of solids (dry weight). One liter of aqueous samples containing one percent solids will contain 10 grams of solids. For aqueous samples containing greater than one percent solids, a lesser volume is used so that 10 grams of solids (dry weight) will be extracted.
2. The sample matrix may be amorphous for some samples. In general, when the CBs are in contact with a multi-phase system in which one of the phases is water, they will be preferentially dispersed in or adsorbed on the alternate phase because of their low solubility in water.
3. Aqueous samples are filtered after spiking with the labeled compounds. The filtrate and the materials trapped on the filter are extracted separately, and the extracts are combined for cleanup and analysis.

24.0 Glossary

These definitions and purposes are specific to this Method but have been conformed to common usage to the extent possible.

24.1 Units of weight and measure and their abbreviations

24.1.1 Symbols

°C	degrees Celsius
μL	microliter
μm	micrometer
<	less than
>	greater than
%	percent

24.1.2 Alphabetical abbreviations

cm	centimeter
g	gram
h	hour
ID	inside diameter
in.	inch
L	liter
M	Molecular ion
m	meter
mg	milligram
min	minute
mL	milliliter
mm	millimeter
m/z	mass-to-charge ratio
N	normal; gram molecular weight of solute divided by hydrogen equivalent of solute, per liter of solution
OD	outside diameter
pg	picogram
ppb	part-per-billion
ppm	part-per-million
ppq	part-per-quadrillion
ppt	part-per-trillion
psig	pounds-per-square inch gauge
v/v	volume per unit volume
w/v	weight per unit volume

24.2 Definitions and acronyms (in alphabetical order)

Analyte—A CB tested for by this Method. The analytes are listed in Table 1.

Calibration standard (CAL)—A solution prepared from a secondary standard and/or stock solutions and used to calibrate the response of the HRGC/HRMS instrument.

Calibration verification standard (VER)—The mid-point calibration standard (CS-3) that is used to verify calibration. See Table 5.

CB—chlorinated biphenyl congener. One of the 209 individual chlorinated biphenyl congeners determined using this Method. The 209 CBs are listed in Table 1.

CS-0.2, CS-1, CS-2, CS-3, CS-4, CS-5—See Calibration standards and Table 5.

DeCB—decachlorobiphenyl (PCB 209)

DiCB—dichlorobiphenyl

Estimated method detection limit (EMDL)—The lowest concentration at which a CB can be detected with common laboratory interferences present. EMDLs are listed in Table 2.

Estimated minimum level (EML)—The lowest concentration at which a CB can be measured reliably with common laboratory interferences present. EMLs are listed in Table 2.

Field blank—An aliquot of reagent water or other reference matrix that is placed in a sample container in the laboratory or the field, and treated as a sample in all respects, including exposure to sampling site conditions, storage, preservation, and all analytical procedures. The purpose of the field blank is to determine if the field or sample transporting procedures and environments have contaminated the sample.

GC—Gas chromatograph or gas chromatography

GPC—Gel permeation chromatograph or gel permeation chromatography

HpCB—heptachlorobiphenyl

HPLC—High performance liquid chromatograph or high performance liquid chromatography

HRGC—High resolution GC

HRMS—High resolution MS

HxCB—hexachlorobiphenyl

Labeled injection internal standard—All five, or any one of the five, $^{13}\text{C}_{12}$ -labeled CB congeners spiked into the concentrated extract immediately prior to injection of an aliquot of the extract into the HRGC/HRMS. The five Labeled injection internal standards in this Method are CBs with congener numbers 9, 52, 101, 138, and 194.

Internal standard—a labeled compound used as a reference for quantitation of other labeled compounds and for quantitation of native CB congeners other than the congener of which it is a labeled analog. See Internal standard quantitation.

Internal standard quantitation—A means of determining the concentration of (1) a naturally occurring (native) compound by reference to a compound other than its labeled analog and (2) a labeled compound by reference to another labeled compound.

IPR—Initial precision and recovery; four aliquots of a reference matrix spiked with the analytes of interest and labeled compounds and analyzed to establish the ability of the laboratory to generate acceptable precision and recovery. An IPR is performed prior to the first time this Method is used and any time the Method or instrumentation is modified.

Isotope dilution quantitation—A means of determining a naturally occurring (native) compound by reference to the same compound in which one or more atoms has been isotopically enriched. In this Method, all 12 carbon atoms in the biphenyl molecule are enriched with carbon-13 to produce $^{13}\text{C}_{12}$ -labeled analogs of the chlorinated biphenyls. The $^{13}\text{C}_{12}$ -labeled CBs are spiked into each sample and allow identification and correction of the concentration of the native compounds in the analytical process.

K-D—Kuderna-Danish concentrator; a device used to concentrate the analytes in a solvent

Laboratory blank—See Method blank

Laboratory control sample (LCS)—See Ongoing precision and recovery standard (OPR)

Laboratory reagent blank—See Method blank

May—This action, activity, or procedural step is neither required nor prohibited.

May not—This action, activity, or procedural step is prohibited.

Method blank—An aliquot of reagent water that is treated exactly as a sample including exposure to all glassware, equipment, solvents, reagents, internal standards, and surrogates that are used with samples. The Method blank is used to determine if analytes or interferences are present in the laboratory environment, the reagents, or the apparatus.

Minimum level of quantitation (ML)—The level at which the entire analytical system must give a recognizable signal and acceptable calibration point for the analyte. It is equivalent to the concentration of the lowest calibration standard, assuming that all Method-specified sample weights, volumes, and cleanup procedures have been employed.

MoCB—monochlorobiphenyl

MS—Mass spectrometer or mass spectrometry

Must—This action, activity, or procedural step is required.

NoCB—nonachlorobiphenyl

OcCB—octachlorobiphenyl

OPR—Ongoing precision and recovery standard (OPR); a method blank spiked with known quantities of analytes. The OPR is analyzed exactly like a sample. Its purpose is to assure that the results produced by the laboratory remain within the limits specified in this Method for precision and recovery.

Perfluorokerosene (PFK)—A mixture of compounds used to calibrate the exact m/z scale in the HRMS.

Preparation blank—See Method blank

Quality control check sample (QCS)—A sample containing all or a subset of the analytes at known concentrations. The QCS is obtained from a source external to the laboratory or is prepared from a source of standards different from the source of calibration standards. It is used to check laboratory performance with test materials prepared external to the normal preparation process.

PeCB—pentachlorobiphenyl

PCB—polychlorinated biphenyl

Reagent water—water demonstrated to be free from the analytes of interest and potentially interfering substances at the method detection limit for the analyte.

Relative standard deviation (RSD)—The standard deviation times 100 divided by the mean. Also termed "coefficient of variation."

RF—Response factor. See Section 10.5

RR—Relative response. See Section 10.4

RSD—See Relative standard deviation

SDS—Soxhlet/Dean-Stark extractor; an extraction device applied to the extraction of solid and semi-solid materials (Reference 11 and Figure 5).

Signal-to-noise ratio (S/N)—The height of the signal as measured from the mean (average) of the noise to the peak maximum divided by the width of the noise.

Should—This action, activity, or procedural step is suggested but not required.

SICP—Selected ion current profile; the line described by the signal at an exact m/z.

SPE—Solid-phase extraction; an extraction technique in which an analyte is extracted from an aqueous sample by passage over or through a material capable of reversibly adsorbing the analyte. Also termed liquid-solid extraction.

Stock solution—A solution containing an analyte that is prepared using a reference material traceable to EPA, the National Institute of Science and Technology (NIST), or a source that will attest to the purity and authenticity of the reference material.

TeCB—tetrachlorobiphenyl

TEF—Toxicity equivalency factor; an estimate of the toxicity of a specific congener relative to 2,3,7,8-tetrachlorodibenzo-*p*-dioxin.

TEQ—the toxicity equivalent concentration in an environmental sample. It is the sum of the concentrations of each individual toxic PCB and each individual 2,3,7,8-substituted, tetra-through octachlorinated, dibenzo-*p*-dioxin and dibenzofuran multiplied by their respective TEFs (Reference 1).

TEQ_{PCB}—the portion of the TEQ attributable to the toxic PCBs.

TrCB—trichlorobiphenyl

Unique GC resolution or uniquely resolved—Two adjacent chromatographic peaks in which the height of the valley is less than 40 percent of the height of the shorter peak (See section 6.9.1.1.2 and Figures 6 and 7 for unique resolution specific to the SPB-octyl column).

VER—See Calibration verification.

Appendix A—Preliminary information for determination of 209 CBs on the DB-1 Column

1.0 Column and Conditions

1.1 Column— 30 ± 5 -m long x 0.25 ± 0.02 -mm ID; 0.25 μ m film DB-1 (J&W, or equivalent).

1.2 Suggested GC operating conditions:

Injector temperature:	270 °C
Interface temperature:	290 °C
Initial temperature:	75 °C
Initial time:	2 minutes
Temperature program:	75-150 °C at 15 °C/minute 150-270 °C at 2.5 °C/minute
Final time:	7 minutes
Carrier gas velocity:	40 cm/sec at 200 °C

Note: The GC conditions may be optimized for compound separation and sensitivity. Once optimized, the same GC conditions must be used for the analysis of all standards, blanks, IPR and OPR aliquots, and samples.

2.0 Operating Information

2.1 Congener solutions—Mixes of individual congeners that will allow separation of all w09 congeners on the DB-1 column had not been developed at the date of writing of these corrections to Method 1668A.

2.2 Elution order data—The congener mixes developed for the SPB-octyl column (Table 4 of Method 1668A) were run on the DB-1 column. Although some congeners in these mixes co-elute, the mixes allow determination of retention times for many congeners on the DB-1 column. These retention times are shown in Appendix Table A-1.

2.3 Window-defining congeners—The beginning and ending congeners at each level of chlorination are the same as for the SPB-octyl column. See Table 2 in Method 1668A.

2.4 Scan descriptors—The 6-function scan descriptors are shown in Appendix Table A-2.

Table A-1. Retention time (RT) references, quantitation references, and relative retention times (RRTs) for CB congeners using a DB-1 column.

1. Abbreviations for chlorination levels

MoCB	monochlorobiphenyl	HxCB	hexachlorobiphenyl
DiCB	dichlorobiphenyl	HpCB	heptachlorobiphenyl
TrCB	trichlorobiphenyl	OcCB	octachlorobiphenyl
TeCB	tetrachlorobiphenyl	NoCB	nonachlorobiphenyl
PeCB	pentachlorobiphenyl	DeCB	decachlorobiphenyl

2. Suffix "L" indicates labeled compound.

3. For native CBs determined by isotope dilution quantitation, RRT QC limits were constructed using -2 to +4 seconds around the retention time for the labeled analog. For native CBs determined by internal standard quantitation, RRT QC limits were constructed using a ± 2 percent window around the retention time for retention times in the range of 0.8-1.2 and a ± 4 percent window around the retention time for retention times <0.8 and >1.2 . These windows may not be adequate for analyte identification (See the note in Section 16.4)

4. Labeled level of chlorination (LOC) window-defining congener

5. Labeled level of chlorination (LOC) quantitation congener

6. National Oceanic and Atmospheric Administration (NOAA) congener of interest

7. Instrument internal standard

8. Clean-up standard

9. Labeled internal standard for World Health Organization (WHO) toxic congener

10. WHO toxic congener

Method 1668A with corrections and changes through August 20, 2003

SW-846 Method 6020 / 1-P-QM-WI-9015160

METHOD 6020A

INDUCTIVELY COUPLED PLASMA-MASS SPECTROMETRY

SW-846 is not intended to be an analytical training manual. Therefore, method procedures are written based on the assumption that they will be performed by analysts who are formally trained in at least the basic principles of chemical analysis and in the use of the subject technology.

In addition, SW-846 methods, with the exception of required method use for the analysis of method-defined parameters, are intended to be guidance methods which contain general information on how to perform an analytical procedure or technique which a laboratory can use as a basic starting point for generating its own detailed Standard Operating Procedure (SOP), either for its own general use or for a specific project application. The performance data included in this method are for guidance purposes only, and are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

1.0 SCOPE AND APPLICATION

1.1 Inductively coupled plasma-mass spectrometry (ICP-MS) is applicable to the determination of sub- $\mu\text{g/L}$ concentrations of a large number of elements in water samples and in waste extracts or digests (Refs. 1 and 2). When dissolved constituents are required, samples must be filtered and acid-preserved prior to analysis. No digestion is required prior to analysis for dissolved elements in water samples. Acid digestion prior to filtration and analysis is required for groundwater, aqueous samples, industrial wastes, soils, sludges, sediments, and other solid wastes for which total (acid-soluble) elements are required.

1.2 ICP-MS has been applied to the determination of over 60 elements in various matrices. Analytes for which EPA has demonstrated the acceptability of this method in a multi-laboratory study on solid and aqueous wastes are listed below.

Element		CASRN ^a
Aluminum	(Al)	7429-90-5
Antimony	(Sb)	7440-36-0
Arsenic	(As)	7440-38-2
Barium	(Ba)	7440-39-3
Beryllium	(Be)	7440-41-7
Cadmium	(Cd)	7440-43-9
Calcium	(Ca)	7440-70-2
Chromium	(Cr)	7440-47-3
Cobalt	(Co)	7440-48-4

Zinc	(Zn)	7440-66-6

^aChemical Abstract Service Registry Number

Acceptability of this method for an element was based upon the multi-laboratory performance compared with that of either furnace atomic absorption spectrophotometry or inductively coupled plasma-atomic emission spectrometry. It should be noted that one multi-laboratory study was conducted in 1988 and advances in ICP-MS instrumentation and software have been made since that time and additional studies have been added with validation and improvements in performance of the method. Performance, in general, exceeds the multi-laboratory performance data for the listed elements. It is expected that current performance will exceed the multi-laboratory performance data for the listed elements (and others) that are provided in Sec. 13.0. The lower limit of quantitation and linear ranges will vary with the matrices, instrumentation, and operating conditions. In relatively simple matrices, quantitation limits will generally be below 0.1 µg/L. Less sensitive elements (like Se and As) and desensitized major elements may be 1.0 µg/L or higher.

1.3 If this method is used to determine any analyte not listed in Sec. 1.2, it is the responsibility of the analyst to demonstrate the accuracy and precision of the method in the waste to be analyzed. The analyst is always required to monitor potential sources of interferences and take appropriate action to ensure data of known quality (see Sec. 9.0). Other elements and matrices may be analyzed by this method if performance is demonstrated for the analyte of interest, in the matrices of interest, at the concentration levels of interest in the same manner as the listed elements and matrices (see Sec. 9.0).

1.4 An appropriate internal standard is required for each analyte determined by ICP-MS. Recommended internal standards are ⁶Li, ⁴⁵Sc, ⁸⁹Y, ¹⁰³Rh, ¹¹⁵In, ¹⁵⁹Tb, ¹⁶⁵Ho, ⁷⁴Ge, and ²⁰⁹Bi. The lithium internal standard should have an enriched abundance of ⁶Li, so that interference from lithium native to the sample is minimized. Other elements may need to be used as internal standards when samples contain significant native amounts of the recommended internal standards.

1.5 Prior to employing this method, analysts are advised to consult the each preparative method that may be employed in the overall analysis (e.g., a 3000 series method) for additional information on quality control procedures, development of QC acceptance criteria, calculations, and general guidance. Analysts also should consult the disclaimer statement at the front of the manual and the information in Chapter Two for guidance on the intended flexibility in the choice of methods, apparatus, materials, reagents, and supplies, and on the responsibilities of the analyst for demonstrating that the techniques employed are appropriate for the analytes of interest, in the matrix of interest, and at the levels of concern.

In addition, analysts and data users are advised that, except where explicitly specified in a regulation, the use of SW-846 methods is *not* mandatory in response to Federal testing requirements. The information contained in this method is provided by EPA as guidance to be used by the analyst and the regulated community in making judgments necessary to generate results that meet the data quality objectives for the intended application.

1.6 Use of this method is restricted to use by, or under supervision of, properly experienced and trained personnel, including spectroscopists who are knowledgeable in the recognition and in the correction of spectral, chemical, and physical interferences in ICP-MS. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 Prior to analysis, samples should be solubilized or digested using the appropriate sample preparation methods (see Chapter Three). When analyzing groundwater or other aqueous samples for dissolved constituents, acid digestion is not necessary if the samples are filtered and acid preserved prior to analysis (refer to Sec. 1.1).

2.2 This method describes the multi-elemental determination of analytes by ICP-MS in environmental samples. The method measures ions produced by a radio-frequency inductively coupled plasma. Analyte species originating in a liquid are nebulized and the resulting aerosol is transported by argon gas into the plasma torch. The ions produced by high temperatures are entrained in the plasma gas and extracted through a differentially pumped vacuum interface and separated on the basis of their mass-to-charge ratio by a mass spectrometer. The ions transmitted through the mass spectrometer are quantified by a channel electron multiplier or Faraday detector and the ion information is processed by the instrument's data handling system. Interferences must be assessed and valid corrections applied or the data qualified to indicate problems. Interference correction must include compensation for background ions contributed by the plasma gas, reagents, and constituents of the sample matrix.

3.0 DEFINITIONS

Refer to Chapter One, Chapter Three, and the manufacturer's instructions for definitions that may be applicable to this procedure.

4.0 INTERFERENCES

4.1 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks. Specific selection of reagents and purification of solvents by distillation in all-glass systems may be necessary. Refer to each method to be used for specific guidance on quality control procedures and to Chapter Three for general guidance on the cleaning of glassware. Also refer to the preparative methods to be used for discussions on interferences.

4.2 Isobaric elemental interferences in ICP-MS are caused by isotopes of different elements forming atomic ions with the same nominal mass-to-charge ratio (m/z). A data system must be used to correct for these interferences. This involves determining the signal for another isotope of the interfering element and subtracting the appropriate signal from the analyte isotope signal. Since commercial ICP-MS instruments nominally provide unit resolution at 10% of the peak height, very high ion currents at adjacent masses can also contribute to ion signals at the mass of interest. Although this type of interference is uncommon, it is not easily corrected, and samples exhibiting a significant problem of this type could require resolution improvement, matrix separation, or analysis using another verified and documented isotope, or use of another method.

4.3 Isobaric molecular and doubly-charged ion interferences in ICP-MS are caused by ions consisting of more than one atom or charge, respectively. Most isobaric interferences that could affect ICP-MS determinations have been identified in the literature (Refs. 3 and 4). Examples include $^{75}\text{ArCl}^+$ ion on the ^{75}As signal and MoO^+ ions on the cadmium isotopes. While the approach used to correct for molecular isobaric interferences is demonstrated below using the natural isotope abundances from the literature (Ref. 5), the most precise coefficients for an instrument can be determined from the ratio of the net isotope signals observed for a standard solution at a concentration providing suitable (<1%) counting statistics. Because the ^{35}Cl natural abundance of 75.77% is 3.13 times the ^{37}Cl abundance of 24.23%, the chloride correction for arsenic can be calculated (approximately) as follows (where the $^{38}\text{Ar}^{37}\text{Cl}^+$ contribution at m/z 75 is a negligible 0.06% of the $^{40}\text{Ar}^{35}\text{Cl}^+$ signal):

Corrected arsenic signal (using natural isotopes abundances for coefficient approximations) =
(m/z 75 signal) - (3.13) (m/z 77 signal) + (2.73) (m/z 82 signal),

where the final term adjusts for any selenium contribution at 77 m/z.

NOTE: Arsenic values can be biased high by this type of equation when the net signal at m/z 82 is caused by ions other than $^{82}\text{Se}^+$, (e.g., $^{81}\text{BrH}^+$ from bromine wastes [Ref. 6]).

Similarly:

Corrected cadmium signal (using natural isotopes abundances for coefficient approximations) =
(m/z 114 signal) - (0.027)(m/z 118 signal) - (1.63)(m/z 108 signal),

where last 2 terms adjust for any $^{114}\text{Sn}^+$ or $^{114}\text{MoO}^+$ contributions at m/z 114.

NOTE: Cadmium values will be biased low by this type of equation when $^{92}\text{ZrO}^+$ ions contribute at m/z 108, but use of m/z 111 for Cd is even subject to direct ($^{94}\text{ZrOH}^+$) and indirect ($^{90}\text{ZrO}^+$) additive interferences when Zr is present.

NOTE: As for the arsenic equation above, the coefficients could be improved. The most appropriate coefficients for a particular instrument can be determined from the ratio of the net isotope signals observed for a standard solution at a concentration providing suitable (<1%) counting precision.

The accuracy of these types of equations is based upon the constancy of the observed isotopic ratios for the interfering species. Corrections that presume a constant fraction of a molecular ion relative to the "parent" ion have not been found (Ref. 7) to be reliable, e.g., oxide levels can vary with operating conditions. If a correction for an oxide ion is based upon the ratio of parent-to-oxide ion intensities, the correction must be adjusted for the degree of oxide formation by the use of an appropriate oxide internal standard previously demonstrated to form a similar level of oxide as the interferent. For example, this type of correction has been reported (Ref. 7) for oxide-ion corrections using ThO^+/Th^+ for the determination of rare earth elements. The use of aerosol desolvation and/or mixed gas plasmas have been shown to greatly reduce molecular interferences (Ref. 8). These techniques can be used provided that the lower limits of quantitation, accuracy, and precision requirements for analysis of the samples can be met.

4.4 Additionally, solid phase chelation may be used to eliminate isobaric interferences from both element and molecular sources. An on-line method has been demonstrated for environmental waters such as sea water, drinking water and acid decomposed samples. Acid decomposed samples refer to samples decomposed by methods similar to Methods 3052, 3051, 3050 or 3015. Samples with percent levels of iron and aluminum should be avoided. The

method also provides a method for preconcentration to enhance quantitation limits simultaneously with elimination of isobaric interferences. The method relies on chelating resins such as imminodiacetate or other appropriate resins and selectively concentrates the elements of interest while eliminating interfering elements from the sample matrix. By eliminating the elements that are direct isobaric interferences or those that form isobaric interfering molecular masses, the mass region is simplified and these interferences can not occur. The method has been proven effective for the certification of standard reference materials and validated using SRMs (Refs. 13 through 15). The method has the potential to be used on-line or off-line as an effective sample preparation method specifically designed to address interference problems.

4.5 Physical interferences are associated with the sample nebulization and transport processes as well as with ion-transmission efficiencies. Nebulization and transport processes can be affected if a matrix component causes a change in surface tension or viscosity. Changes in matrix composition can cause significant signal suppression or enhancement (Ref. 9). Dissolved solids can deposit on the nebulizer tip of a pneumatic nebulizer and on the interface skimmers (reducing the orifice size and the instrument performance). Total solid levels below 0.2% (2,000 mg/L) are recommended (Ref. 10) to minimize solid deposition. An internal standard can be used to correct for physical interferences, if it is carefully matched to the analyte so that the two elements are similarly affected by matrix changes (Ref. 11). When intolerable physical interferences are present in a sample, a significant suppression of the internal standard signals (to less than 30% of the signals in the calibrations standard) will be observed. Dilution of the sample fivefold (1+4) will usually eliminate the problem (see Sec. 9.5).

4.6 Memory interferences or carry-over can occur when there are large concentration differences between samples or standards which are analyzed sequentially. Sample deposition on the sampler and skimmer cones, spray chamber design, and the type of nebulizer affect the extent of observed memory interferences. The rinse period between samples must be long enough to eliminate significant memory interference.

5.0 SAFETY

5.1 This method does not address all safety issues associated with its use. The laboratory is responsible for maintaining a safe work environment and a current awareness file of OSHA regulations regarding the safe handling of the chemicals specified in this method. A reference file of material safety data sheets (MSDSs) should be available to all personnel involved in these analyses.

5.2 Concentrated nitric and hydrochloric acids are moderately toxic and extremely irritating to skin and mucus membranes. Use these reagents in a hood and if eye or skin contact occurs, flush with large volumes of water. Always wear safety glasses or a shield for eye protection when working with these reagents. Hydrofluoric acid is a very toxic acid and penetrates the skin and tissues deeply if not treated immediately. Injury occurs in two stages; first, by hydration that induces tissue necrosis and then by penetration of fluoride ions deep into the tissue and by reaction with calcium. Boric acid and other complexing reagents and appropriate treatment agents should be administered immediately. Consult appropriate safety literature and have the appropriate treatment materials readily available prior to working with this acid. See Method 3052 for specific suggestions for handling hydrofluoric acid from a safety and an instrument standpoint.

5.3 Many metal salts are extremely toxic if inhaled or swallowed. Extreme care must be taken to ensure that samples and standards are handled properly and that all exhaust gases are properly vented. Wash hands thoroughly after handling.

5.4 The acidification of samples containing reactive materials may result in the release of toxic gases, such as cyanides or sulfides. For this reason, the acidification and digestion of samples should be performed in an approved fume hood.

6.0 EQUIPMENT AND SUPPLIES

6.1 Inductively coupled plasma-mass spectrometer -- A system capable of providing resolution, better than or equal to 1.0 amu at 10% peak height is required. The system must have a mass range from at least 6 to 240 amu and a data system that allows corrections for isobaric interferences and the application of the internal standard technique. Use of a mass-flow controller for the nebulizer argon and a peristaltic pump for the sample solution is recommended.

6.2 Argon gas supply -- High-purity grade (99.99%).

7.0 REAGENTS AND STANDARDS

7.1 Reagent- or trace metals-grade chemicals must be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

7.2 Acids used in the preparation of standards and for sample processing must be of high purity. Redistilled acids are recommended because of the high sensitivity of ICP-MS. Nitric acid at less than 2% (v/v) is required for ICP-MS to minimize damage to the interface and to minimize isobaric molecular-ion interferences with the analytes. Many more molecular-ion interferences are observed when hydrochloric and sulfuric acids are used (Refs. 3 and 4). Concentrations of antimony and silver between 50-500 µg/L require 1% (v/v) HCl for stability; for concentrations above 500 µg/L Ag, additional HCl will be needed. Consequently, accuracy of analytes requiring significant chloride molecular ion corrections (such as As and V) will degrade.

7.3 Reagent water -- All references to water in the method refer to reagent water, unless otherwise specified. Reagent water must be free of interferences.

7.4 Standard stock solutions for each analyte may be purchased or prepared from ultra-high purity grade chemicals or metals (99.99 or greater purity). See Method 6010 for instructions on preparing standard solutions from solids.

7.4.1 Bismuth internal standard stock solution (1 mL = 100 µg of Bi) -- Dissolve 0.1115 g of Bi₂O₃ in a minimum amount of dilute HNO₃. Add 10 mL of conc. HNO₃ and dilute to 1,000 mL with reagent water.

7.4.2 Germanium internal standard stock solution (1 mL = 100 µg of Ge) -- Dissolve 0.2954 g of GeCl₄ in a minimum amount of dilute HNO₃. Add 10 mL of conc. HNO₃ and dilute to 1,000 mL with reagent water.

7.4.3 Holmium internal standard stock solution (1 mL = 100 µg of Ho) -- Dissolve 0.1757 g of Ho₂(CO₃)₂·5H₂O in 10 mL of reagent water and 10 mL of HNO₃. After dissolution is complete, warm the solution to degas. Add 10 mL conc. of HNO₃ and dilute to 1,000 mL with reagent water.

7.4.4 Indium internal standard stock solution (1 mL = 100 µg of In) -- Dissolve 0.1000 g of indium metal in 10 mL of conc. HNO₃. Dilute to 1,000 mL with reagent water.

7.4.5 Lithium internal standard stock solution (1 mL = 100 µg of ⁶Li) -- Dissolve 0.6312 g of 95-atom-% ⁶Li, Li₂CO₃ in 10 mL of reagent water and 10 mL of HNO₃. After dissolution is complete, warm the solution to degas. Add 10 mL conc. of HNO₃ and dilute to 1,000 mL with reagent water.

7.4.6 Rhodium internal standard stock solution (1 mL = 100 µg of Rh) -- Dissolve 0.3593 g of ammonium hexachlororhodate (III) (NH₄)₃RhCl₆ in 10 mL reagent water. Add 100 mL of conc. HCl and dilute to 1,000 mL with reagent water.

7.4.7 Scandium internal standard stock solution (1 mL = 100 µg of Sc) -- Dissolve 0.15343 g of Sc₂O₃ in 10 mL (1+1) of hot HNO₃. Add 5 mL of conc. HNO₃ and dilute to 1,000 mL with reagent water.

7.4.8 Terbium internal standard stock solution (1 mL = 100 µg of Tb) -- Dissolve 0.1828 g of Tb₂(CO₃)₃·5H₂O in 10 mL (1+1) of HNO₃. After dissolution is complete, warm the solution to degas. Add 5 mL of conc. HNO₃ and dilute to 1,000 mL with reagent water.

7.4.9 Yttrium internal standard stock solution (1 mL = 100 µg of Y) -- Dissolve 0.2316 g of Y₂(CO₃)₃·3H₂O in 10 mL (1+1) of HNO₃. Add 5 mL conc. of HNO₃ and dilute to 1,000 mL with reagent water.

7.4.10 Titanium interference stock solution (1 mL = 100 µg of Ti) -- Dissolve 0.4133 g of (NH₄)₂TiF₆ in reagent water. Add 2 drops of conc. HF and dilute to 1,000 mL with reagent water.

7.4.11 Molybdenum interference stock solution (1 mL = 100 µg of Mo) -- Dissolve 0.2043 g of (NH₄)₂MoO₄ in reagent water. Dilute to 1,000 mL with reagent water.

7.4.12 Gold preservative stock solution for mercury (1 mL = 100 µg) -- Recommend purchasing as high purity prepared solution of AuCl₃ in dilute hydrochloric acid matrix.

7.5 Mixed calibration standard solutions are prepared by diluting the stock-standard solutions to levels in the linear range for the instrument in a solvent consisting of 1% (v/v) HNO₃ in reagent water. The calibration standard solutions must contain a suitable concentration of an appropriate internal standard for each analyte. Internal standards may be added on-line at the time of analysis using a second channel of the peristaltic pump and an appropriate mixing manifold. Generally, an internal standard should be no more than 50 amu removed from the analyte. Recommended internal standards include ⁶Li, ⁴⁵Sc, ⁸⁹Y, ¹⁰³Rh, ¹¹⁵In, ¹⁵⁹Tb, ¹⁶⁹Ho, ⁷⁴Ge and ²⁰⁹Bi. Prior to preparing the mixed standards, each stock solution must be analyzed separately to determine possible spectral interferences or the presence of impurities. Care must be taken when preparing the mixed standards to ensure that the elements are compatible and stable together. Transfer the mixed standard solutions to freshly acid-cleaned FEP fluorocarbon or previously unused polyethylene or polypropylene bottles for storage. For all intermediate and working standards, especially low level standards (i.e., <1 ppm), stability must be demonstrated prior to use. Fresh mixed standards must be prepared as needed with the realization that concentrations can change on aging. (Refer to Sec. 10.3.1 for guidance on determining the viability of standards.)

7.6 Blanks -- Three types of blanks are required for the analysis. The calibration blank is used in establishing the calibration curve. The method blank is used to monitor for

possible contamination resulting from either the reagents (acids) or the equipment used during sample processing including filtration. The rinse blank is used to flush the system between all samples and standards.

7.6.1 The calibration blank consists of the same concentration(s) of the same acid(s) used to prepare the final dilution of the calibrating solutions of the analytes [often 1% HNO₃ (v/v) in reagent water] along with the selected concentrations of internal standards such that there is an appropriate internal standard element for each of the analytes. Use of HCl for antimony and silver is cited in Sec. 7.2.

7.6.2 The method blank must contain all of the reagents in the same volumes as used in the processing of the samples. The method blank must be carried through the complete procedure and contain the same acid concentration in the final solution as the sample solution used for analysis (refer to Sec. 9.9).

7.6.3 The rinse blank consists of 1 to 2% of HNO₃ (v/v) in reagent water. Prepare a sufficient quantity to flush the system between standards and samples. If mercury is to be analyzed, the rinse blank should also contain 2 µg/mL (ppm) of AuCl₃ solution.

7.7 The interference check solution (ICS) is prepared to contain known concentrations of interfering elements that will demonstrate the magnitude of interferences and provide an adequate test of any corrections. Chloride in the ICS provides a means to evaluate software corrections for chloride-related interferences such as ³⁵Cl¹⁶O⁺ on ⁵¹V⁺ and ⁴⁰Ar³⁵Cl⁺ on ⁷⁵As⁺. Iron is used to demonstrate adequate resolution of the spectrometer for the determination of manganese. Molybdenum serves to indicate oxide effects on cadmium isotopes. The other components are present to evaluate the ability of the measurement system to correct for various molecular-ion isobaric interferences. The ICS is used to verify that the interference levels are corrected by the data system within quality control limits.

NOTE: The final ICS solution concentrations in Table 1 are intended to evaluate corrections for known interferences on only the analytes in Sec. 1.2. If this method is used to determine an element not listed in Sec. 1.2, the analyst should modify the ICS solutions, or prepare an alternative ICS solution, to allow adequate verification of correction of interferences on the unlisted element (see Sec. 9.7).

7.7.1 These solutions must be prepared from ultra-pure reagents. They can be obtained commercially or prepared by the following procedure.

7.7.1.1 Mixed ICS solution I may be prepared by adding 13.903 g of Al(NO₃)₃·9H₂O, 2.498 g of CaCO₃ (dried at 180 °C for 1 hr before weighing), 1.000 g of Fe, 1.658 g of MgO, 2.305 g of Na₂CO₃, and 1.767 g of K₂CO₃ to 25 mL of reagent water. Slowly add 40 mL of (1+1) HNO₃. After dissolution is complete, warm the solution to degas. Cool and dilute to 1,000 mL with reagent water.

7.7.1.2 Mixed ICS solution II may be prepared by slowly adding 7.444 g of 85 % H₃PO₄, 6.373 g of 96% H₂SO₄, 40.024 g of 37% HCl, and 10.664 g of citric acid C₆O₇H₈ to 100 mL of reagent water. Dilute to 1,000 mL with reagent water.

7.7.1.3 Mixed ICS solution III may be prepared by adding 1.00 mL each of 100-µg/mL arsenic, cadmium, selenium, chromium, cobalt, copper, manganese, nickel, silver, vanadium, and zinc stock solutions to about 50 mL of

reagent water. Add 2.0 mL of concentrated HNO₃, and dilute to 100.0 mL with reagent water.

7.7.1.4 Working ICS solutions

7.7.1.4.1 ICS-A may be prepared by adding 10.0 mL of mixed ICS solution I (Sec. 7.7.1.1), 2.0 mL each of 100-µg/mL titanium stock solution (Sec. 7.4.9) and molybdenum stock solution (Sec. 7.4.10), and 5.0 mL of mixed ICS solution II (Sec. 7.7.1.2). Dilute to 100 mL with reagent water. ICS solution A must be prepared fresh weekly.

7.7.1.4.2 ICS-AB may be prepared by adding 10.0 mL of mixed ICS solution I (Sec. 7.7.1.1), 2.0 mL each of 100-µg/mL titanium stock solution (Sec. 7.4.9) and molybdenum stock solution (Sec. 7.4.10), 5.0 mL of mixed ICS solution II (Sec. 7.7.1.2), and 2.0 mL of mixed ICS solution III (Sec. 7.7.1.3). Dilute to 100 mL with reagent water. Although the ICS solution AB must be prepared fresh weekly, the analyst should be aware that the solution may precipitate silver more quickly.

7.8 The initial calibration verification (ICV) standard is prepared by the analyst (or a purchased second source reference material) by combining compatible elements from a standard source different from that of the calibration standard, and at concentration near the midpoint of the calibration curve (see Sec. 10.4.3 for use). This standard may also be purchased.

7.9 The continuing calibration verification (CCV) standard should be prepared in the same acid matrix using the same standards used for calibration, at a concentration near the mid-point of the calibration curve (see Sec. 10.4.4 for use).

7.10 Mass spectrometer tuning solution. A solution containing elements representing all of the mass regions of interest (for example, 10 µg/L of Li, Co, In, and Tl) must be prepared to verify that the resolution and mass calibration of the instrument are within the required specifications (see Sec. 10.2). This solution is also used to verify that the instrument has reached thermal stability (see Sec. 11.4).

8.0 SAMPLE COLLECTION, PRESERVATION, AND STORAGE

8.1 See the introductory material in Chapter Three, "Inorganic Analytes."

8.2 Only polyethylene or fluorocarbon (TFE or PFA) containers are recommended for use in this method.

9.0 QUALITY CONTROL

9.1 Refer to Chapter One for additional guidance on quality assurance (QA) and quality control (QC) protocols. When inconsistencies exist between QC guidelines, method-specific QC criteria take precedence over both technique-specific criteria and those criteria given in Chapter One, and technique-specific QC criteria take precedence over the criteria in Chapter One. Any effort involving the collection of analytical data should include development of a structured and systematic planning document, such as a Quality Assurance Project Plan (QAPP) or a Sampling and Analysis Plan (SAP), which translates project objectives and specifications into directions for those that will implement the project and assess the results.

Each laboratory should maintain a formal quality assurance program. The laboratory should also maintain records to document the quality of the data generated. All data sheets and quality control data should be maintained for reference or inspection.

9.2 Refer to a 3000 series method (Method 3005, 3010, 3015, 3031, 3040, 3050, 3051, or 3052) for appropriate QC procedures to ensure the proper operation of the various sample preparation techniques.

9.3 Instrument detection limits (IDLs) are a useful tool to evaluate the instrument noise level and response changes over time for each analyte from a series of reagent blank analyses to obtain a calculated concentration. They are not to be confused with the lower limits of quantitation, nor should they be used in establishing this limit. It may be helpful to compare the calculated IDLs to the established lower limit of quantitation, however, it should be understood that the lower limit of quantitation needs to be verified according to the guidance in Sec. 10.2.3.

IDLs in $\mu\text{g/L}$ can be estimated by calculating the average of the standard deviations of three runs on three non-consecutive days from the analysis of a reagent blank solution with seven consecutive measurements per day. Each measurement should be performed as though it were a separate analytical sample (i.e., each measurement must be followed by a rinse and/or any other procedure normally performed between the analysis of separate samples). IDLs should be determined at least every three months or at a project-specific designated frequency and kept with the instrument log book. Refer to Chapter One for additional guidance.

9.4 Initial demonstration of proficiency

Each laboratory must demonstrate initial proficiency with each sample preparation (a 3000 series method) and determinative method combination it utilizes by generating data of acceptable accuracy and precision for target analytes in a clean matrix. If an autosampler is used to perform sample dilutions, before using the autosampler to dilute samples, the laboratory should satisfy itself that those dilutions are of equivalent or better accuracy than is achieved by an experienced analyst performing manual dilutions. The laboratory must also repeat the demonstration of proficiency whenever new staff members are trained or significant changes in instrumentation are made.

9.5 Dilute and reanalyze samples that exceed the linear dynamic range or use an alternate, less sensitive calibration for which quality control data are already established.

9.6 The intensities of all internal standards must be monitored for every analysis. If the intensity of any internal standard in a sample falls below 70% of the intensity of that internal standard in the initial calibration standard, a significant matrix effect must be suspected. As an example, if the initial calibration internal standard response is 100,000 cps, anything below 70,000 cps in the sample would be unacceptable. Under these conditions, the established lower limit of quantitation has degraded and the correction ability of the internal standardization technique becomes questionable. The following procedure is followed -- First, make sure the instrument has not drifted by observing the internal standard intensities in the nearest clean matrix (calibration blank, Sec. 7.6.1). If the low internal standard intensities are also seen in the nearest calibration blank, terminate the analysis, correct the problem, recalibrate, verify the new calibration, and reanalyze the affected samples. If drift has not occurred, matrix effects need to be removed by dilution of the affected sample. The sample must be diluted fivefold (1+4) and reanalyzed with the addition of appropriate amounts of internal standards. If the first dilution does not eliminate the problem, this procedure must be repeated until the internal-standard intensities rise to the minimum 70% limit. Reported results must be corrected for all dilutions.

9.7 To obtain analyte data of known quality, it is necessary to measure more than the analytes of interest in order to apply corrections or to determine whether interference corrections are necessary. For example, tungsten oxide moleculars can be very difficult to distinguish from mercury isotopes. If the concentrations of interference sources (such as C, Cl, Mo, Zr, W) are such that, at the correction factor, the analyte is less than the limit of quantification and the concentration of interferents are insignificant, then the data may go uncorrected. Note that monitoring the interference sources does not necessarily require monitoring the interferant itself, but that a molecular species may be monitored to indicate the presence of the interferent. When correction equations are used, all QC criteria must also be met. Extensive QC for interference corrections are required at all times. The monitored masses must include those elements whose hydrogen, oxygen, hydroxyl, chlorine, nitrogen, carbon and sulfur molecular ions could impact the analytes of interest. Unsuspected interferences may be detected by adding pure major matrix components to a sample to observe any impact on the analyte signals. When an interference source is present, the sample elements impacted must be flagged to indicate (a) the percentage interference correction applied to the data or (b) an uncorrected interference by virtue of the elemental equation used for quantitation. The isotope proportions for an element or molecular-ion cluster provide information useful for quality assurance.

NOTE: Only isobaric elemental, molecular, and doubly charged interference corrections which use the observed isotopic-response ratios or parent-to-oxide ratios (provided an oxide internal standard is used as described in Sec. 4.2) for each instrument system are acceptable corrections for use in Method 6020.

9.8 For each batch of samples processed, at least one method blank must be carried throughout the entire sample preparation and analytical process, as described in Chapter One. A method blank is prepared by using a volume or weight of reagent water at the volume or weight specified in the preparation method, and then carried through the appropriate steps of the analytical process. These steps may include, but are not limited to, prefiltering, digestion, dilution, filtering, and analysis. If the method blank does not contain target analytes at a level that interferes with the project-specific DQOs, then the method blank would be considered acceptable.

In the absence of project-specific DQOs, if the blank is less than 10% of the lower limit of quantitation check sample concentration, less than 10% of the regulatory limit, or less than 10% of the lowest sample concentration for each analyte in a given preparation batch, whichever is greater, then the method blank is considered acceptable. If the method blank cannot be considered acceptable, the method blank should be re-run once, and if still unacceptable, then all samples after the last acceptable method blank should be reprepared and reanalyzed along with the other appropriate batch QC samples. These blanks will be useful in determining if samples are being contaminated. If the method blank exceeds the criteria, but the samples are all either below the reporting level or below the applicable action level or other DQOs, then the sample data may be used despite the contamination of the method blank.

9.9 Laboratory control sample (LCS)

For each batch of samples processed, at least one LCS must be carried throughout the entire sample preparation and analytical process. The laboratory control samples should be spiked with each analyte of interest at the project-specific action level or, when lacking project-specific action levels, at approximately mid-point of the linear dynamic range. Acceptance criteria should either be defined in the project-specific planning documents or set at a laboratory derived limit developed through the use of historical analyses. In the absence of project-specific or historical data generated criteria, this limit should be set at $\pm 20\%$ of the spiked value. Acceptance limits derived from historical data should be no wider than $\pm 20\%$. If the laboratory control sample is not acceptable, then the laboratory control sample should be re-run once and,

if still unacceptable, all samples after the last acceptable laboratory control sample should be reprepared and reanalyzed.

Concurrent analyses of standard reference materials (SRMs) containing known amounts of analytes in the media of interest are recommended and may be used as an LCS. For solid SRMs, 80 - 120% accuracy may not be achievable and the manufacturer's established acceptance criterion should be used for soil SRMs.

9.10 Matrix spike, unspiked duplicate, or matrix spike duplicate (MS/Dup or MS/MSD)

Documenting the effect of the matrix, for a given preparation batch consisting of similar sample characteristics, should include the analysis of at least one matrix spike and one duplicate unspiked sample or one matrix spike/matrix spike duplicate pair. The decision on whether to prepare and analyze duplicate samples or a matrix spike/matrix spike duplicate must be based on a knowledge of the samples in the sample batch or as noted in the project-specific planning documents. If samples are expected to contain target analytes, then laboratories may use one matrix spike and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes, laboratories should use a matrix spike and matrix spike duplicate pair.

For each batch of samples processed, at least one MS/Dup or MS/MSD sample set should be carried throughout the entire sample preparation and analytical process as described in Chapter One. MS/MSDs are intralaboratory split samples spiked with identical concentrations of each analyte of interest. The spiking occurs prior to sample preparation and analysis. An MS/Dup or MS/MSD is used to document the bias and precision of a method in a given sample matrix.

Refer to Chapter One for definitions of bias and precision, and for the proper data reduction protocols. MS/MSD samples should be spiked at the same level, and with the same spiking material, as the corresponding laboratory control sample that is at the project-specific action level or, when lacking project-specific action levels, at approximately mid-point of the linear dynamic range. Acceptance criteria should either be defined in the project-specific planning documents or set at a laboratory-derived limit developed through the use of historical analyses per matrix type analyzed. In the absence of project-specific or historical data generated criteria, these limits should be set at $\pm 25\%$ of the spiked value for accuracy and 20 relative percent difference (RPD) for precision. Acceptance limits derived from historical data should be no wider than $\pm 25\%$ for accuracy and 20% for precision. Refer to Chapter One for additional guidance. If the bias and precision indicators are outside the laboratory control limits, if the percent recovery is less than 75% or greater than 125%, or if the relative percent difference is greater than 20%, then the interference test discussed in Sec. 9.11 should be conducted.

9.10.1 The relative percent difference between spiked matrix duplicate or unspiked duplicate determinations is to be calculated as follows:

$$RPD = \frac{D_1 \text{ \& } D_2}{\left(\frac{D_1 + D_2}{2} \right)} \times 100$$

where:

RPD = relative percent difference.

- D₁ = first sample value.
D₂ = second sample value (spiked or unspiked duplicate).

9.10.2 The spiked sample or spiked duplicate sample recovery should be within $\pm 25\%$ of the actual value, or within the documented historical acceptance limits for each matrix.

9.11 If less than acceptable accuracy and precision data are generated, additional quality control tests (Secs. 9.11.1 and 9.11.2) are recommended prior to reporting concentration data for the elements in this method. At a minimum these tests should be performed with each batch of samples prepared/analyzed with corresponding unacceptable data quality results. These test will then serve to ensure that neither positive nor negative interferences are affecting the measurement of any of the elements or distorting the accuracy of the reported values. If matrix effects are confirmed, the laboratory should consult with the data user when feasible for possible corrective actions which may include the use of alternative or modified test procedures so that the analysis is not impacted by the same interference.

9.11.1 Post digestion spike addition

If the MS/MSD recoveries are unacceptable, the same sample from which the MS/MSD aliquots were prepared should also be spiked with a post digestion spike. Otherwise another sample from the same preparation should be used as an alternative. An analyte spike is added to a portion of a prepared sample, or its dilution, and should be recovered to within 80% to 120% of the known value. The spike addition should produce a minimum level of 10 times and a maximum of 100 times the lower limit of quantitation. If this spike fails, then the dilution test (Sec. 9.11.2) should be run on this sample. If both the MS/MSD and the post digestion spike fail, then matrix effects are confirmed.

9.11.2 Dilution test

If the analyte concentration is sufficiently high (minimally, a factor of 10 above the lower limit of quantitation after dilution), an analysis of a 1:5 dilution should agree within $\pm 10\%$ of the original determination. If not, then a chemical or physical interference effect should be suspected.

9.12 Ultra-trace analysis requires the use of clean chemistry preparation and analysis techniques. Several suggestions for minimizing analytical blank contamination are provided in Chapter Three.

10.0 CALIBRATION AND STANDARDIZATION

10.1 Set up the instrument with proper operating parameters established as detailed below. The instrument should be allowed to become thermally stable before beginning (usually requiring at least 30 min of operation prior to calibration). For operating conditions, the analyst should follow the instructions provided by the instrument manufacturer.

10.2 Conduct mass calibration and resolution checks in the mass regions of interest. The mass calibration and resolution parameters are required criteria which must be met prior to any samples being analyzed. If the mass calibration differs more than 0.1 amu from the true value, then the mass calibration must be adjusted to the correct value. The resolution must also be verified to be less than 0.9 amu full width at 10% peak height.

10.2.1 Before using this procedure to analyze samples, data should be available documenting the initial demonstration of performance. The required data should document the determination of the linear dynamic ranges; a demonstration of the desired method sensitivity and instrument detection limits; and the determination and verification of the appropriate correction equations or other routines for correcting spectral interferences. These data should be generated using the same instrument, operating conditions, and calibration routine to be used for sample analysis. These data should be kept on file and be available for review by the data user or auditor.

10.2.2 Sensitivity, instrumental detection limit, precision, linear dynamic range, and interference corrections need to be established for each individual target analyte on each particular instrument. All measurements (both target analytes and constituents which interfere with the target analytes) need to be within the instrument linear range where the correction equations are valid.

10.2.3 The lower limits of quantitation should be established for all isotope masses utilized for each type of matrix analyzed and for each preparation method used and for each instrument. These limits are considered the lowest reliable laboratory reporting concentrations and should be established from the lower limit of quantitation check sample and then confirmed using either the lowest calibration point or from a low-level calibration check standard.

10.2.3.1 Lower limit of quantitation check sample

The lower limit of quantitation check (LLQC) sample should be analyzed after establishing the lower laboratory reporting limits and on an as needed basis to demonstrate the desired detection capability. Ideally, this check sample and the low-level calibration verification standard will be prepared at the same concentrations with the only difference being the LLQC sample is carried through the entire preparation and analytical procedure. Lower limits of quantitation are verified when all analytes in the LLQC sample are detected within $\pm 30\%$ of their true value. This check should be used to both establish and confirm the lowest quantitation limit.

10.2.3.2 The lower limits of quantitation determination using reagent water represents a best case situation and does not represent possible matrix effects of real-world samples. For the application of lower limits of quantitation on a project-specific basis with established data quality objectives, low-level matrix-specific spike studies may provide data users with a more reliable indication of the actual method sensitivity and minimum detection capabilities.

10.2.4 Specific recommended isotopes for the analytes noted in Sec. 1.2 are provided in Table 2. Other isotopes may be substituted if they can provide the needed sensitivity and are corrected for spectral interference. Because of differences among various makes and models of mass spectrometers, specific instrument operating conditions cannot be provided. The instrument and operating conditions utilized for determination must be capable of providing data of acceptable quality for the specific project and data user. The analyst should follow the instructions provided by the instrument manufacturer unless other conditions provide similar or better performance for a given task.

10.3 All masses which could affect data quality should be monitored to determine potential effects from matrix components on the analyte peaks. The recommended isotopes to be monitored are listed in Table 2.

10.4 All analyses require that a calibration curve be prepared to cover the appropriate concentration range based on the intended application and prior to establishing the linear dynamic range. Usually, this means the preparation of a calibration blank and mixed calibration standard solutions (Sec. 7.5), the highest of which would not exceed the anticipated linear dynamic range of the instrument. Check the instrument standardization by analyzing appropriate QC samples as follows.

10.4.1 Individual or mixed calibration standards should be prepared from known primary stock standards every six months to one year as needed based on the concentration stability as confirmed from the ICV analyses. The analysis of the ICV, which is prepared from a source independent of the calibration standards, is necessary to verify the instrument performance once the system has been calibrated for the desired target analytes. It is recommended that the ICV solution be obtained commercially as a certified traceable reference material such that an expiration date can be assigned. Alternately, the ICV solution can be prepared from an independent source on an as needed basis depending on the ability to meet the calibration verification criteria. If the ICV analysis is outside of the acceptance criteria, at a minimum the calibration standards must be prepared fresh and the instrument recalibrated prior to beginning sample analyses. Consideration should also be given to preparing fresh ICV standards if the new calibration cannot be verified using the existing ICV standard.

NOTE: This method describes the use of both a low-level and mid-level ICV standard analysis. For purposes of verifying the initial calibration, only the mid-level ICV needs to be prepared from a source other than the calibration standards.

10.4.1.1 The calibration standards should be prepared using the same type of acid or combination of acids and at similar concentrations as will result in the samples following processing.

10.4.1.2 The response of the calibration blank should be less than the response of the typical laboratory lower limit of quantitation for each desired target analyte. Additionally, if the calibration blank response or continuing calibration blank verification is used to calculate a theoretical concentration, this value should be less than the level of acceptable blank contamination as specified in the approved quality assurance project planning documents. If this is not the case, the reason for the out-of-control condition must be found and corrected, and the sample analyses may not proceed or the previous ten samples need to be reanalyzed.

10.4.2 For the initial and daily instrument operation, calibrate the system according to the instrument manufacturer's guidelines using the mixed calibration standards as noted in Sec. 7.5. The calibration curve should be prepared daily with a minimum of a calibration blank and a single standard at the appropriate concentration to effectively outline the desired quantitation range. Flush the system with the rinse blank (Sec. 7.6.3) between each standard solution. Use the average of at least three integrations for both calibration and sample analyses. The resulting curve should then be verified with mid-level and low-level initial calibration verification standards as outlined in Sec. 10.4.3.

Alternatively, the calibration curve can be prepared daily with a minimum of a calibration blank and three non-zero standards that effectively bracket the desired sample concentration range. If low-level as compared to mid- or high-level sample concentrations are expected, the calibration standards should be prepared at the appropriate concentrations in order to demonstrate the instrument linearity within the anticipated

sample concentration range. For all multi-point calibration scenarios, the lowest non-zero standard concentration should be considered the lower limit of quantitation.

NOTE: Regardless of whether the instrument is calibrated using only a minimum number of standards or with a multi-point curve, the upper limit of the quantitation range may exceed the highest concentration calibration point and can be defined as the "linear dynamic" range, while the lower limit can be identified as the "lower limit of quantitation limit" (LLQL) and will be either the concentration of the lowest calibration standard (for multi-point curves) or the concentration of the low level ICV/CCV check standard. Results reported outside these limits would not be recommended unless they are qualified as estimated. See Sec. 10.4.4 for recommendations on how to determine the linear dynamic range, while the guidance in this section and Sec. 10.4.3 provide options for defining the lower limit of quantitation.

10.4.2.1 To be considered acceptable, the calibration curve should have a correlation coefficient greater than or equal to 0.998. When using a multi-point calibration curve approach, every effort should be made to attain an acceptable correlation coefficient based on a linear response for each desired target analyte. If the recommended linear response cannot be attained using a minimum of three non-zero calibration standards, consideration should be given to adding more standards, particularly at the lower concentrations, in order to better define the linear range and the lower limit of quantitation. Conversely, the extreme upper and lower calibration points may be removed from the multi-point curve as long as three non-zero points remain such that the linear range is narrowed and the non-linear upper and/or lower portions are removed. As with the single point calibration option, the multi-point calibration should be verified with both a mid- and low-level ICV standard analysis using the same 90 - 110% and 70 - 130% acceptance criteria, respectively.

10.4.2.2 Many instrument software packages allow multi-point calibration curves to be "forced" through zero. It is acceptable to use this feature, provided that the resulting calibration meets the acceptance criteria, and can be verified by acceptable QC results. Forcing a regression through zero should NOT be used as a rationale for reporting results below the calibration range defined by the lowest standard in the calibration curve.

10.4.3 After initial calibration, the calibration curve should be verified by use of an initial calibration verification (ICV) standard analysis. At a minimum, the ICV standard should be prepared from an independent (second source) material at or near the mid-range of the calibration curve. The acceptance criteria for this mid-range ICV standard should be $\pm 10\%$ of its true value. Additionally, a low-level initial calibration verification (LLICV) standard should be prepared, using the same source as the calibration standards, at a concentration expected to be the lower limit of quantitation. The suggested acceptance criteria for the LLICV is $\pm 30\%$ of its true value. Quantitative sample analyses should not proceed for those analytes that fail the second source standard initial calibration verification, with the exception that analyses may continue for those analytes that fail the criteria with an understanding these results should be qualified and would be considered estimated values. Once the calibration acceptance criteria is met, either the lowest calibration standard or the LLICV concentration can be used to demonstrate the lower limit of quantitation and sample results should not be quantitated below this lowest standard. In some cases depending on the stated project data quality objectives, it may be appropriate to report these results as estimated, however, they should be qualified by noting the results are below the lower limit of quantitation. Therefore, the laboratory's

quantitation limit cannot be reported lower than either the LLICV standard used for the single point calibration option or the low calibration and/or verification standard used during initial multi-point calibration. If the calibration curve cannot be verified within these specified limits for the mid-range ICV and LLICV analyses, the cause needs to be determined and the instrument recalibrated before samples are analyzed. The analysis data for the initial calibration verification analyses should be kept on file with the sample analysis data.

10.4.4 Both the single and multi-point calibration curves should be verified at the end of each analysis batch and after every 10 samples by use of a continuing calibration verification (CCV) standard and a continuing calibration blank (CCB). The CCV should be made from the same material as the initial calibration standards at or near the mid-range concentration. For the curve to be considered valid, the acceptance criteria for the CCV standard should be $\pm 10\%$ of its true value and the CCB should contain target analytes less than the established lower limit of quantitation for any desired target analyte. If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the cause determined and the instrument recalibrated. All samples following the last acceptable CCV/CCB must be reanalyzed. The analysis data for the CCV/CCB should be kept on file with the sample analysis data.

The low level continuing calibration verification (LLCCV) standard should also be analyzed at the end of each analysis batch. A more frequent LLCCV analysis, i.e., every 10 samples may be necessary if low-level sample concentrations are anticipated and the system stability at low end of the calibration is questionable. In addition, the analysis of a LLCCV on a more frequent basis will minimize the number of samples for re-analysis should the LLCCV fail if only run at the end of the analysis batch. The LLCCV standard should be made from the same source as the initial calibration standards at the established lower limit of quantitation as reported by the laboratory. The acceptance criteria for the LLCCV standard should be $\pm 30\%$ of its true value. If the calibration cannot be verified within these specified limits, the analysis of samples containing the affected analytes at similar concentrations cannot continue until the cause is determined and the LLCCV standard successfully analyzed. The instrument may need to be recalibrated or the lower limit of quantitation adjusted to a concentration that will ensure a compliant LLCCV analysis. The analysis data for the LLCCV standard should be kept on file with the sample analysis data.

10.5 Verify the magnitude of elemental and molecular-ion isobaric interferences and the adequacy of any corrections at the beginning of an analytical run or once every 12 hr, whichever is more frequent. Do this by analyzing the interference check solutions A and AB. The analyst should be aware that precipitation from solution AB may occur with some elements, specifically silver. Refer to Sec. 4.0 for a discussion on interferences and potential solutions to those interferences if additional guidance is needed.

NOTE: Analysts have noted improved performance in calibration stability if the instrument is exposed to the interference check solution after cleaning sampler and skimmer cones. Improved performance is also realized if the instrument is allowed to rinse for 5 or 10 min before the calibration blank is run.

10.6 The linear dynamic range is established when the system is first setup, or whenever significant instrument components have been replaced or repaired, and on an as needed basis only after the system has been successfully calibrated using either the single or multi-point standard calibration approach.

The upper limit of the linear dynamic range needs to be established for each wavelength utilized by determining the signal responses from a minimum of three, preferably five, different concentration standards across the range. The ranges which may be used for the analysis of samples should be judged by the analyst from the resulting data. The data, calculations and rationale for the choice of range made should be documented and kept on file. A standard at the upper limit should be prepared, analyzed and quantitated against the normal calibration curve. The calculated value should be within 10% ($\pm 10\%$) of the true value. New upper range limits should be determined whenever there is a significant change in instrument response. At a minimum, the range should be checked every six months. The analyst should be aware that if an analyte that is present above its upper range limit is used to apply a spectral correction, the correction may not be valid and those analytes where the spectral correction has been applied may be inaccurately reported.

NOTE: Some metals may exhibit non-linear response curves due to ionization and self-absorption effects. These curves may be used if the instrument allows it; however the effective range must be checked and the second order curve fit should have a correlation coefficient of 0.998 or better. Third order fits are not acceptable. These non-linear response curves should be revalidated and/or recalculated on a daily basis using the same calibration verification QC checks as a linear calibration curve. Since these curves are much more sensitive to changes in operating conditions than the linear lines, they should be checked whenever there have been moderate equipment changes. Under these calibration conditions, quantitation is not acceptable above or below the calibration standards. Additionally, a non-linear curve should be further verified by calculating the actual recovery of each calibration standard used in the curve. The acceptance criteria for the calibration standard recovery should be $\pm 10\%$ of its true value for all standards except the lowest concentration. A recovery of $\pm 30\%$ of its true value should be achieved for the lowest concentration standard.

10.7 The analyst should (1) verify that the instrument configuration and operating conditions satisfy the project-specific analytical requirements and (2) maintain quality control data that demonstrate and confirm the instrument performance for the reported analytical results.

11.0 PROCEDURE

11.1 Preliminary treatment of most matrices is necessary because of the complexity and variability of sample matrices. Groundwater and other aqueous samples designated for a dissolved metals determination which have been prefiltered and acidified will not need acid digestion. However, all associated QC samples (i.e., method blank, LCS and MS/MSD) must undergo the same filtration and acidification procedures. Samples which are not digested must be matrix-matched with the standards. Solubilization and digestion procedures are presented in Chapter Three, "Inorganic Analytes."

CAUTION: If mercury is to be analyzed, the digestion procedure must use mixed nitric and hydrochloric acids through all steps of the digestion. Mercury will be lost if the sample is digested when hydrochloric acid is not present. If it has not already been added to the sample as a preservative, Au should be added to give a final concentration of 2 mg/L (use 2.0 mL of 7.4.12 per 100 mL of sample) to preserve the mercury and to prevent it from plating out in the sample introduction system.

11.2 Initiate appropriate operating configuration of the instrument's computer according to the instrument manufacturer's instructions.

11.3 Set up the instrument with the proper operating parameters according to the instrument manufacturer's instructions.

11.4 Operating conditions -- The analyst should follow the instructions provided by the instrument manufacturer. Allow at least 30 min for the instrument to equilibrate before analyzing any samples. This must be verified by an analysis of the tuning solution (Sec. 7.10) at least four integrations with relative standard deviations of #5% for the analytes contained in the tuning solution.

CAUTION: The instrument should have features that protect itself from high ion currents. If not, precautions must be taken to protect the detector from high ion currents. A channel electron multiplier or active film multiplier suffers from fatigue after being exposed to high ion currents. This fatigue can last from several seconds to hours depending on the extent of exposure. During this time period, response factors are constantly changing, which invalidates the calibration curve, causes instability, and invalidates sample analyses.

11.5 Calibrate the instrument following the procedure outlined in Sec. 10.0.

11.6 Flush the system with the rinse blank solution (Sec. 7.6.3) until the signal levels return to the DQO or method's levels of quantitation (usually about 30 sec) before the analysis of each sample (see Sec. 10.0). Nebulize each sample until a steady-state signal is achieved (usually about 30 sec) prior to collecting data. Flow-injection systems may be used as long as they can meet the performance criteria of this method.

11.7 Regardless of whether the initial calibration is performed using a single high standard and the calibration blank or the multi-point option, the laboratory should analyze an LLCCV (Sec. 10.4.4). For all analytes and determinations, the laboratory must analyze an ICV and LLICV (Sec. 10.4.3) immediately following daily calibration. It is recommended that a CCV LLCCV, and CCB (Sec. 10.4.4) be analyzed after every ten samples and at the end of the analysis batch.

11.8 Dilute and reanalyze samples that are more concentrated than the linear range for an analyte (or species needed for a correction) or measure an alternate but less-abundant isotope. The linearity at the alternate mass must be confirmed by appropriate calibration (see Sec. 10.2 and 10.4). Alternatively apply solid phase chelation chromatography to eliminate the matrix as described in Sec. 4.4.

12.0 DATA ANALYSIS AND CALCULATIONS

12.1 The quantitative values must be reported in appropriate units, such as micrograms per liter ($\mu\text{g/L}$) for aqueous samples and milligrams per kilogram (mg/kg) for solid samples. If dilutions were performed, the appropriate corrections must be applied to the sample values. All results should be reported with up to three significant figures.

12.2 If appropriate, or required, calculate results for solids on a dry-weight basis as follows:

- (1) A separate determination of percent solids must be performed.
- (2) The concentrations determined in the digest are to be reported on the basis of the dry weight of the sample.

$$\text{Concentration (dry weight)(mg/kg)} = \frac{C \times V}{W \times S}$$

Where,

C = Digest Concentration (mg/L)

V = Final volume in liters after sample preparation

W = Weight in kg of wet sample

$$S = \frac{\% \text{ Solids}}{100}$$

Calculations must include appropriate interference corrections (see Sec. 4.2 for examples), internal-standard normalization, and the summation of signals at 206, 207, and 208 m/z for lead (to compensate for any differences in the abundances of these isotopes between samples and standards).

12.3 Results must be reported in units commensurate with their intended use and all dilutions must be taken into account when computing final results.

13.0 METHOD PERFORMANCE

13.1 Performance data and related information are provided in SW-846 methods only as examples and guidance. The data do not represent required performance criteria for users of the methods. Instead, performance criteria should be developed on a project-specific basis, and the laboratory should establish in-house QC performance criteria for the application of this method. These performance data are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

13.2 In an EPA multi-laboratory study (Ref. 12), twelve laboratories applied the ICP-MS technique to both aqueous and solid samples. Table 3 summarizes the method performance data for aqueous samples. Performance data for solid samples are provided in Table 4. These data are provided for guidance purposes only.

13.3 Table 5 summarizes the method performance data for aqueous and sea water samples with interfering elements removed and samples preconcentrated prior to analysis. Table 6 summarizes the performance data for a simulated drinking water standard. These data are provided for guidance purposes only.

14.0 POLLUTION PREVENTION

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity and/or toxicity of waste at the point of generation. Numerous opportunities for pollution prevention exist in laboratory operation. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.

14.2 For information about pollution prevention that may be applicable to laboratories and research institutions consult *Less is Better: Laboratory Chemical management for Waste Reduction* available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th St., N.W. Washington, D.C. 20036, <http://www.acs.org>.

15.0 WASTE MANAGEMENT

The Environmental Protection Agency requires that laboratory waste management practices be conducted consistent with all applicable rules and regulations. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods and bench operations, complying with the letter and spirit of any sewer discharge permits and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management, consult *The Waste Management Manual for Laboratory Personnel* available from the American Chemical Society at the address listed in Sec. 14.2.

TABLE 2
RECOMMENDED ISOTOPES FOR SELECTED ELEMENTS

Element of Interest	Mass(es)
Aluminum	<u>27</u>
Antimony	121, <u>123</u>
Arsenic	<u>75</u>
Barium	138, 137, 136, <u>135</u> , 134
Beryllium	<u>9</u>
Bismuth (IS)	209
Cadmium	<u>114</u> , 112, <u>111</u> , 110, 113, 116, 106
Calcium (I)	42, 43, <u>44</u> , 46, 48
Chlorine (I)	35, 37, (77, 82) ^a
Chromium	<u>52</u> , <u>53</u> , <u>50</u> , 54
Cobalt	<u>59</u>
Copper	<u>63</u> , <u>65</u>
Germanium (IS)	74
Holmium (IS)	165
Indium (IS)	<u>115</u> , 113
Iron (I)	<u>56</u> , <u>54</u> , <u>57</u> , 58
Lanthanum (I)	139
Lead	<u>208</u> , <u>207</u> , <u>206</u> , 204
Lithium (IS)	6 ^b , 7
Magnesium (I)	24, <u>25</u> , <u>26</u>
Manganese	<u>55</u>
Mercury	202, <u>200</u> , 199, 201
Molybdenum (I)	98, 96, 92, <u>97</u> , 94, (108) ^a
Nickel	58, <u>60</u> , 62, <u>61</u> , 64
Potassium (I)	<u>39</u>
Rhodium (IS)	103
Scandium (IS)	45
Selenium	80, <u>78</u> , <u>82</u> , <u>76</u> , <u>77</u> , 74
Silver	<u>107</u> , <u>109</u>
Sodium (I)	<u>23</u>
Terbium (IS)	159
Thallium	<u>205</u> , 203
Vanadium	<u>51</u> , <u>50</u>
Tin (I)	120, <u>118</u>
Yttrium (IS)	89
Zinc	64, <u>66</u> , <u>68</u> , <u>67</u> , 70

^a These masses are also useful for interference correction (Sec. 4.2).

^b Internal standard must be enriched in the ⁶Li isotope. This minimizes interference from indigenous lithium.

NOTE: Method 6020 is recommended for only those analytes listed in Sec.1.2. Other elements are included in this table because they are potential interferents (labeled I) in the determination of recommended analytes, or because they are commonly used internal standards (labeled IS). Isotopes are listed in descending order of natural abundance. The most generally useful isotopes are underlined and in boldface, although certain matrices may require the use of alternative isotopes.

TABLE 3

EXAMPLE ICP-MS MULTI-LABORATORY PRECISION AND ACCURACY DATA
FOR AQUEOUS SOLUTIONS

Element	Comparability ^a Range	%RSD Range	N ^b	S ^c
Aluminum	95 - 100	11 - 14	14 - 14	4
Antimony	d	5.0 - 7.6	16 - 16	3
Arsenic	97 - 114	7.1 - 48	16 - 16	4
Barium	91 - 99	4.3 - 9.0	16 - 16	5
Beryllium	103 - 107	8.6 - 14	13 - 14	3
Cadmium	98 - 102	4.6 - 7.2	18 - 20	3
Calcium	99 - 107	5.7 - 23	17 - 18	5
Chromium	95 - 105	13 - 27	16 - 18	4
Cobalt	101 - 104	8.2 - 8.5	18 - 18	3
Copper	85 - 101	6.1 - 27	17 - 18	5
Iron	91 - 900	11 - 150	10 - 12	5
Lead	71 - 137	11 - 23	17 - 18	6
Magnesium	98 - 102	10 - 15	16 - 16	5
Manganese	95 - 101	8.8 - 15	18 - 18	4
Nickel	98 - 101	6.1 - 6.7	18 - 18	2
Potassium	101 - 114	9.9 - 19	11 - 12	5
Selenium	102 - 107	15 - 25	12 - 12	3
Silver	104 - 105	5.2 - 7.7	13 - 16	2
Sodium	82 - 104	24 - 43	9 - 10	5
Thallium	88 - 97	9.7 - 12	18 - 18	3
Vanadium	107 - 142	23 - 68	8 - 13	3
Zinc	93 - 102	6.8 - 17	16 - 18	5

Data obtained from Ref. 12.

^a Comparability refers to the percent agreement of mean ICP-MS values to those of the reference technique (ICP-AES or GFAA).

^b N is the range of the number of ICP-MS measurements where the analyte values exceed the limit of quantitation (3.3 times the average IDL value). A larger number gives a more reliable comparison.

^c S is the number of samples with results greater than the limit of quantitation.

^d No comparability values are provided for antimony because of evidence that the reference data is affected by an interference.

These data are provided for guidance purposes only.

TABLE 4

EXAMPLE ICP-MS MULTI-LABORATORY PRECISION AND ACCURACY DATA
FOR SOLID MATRICES

Element	Comparability ^a Range	%RSD Range	N ^b	S ^c
Aluminum	83 - 101	11 - 39	13 - 14	7

Revision: 21		Effective Date: This version
Section	Justification	Changes
Revision Log	Formatting requirement per 1-P-QM-QMA-9017356	Removed revision logs up to the previous version
Cross Reference	Reflect current procedure	Added reference Analysis #6142, 6123, 6125, 10801...
Scope	Clarification	Reworded section.
Sample Collection, Preservation and Handling	Reflect current procedure	Changed sample storage temperature to 0° to 6°C, but not frozen.
Reagents and Standards	Reflect current procedure	Added reference to 1-P-QM-FOR-9009182.
Procedure	Reflect current procedure	Add boiling stones to the batch blank and LCS for the fish samples.
Block Digester Instructions	Reflect current procedure No longer used	Hold and press the star key. Deleted test pertaining to the control panel grey buttons.
Quality Assurance/Quality Control	Reflect current procedure	Added reference to ICP/MS Analysis #6142, 6123, 6125, 10801, for batch requirements.

Revision: 20		Effective Date: Jan 22, 2013
Section	Justification	Changes
Revision Log	Formatting requirement per 1-P-QM-QMA-9017356	Removed revision logs up to the previous version
Throughout Document	Reflect re-identification of documents in EtQ	Replaced all prior Level 1, 2, 3, and 4 document numbers (analyses excluded) with EDR numbers
Safety Precautions and Waste Handling	Reflect current procedure	Added the use of designated dispensing equipment for HNO3 and HCL Added test pertaining to hazardous flags
Procedure	Reflects current procedure	Removed paint chip section. Deleted text pertaining to reducing the weight of paint chips. Paint chips will be digested as normal digestion per this procedure.
Procedure 2	Reflects current procedure	Added text pertaining to adding PTFE boiling stones to the LCS. Added text pertaining to entering the weights of the Blank and LCS in the LLENS.

1-P-QM-FOR-9009182	Working Instructions for Prep Solutions and Standards

Purpose:

This digestion procedure is for the preparation of solid samples for analysis by ICP and ICP/MS following SW-846 protocol.

Scope:

This method is used for preparation of metals in solid samples for analysis by ICP and ICP/MS.

Basic Principles:

A representative sample is digested with repeated additions of nitric acid (HNO₃) and hydrogen peroxide (H₂O₂). Hydrochloric acid (HCl) is added to the initial digestate and the sample is refluxed. The resultant digestate is diluted and analyzed.

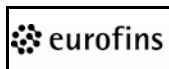

Revision: 21	Effective date: Mar 17, 2014	Page 3 of 13

--	--	---

This method is not a total digestion technique for most samples; it is a very strong acid digestion that dissolves almost all elements that could become “environmentally available.” By design, elements bound in silicate structures are not normally dissolved by this procedure.

Definitions:

1. ACS – American Chemical Society
2. D – Sample Duplicate
3. DOC – Demonstration of Capability
4. IDOC – Initial Demonstration of Capability
5. LCS/LCSD – Laboratory Control Sample/ Laboratory Control Sample Duplicate
6. LCSW– Laboratory Control Sample Water
7. LLENS - the computer program that integrates a PC with an analytical balance to collect data directly from the balance. The program organizes the data and transmits the readings to the LIMS.
8. LIMS – Laboratory Information Management Systems
9. LLI Sample ID – unique 7-digit number assigned to a client sample.
10. LOQ – Limit of Quantitation
11. MDL – Method Detection Limit
12. MS (R) – Matrix Spike
13. MSD (M) – Matrix spike duplicate

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
---	---	--

14. PB/PBW–Preparation Blank/ Preparation Blank Water
15. QC – Quality Control
16. Method Blank - equivalent to a Preparation Blank. A designated sample designed to monitor for sample contamination during the analysis process. A volume of reagent laboratory water is typically used to monitor water sample analysis, while solids blanks consist of a purified solid matrix or just the reagents used in the test. The blank demonstrates that no artifacts were introduced during the analysis process.
17. SOP- Standard Operating Procedure
18. U or US – unspiked background sample

Interferences:

When analyzing sample by ICP-MS using this digestion procedure we follow the instrument manufacturer’s guidelines to eliminate polyatomic interferences typically caused by Chlorine. The process we follow involves the use of a collision/reaction cell on the ICP-MS. Below is a description of how the collision/reaction cell works.

Reaction Process - The primary method of interference removal is through a reaction event. When using a reaction gas, either the target interference is more reactive than the target analyte, leading to preferential removal of the interferent or (less commonly) the target analyte is more reactive and is converted to a new species at a different mass which is free from any existing or newly-formed overlap

Collision Process - The primary method of interference removal is through a non-reactive event. This process of interference removal is kinetic energy discrimination (KED). Energy Discrimination is most commonly used with an inert gas, which means the interference removal process is not affected by reactions in the cell.

Safety Precautions and Waste Handling:

All laboratory waste is accumulated, managed, and disposed of in accordance with all federal, state and local laws and regulations.

See *Chemical Hygiene Plan* for general information regarding employee safety, waste management, and pollution prevention.

Preparing samples for inorganic analysis involves working with concentrated acids and other chemicals which are dangerous if not handled carefully:

Nitric acid (HNO₃) – This acid can cause skin burns. Add nitric acid to samples in a hood or use the designated dispensing equipment to avoid exposure to toxic fumes.

Hydrochloric acid (HCl) – This acid can cause skin burns. Never mix HCl with concentrated H₂SO₄ to avoid a violent reaction. Always use in a fume hood or use the designated dispensing equipment.

Hydrogen peroxide (H₂O₂) - This is a strong oxidizing agent and causes severe burns. Avoid contact with skin.

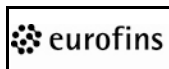

When diluting strong acids, never add water to acid; always add acid to water.

Store concentrated acids in the prep room acid lockers. Only acids are to be stored in these lockers. (Store solvents in the flammable liquid storage cabinet.) Some concentrated acids are kept in the acid reagent bottles on prep room counters. Fill reagent bottles in an operating fume hood using caution to avoid spills.

Perform acid digestions in hoods that are turned on and have active alarms. Notify a supervisor immediately if the hood is malfunctioning or the alarm sounds.

Samples that contain dust may be hazardous. Open in a fume hood.

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
---	--	--

When a hazardous flag is added indicating possible cyanide, special precautions are required to avoid exposure to hydrogen cyanide gas. Contact your supervisor prior to adding acid. Always open these samples and add the acid in a hood.

Use spill pillows to absorb large acid spills (small spills are cleaned with wet paper towels.) Use SPILL-X-A powder or equivalent to neutralize any remaining acid and then rinse the area thoroughly with water. Spill pillows and SPILL-X-A are stored on the prep room shelf.

Dispose of acid waste properly. Collect all acid digestions, waste solutions, and expired reagent solutions in waste containers. When the acid waste containers are full, a designated acid waste handler transfers the waste to the acid neutralization tank.

Personnel Training and Qualifications:

All personnel performing this procedure must have documentation of reading, understanding, and agreeing to follow the current version of this SOP and a documented Demonstration of Capability (DOC).

Initially, each employee performing this digestion procedure must work with an experienced employee for a period of time until they can independently set up batches and perform the necessary steps outlined in this procedure. Proficiency is measured through documentation of the critical steps in this procedure, over checking of data as well as an IDOC.

The IDOC and the DOC consists of four laboratory control samples that are carried through all steps of the analysis and meet the defined acceptance criteria. The criteria include the calculation of mean accuracy and standard deviation.

Sample Collection, Preservation, and Handling:

Solid samples require no chemical preservation.

Samples must be submitted in glass or plastic containers and stored at 0° to 6°C, but not frozen, prior to digestion. Samples must be digested within 6 months (180 days) of sample collection.

--	---	--

Digested samples are stored in polypropylene bottles at room temperature.

Apparatus and Equipment:

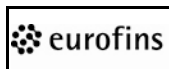

1. Polypropylene containers and covers (digestion vessels) - certified clean and Class A equivalent
2. Whatman No. 41 filter paper or equivalent
3. Funnels
4. Environmental Express HotBlock (block digester) - adjustable and capable of maintaining a temperature of 90 to 95°C
5. Balance capable of reading 0.01 g
6. Chemware Ultra-Pure PTFE boiling stones, or equivalent.
7. Computer and software LLENS (Lancaster Laboratories Electronic Notebook System)

Reagents and Standards:

For reagent preparation, shelf life, and storage conditions, see Form 1-P-QM-FOR-9009182.

1. Nitric acid (HNO₃) – Fisher, Trace Metal Grade, or equivalent. Store at room temperature. Re-evaluate annually.
2. Nitric acid (1:1) – Add 500 mL of HNO₃ to 500 mL of reagent water. Store in polypropylene at room temperature. Expires 6 months from date of preparation. (Different volumes are acceptable but ratios must stay the same.)

Revision: 21	Effective date: Mar 17, 2014	Page 8 of 13

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
---	---	--

3. Hydrogen peroxide, 30% (H₂O₂) – Fisher, Certified ACS or equivalent. Store at room temperature. Re-evaluate annually.
4. Hydrochloric acid (HCl) – Baker Instra-Analyzed, or equivalent. Store at room temperature. Re-evaluate annually.

NOTE: It is acceptable to prepare using multiples of indicated weights and volumes if ratios are maintained.

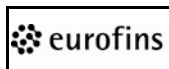

Calibration:

Not applicable.

Procedure:

1. Turn block digestor on and allow block to reach the Control Point setting that provides 90° to 95°C sample temperature. (The block temperature setting is not necessarily the sample temperature.) See below for **Block Digestor Instructions** section.
2. Weigh 1.00 to 1.05 g (to the nearest 0.01 g) of a well mixed sample into a polypropylene digestion vessel. (If the sample is watery use 5.00 to 5.05 grams for analysis. Additional information on non-standard matrices is found at the end of the procedure section.) Add 1.00 to 1.49 g of Chemware Ultra-Pure PTFE boiling stones to the digestion vessel for the blank and LCS. Enter the blank and LCS weight as 1.0000 to 100.0000 final volume in the LLENS. For sample batch spiking procedures see 1-P-QM-FOR-9009182. All spiking must be performed prior to starting the digestion procedure.
3. Add 10 mL of (1:1) HNO₃, swirl to mix, and cover with a polypropylene cover.
4. Place sample vessel in block digestor. Heat (reflux) the sample at 90° to 95°C for 10 to 15 minutes without boiling.
5. Remove vessel from digestion block and allow sample to cool.

Revision: 21	Effective date: Mar 17, 2014	Page 9 of 13
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
--	---	--

6. Add 5 mL of concentrated HNO₃. Replace cover, return vessel to digestion block and heat for 30 minutes.

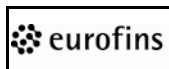

NOTE: If brown fumes are generated (indicating oxidation of the sample by HNO₃) continue the process of adding 5 mL HNO₃ and heating until no brown fumes are given off by the sample. This indicates that the reaction with HNO₃ is complete. Add the same amount of HNO₃ to the entire digestion batch.

7. With cover on, heat at 90° to 95°C without boiling for 2 hours. Maintain a covering of solution over the bottom of the vessel at all times (add reagent water if necessary).
8. Remove vessel from digestion block and allow sample to cool.
9. Add 2 mL of reagent water and 3 mL of 30% H₂O₂. With cover on, return vessel to digestion block and heat until effervescence subsides. Care must be taken to ensure that losses do not occur due to excessively vigorous effervescence.
10. Continue to add 30% H₂O₂ in 1-mL aliquots with warming until the effervescence is minimal or until the general sample appearance is unchanged.

NOTE: Do not add more than a total of 10 mL 30% H₂O₂.

11. With cover on, continue heating the acid-peroxide digestate at 90° to 95°C without boiling for 2 hours. Maintain a covering of solution over the bottom of the vessel at all times (add reagent water if necessary).
12. Remove sample vessel from digestion block and allow to cool.
13. Add 10 mL of HCl. With the cover on, return vessel to digestion block and heat at 90° to 95°C for 15 minutes.

Revision: 21	Effective date: Mar 17, 2014	Page 10 of 13
COMPANY CONFIDENTIAL		

 Lancaster Laboratories Environmental	Document Title: Sample Prep of Sediments, Sludges, Soils, and Fish Tissue for Analysis of Metals by ICP and ICP-MS	Eurofins Document Reference: 1-P-QM-WI -9015160
---	---	--

14. Remove sample vessel from digestion block.
15. If floating particulate is evident after digestion, the sample must be filtered.
 - a. Filter through Whatman No. 41 filter paper into a polypropylene container.
 - b. Wash sample vessel, residue, and paper thoroughly with reagent water.
 - c. If any samples are filtered, the prep blank and LCS must also be filtered.
16. Adjust volume to the 100mL mark on the digestion vessel with reagent water and mix. Seal vessel with a screw cap. The sample is now ready for analysis.

NOTE: When special limits of quantitation are required by the client, use more sample weight.

For wipe samples:

When wipes are digested by this method, one blank media each must be used for the batch preparation blank, the laboratory control sample (LCS), and the laboratory control sample duplicate (LCSD). Refer to Form 1-P-QM-FOR-9009182 for the spiking of the LCS and LCSD. Digest wipes in their own batch. Use reagent water to rinse any particulate matter from the wipe container into the vessel containing the wipe before digesting. If brown fumes are evolved during wipe sample digestion, perform only two 5 mL HNO₃ additions with 30-minute refluxing each; add the same amount of HNO₃ to the entire batch. Proceed with digestion.

For fish tissue samples:

When fish tissues are digested by this method, refer to Form 1-P-QM-FOR-9009182 for the spiking of the LCS, LCSD (if needed), R (matrix spike), and M (matrix spike duplicate). Add 1.00 to 1.49 g of Chemware Ultra-Pure PTFE boiling stones to the digestion vessel for the blank and LCS. Digest fish tissues in their own batch.

--	---	--

Block Digester Instructions:

1. Turn block digester on by pressing rocker switch located on the cord.
2. Wait about 8 seconds until controller display indicates current block temperature.
3. PRESS and hold STAR (*) key.
4. The display shows Control Point temperature.
5. The digits can be changed to the desired value by pressing the up and down arrow keys while holding the (*) key.
6. Confirm Control Point temperature is set to the block temperature that provides 90° to 95°C.

NOTE: See HotBlock Control Point Temperature Logbook to obtain control point temperature setting for the HotBlock being used. If necessary, adjust Control Point temperature to the proper setting as instructed below.

NOTE: Polypropylene containers must not be heated above 130°C.

Calculations:

Not applicable

Statistical Information/Method Performance:

Not applicable to this procedure. See analysis method.

Quality Assurance/Quality Control:

For sample batch spiking instructions see form 1-P-QM-FOR-9009182. Refer to ICP section when prepping ICP analysis. Refer to ICP/MS section when prepping ICP/MS analysis. Prepare a method blank, sample duplicate, sample matrix spike, sample matrix spike duplicate, and laboratory control sample with every digestion batch (20 samples or less). Each piece of batch QC is digested following the procedure in this SOP. If any samples are filtered the prep blank and LCS must also be filtered.

Refer to ICP Analysis #6966, 1643, 6935, ... for sample batch quality control requirements, acceptance criteria and corrective action.

Refer to ICP/MS Analysis #6142, 6123, 6125, 10801, 6126, ... for sample batch quality control requirements, acceptance criteria and corrective action.

Introduction

Method 1631 (the "Method") supports technology-based and water quality-based monitoring programs authorized under the Clean Water Act (CWA; the "Act").

CWA Sections 301 and 306 require EPA to publish effluent standards that restrict the direct discharge of pollutants to the nations waters, and CWA Sections 307(b) and (c) require EPA to promulgate nationally applicable pretreatment standards which restrict pollutant discharges into sewers flowing to publicly owned treatment works (POTWs). The effluent limitations guidelines are published at CFR parts 401-503.

CWA Section 303 requires each State to set a water quality standard for each body of water within its boundaries. A State water quality standard consists of a designated use or uses of a water body or a segment of a water body, the water quality criteria that are necessary to protect the designated use or uses, and an antidegradation policy. CWA Section 304(a) requires EPA to publish water quality criteria that reflect the latest scientific knowledge concerning the physical fate of pollutants, the effects of pollutants on ecological and human health, and the effect of pollutants on biological community diversity, productivity, and stability. These water quality standards serve two purposes: (1) they establish the water quality goals for a specific water body, and (2) they are the basis for establishing water quality-based treatment controls and strategies beyond the technology-based controls required by CWA Sections 301(b) and 306.

In 1987, amendments to the CWA required States to adopt numeric criteria for toxic pollutants (designated in Section 307(a) of the Act) based on EPA Section 304(a) criteria or other scientific data, when the discharge or presence of those toxic pollutants could reasonably be expected to interfere with designated uses. Method 1631 was specifically developed to provide reliable measurements of mercury at EPA WQC levels.

In developing methods for determination of trace metals, EPA found that one of the greatest difficulties was precluding sample contamination during collection, transport, and analysis. The degree of difficulty, however, is highly dependent on the metal and site-specific conditions. Method 1631 is designed to preclude contamination in nearly all situations. It also contains procedures necessary to produce reliable results at the lowest WQC levels published by EPA. In recognition of the variety of situations to which this Method may be applied, and in recognition of continuing technological advances, Method 1631 is performance based. Alternative procedures may be used so long as those procedures are demonstrated to yield reliable results.

Requests for additional copies of this draft Method should be directed to:

U.S. EPA Sample Control Center
6101 Stevenson Avenue
Alexandria, VA 22304-3540
703/461-2100

Note: This Method is performance based. The laboratory is permitted to omit steps or modify procedures provided that all performance requirements in this Method are met. The laboratory must not omit or modify any procedure defined by the term “shall” or “must” and must perform all quality control tests.

Method 1631, Revision E

Mercury in Water by Oxidation, Purge and Trap, and Cold Vapor Atomic Fluorescence Spectrometry

1.0 Scope and Application

- 1.1 Method 1631, Revision E (the "Method") is for determination of mercury (Hg) in filtered and unfiltered water by oxidation, purge and trap, desorption, and cold-vapor atomic fluorescence spectrometry (CVAFS). This Method is for use in EPA's data gathering and monitoring programs associated with the Clean Water Act, the Resource Conservation and Recovery Act, the Comprehensive Environmental Response, Compensation and Liability Act, and the Safe Drinking Water Act. The Method is based on a contractor-developed procedure (Reference 16.1) and on peer-reviewed, published procedures for the determination of mercury in aqueous samples, ranging from sea water to sewage effluent (References 16.2–16.5).
- 1.2 This Method is accompanied by Method 1669: *Sampling Ambient Water for Determination of Trace Metals at EPA Water Quality Criteria Levels* (Sampling Method). The Sampling Method guidance document is recommended to preclude contamination during the sampling process.
- 1.3 This Method is for determination of Hg in the range of 0.5–100 ng/L. Application may be extended to higher levels by selection of a smaller sample size or by calibration of the analytical system across a higher range. For measurement of blank samples, the Method may be extended to a lower level by calibration to a lower calibration point. Section 10.4 gives requirements for extension of the calibration range.
- 1.4 The ease of contaminating ambient water samples with mercury and interfering substances cannot be overemphasized. This Method includes suggestions for improvements in facilities and analytical techniques that should minimize contamination and maximize the ability of the laboratory to make reliable trace metals determinations. Certain sections of this Method contain suggestions and other sections contain requirements to minimize contamination.
- 1.5 The detection limit and minimum level of quantitation in this Method usually are dependent on the level of interferences rather than instrument limitations. The method detection limit (MDL; 40 CFR 136, Appendix B) for Hg has been determined to be 0.2 ng/L when no interferences are present. The minimum level of quantitation (ML) has been established as 0.5 ng/L. An MDL as low as 0.05 ng/L can be achieved for low Hg samples by using a larger sample volume, a lower BrCl level (0.2%), and extra caution in sample handling.
- 1.6 Clean and ultraclean—The terms "clean" and "ultraclean" have been applied to the techniques needed to reduce or eliminate contamination in trace metals determinations. These terms are not used in this Method because they lack an exact definition. However, the information provided in this Method is consistent with the summary guidance on clean and ultraclean techniques (References 16.6-16.7).
- 1.7 This Method follows the EPA Environmental Methods Management Council's "Guidelines and Format for Methods to Be Proposed at 40 CFR, part 136 or part 141."

- 1.8 This Method is "performance based." The laboratory is permitted to modify the Method to overcome interferences or lower the cost of measurements if all performance criteria are met. Section 9.1.2.1 gives the requirements for establishing method equivalency.
- 1.9 Any modification of this Method, beyond those expressly permitted, shall be considered a major modification subject to application and approval of alternate test procedures under 40 CFR 136.4 and 136.5.
- 1.10 This Method should be used only by analysts experienced in the use of CVAFS techniques and who are trained thoroughly in the sample handling and instrument techniques described in this Method. Each laboratory that uses this Method must demonstrate the ability to generate acceptable results using the procedures in Section 9.2.
- 1.11 This Method is accompanied by a data verification and validation guidance document, *Guidance on the Documentation and Evaluation of Trace Metals Data Collected for CWA Compliance Monitoring* (Reference 16.8), that can be used for verification and validation of the data obtained.
- 1.12 This Method uses either a bubbler or flow-injection system for determination of mercury in water. Separate calibration, analysis, and calculation procedures are provided for a bubbler system (Sections 10.2, 11.2.1, and 12.2) and for a flow-injection system (Sections 10.3, 11.2.2, and 12.3).

2.0 Summary of Method

- 2.1 A 100- to 2000-mL sample is collected directly into a cleaned, pretested, fluoropolymer or glass bottle using sample handling techniques designed for collection of mercury at trace levels (Reference 16.9).
- 2.2 For dissolved Hg, the sample is filtered through a 0.45- μ m capsule filter prior to preservation.
- 2.3 The sample is preserved by adding either pretested 12N hydrochloric acid (HCl) or bromine monochloride (BrCl) solution. If a sample will also be used for the determination of methyl mercury, it should be preserved according to procedures in the method that will be used for determination of methylmercury.
- 2.4 Prior to analysis, all Hg in a 100-mL sample aliquot is oxidized to Hg(II) with BrCl.
- 2.5 After oxidation, the sample is sequentially reduced with $\text{NH}_2\text{OH}\cdot\text{HCl}$ to destroy the free halogens, then reduced with stannous chloride (SnCl_2) to convert Hg(II) to volatile Hg(0).
- 2.6 The Hg(0) is separated from solution either by purging with nitrogen, helium, or argon, or by vapor/liquid separation. The Hg(0) is collected onto a gold trap (Figures 1, 2, and 3).
- 2.7 The Hg is thermally desorbed from the gold trap into an inert gas stream that carries the released Hg(0) to a second gold (analytical) trap. The Hg is desorbed from the analytical trap into a gas stream that carries the Hg into the cell of a cold-vapor atomic fluorescence spectrometer (CVAFS) for detection (Figures 2 and 3).
- 2.8 Quality is assured through calibration and testing of the oxidation, purging, and detection systems.

3.0 Definitions

- 3.1 Total mercury—all BrCl-oxidizable mercury forms and species found in an unfiltered aqueous solution. This includes, but is not limited to, Hg(II), Hg(0), strongly organo-complexed Hg(II) compounds, adsorbed particulate Hg, and several tested covalently bound organo-mercurials (e.g., CH₃HgCl, (CH₃)₂Hg, and C₆H₅HgOOCCH₃). The recovery of Hg bound within microbial cells may require the additional step of UV photo-oxidation. In this Method, total mercury and total recoverable mercury are synonymous.
- 3.2 Dissolved mercury—all BrCl-oxidizable mercury forms and species found in the filtrate of an aqueous solution that has been filtered through a 0.45- μ m filter.
- 3.3 Apparatus—Throughout this Method, the sample containers, sampling devices, instrumentation, and all other materials and devices used in sample collection, sample processing, and sample analysis that come in contact with the sample and therefore require careful cleaning will be referred to collectively as the Apparatus.
- 3.4 Definitions of other terms used in this Method are given in the glossary (Section 17.0).

4.0 Contamination and Interferences

- 4.1 Preventing samples from becoming contaminated during the sampling and analysis process constitutes one of the greatest difficulties encountered in trace metals determinations. Over the last two decades, marine chemists have come to recognize that much of the historical data on the concentrations of dissolved trace metals in seawater are erroneously high because the concentrations reflect contamination from sampling and analysis rather than ambient levels. Therefore, it is imperative that extreme care be taken to avoid contamination when collecting and analyzing samples for trace metals.
- 4.2 Samples may become contaminated by numerous routes. Potential sources of trace metals contamination during sampling include: metallic or metal-containing labware (e.g., talc gloves that contain high levels of zinc), containers, sampling equipment, reagents, and reagent water; improperly cleaned or stored equipment, labware, and reagents; and atmospheric inputs such as dirt and dust. Even human contact can be a source of trace metals contamination. For example, it has been demonstrated that dental work (e.g., mercury amalgam fillings) in the mouths of laboratory personnel can contaminate samples directly exposed to exhalation (Reference 16.9).
- 4.3 Contamination Control
- 4.3.1 Philosophy—The philosophy behind contamination control is to ensure that any object or substance that contacts the sample is metal free and free from any material that may contain mercury.
- 4.3.1.1 The integrity of the results produced cannot be compromised by contamination of samples. This Method and the Sampling Method give requirements and suggestions for control of sample contamination.

- 4.3.1.2 Substances in a sample cannot be allowed to contaminate the laboratory work area or instrumentation used for trace metals measurements. This Method gives requirements and suggestions for protecting the laboratory.
- 4.3.1.3 Although contamination control is essential, personnel health and safety remain the highest priority. The Sampling Method and Section 5 of this Method give suggestions and requirements for personnel safety.
- 4.3.2 Avoiding contamination—The best way to control contamination is to completely avoid exposure of the sample to contamination in the first place. Avoiding exposure means performing operations in an area known to be free from contamination. Two of the most important factors in avoiding/reducing sample contamination are (1) an awareness of potential sources of contamination and (2) strict attention to work being done. Therefore, it is imperative that the procedures described in this Method be carried out by well-trained, experienced personnel.
- 4.3.3 Use a clean environment—The ideal environment for processing samples is a class-100 clean room. If a clean room is not available, all sample preparation should be performed in a class-100 clean bench or a nonmetal glove box fed by mercury- and particle-free air or nitrogen. Digestion should be performed in a nonmetal fume hood equipped with HEPA filtration and ideally situated in a clean room.
- 4.3.4 Minimize exposure—The Apparatus that will contact samples, blanks, or standard solutions should be opened or exposed only in a clean room, clean bench, or glove box so that exposure to an uncontrolled atmosphere is minimized. When not being used, the Apparatus should be covered with clean plastic wrap, stored in the clean bench or in a plastic box or glove box, or bagged in clean zip-type bags. Minimizing the time between cleaning and use will also minimize contamination.
- 4.3.5 Clean work surfaces—Before a given batch of samples is processed, all work surfaces in the hood, clean bench, or glove box in which the samples will be processed should be cleaned by wiping with a lint-free cloth or wipe soaked with reagent water.
- 4.3.6 Wear gloves—Sampling personnel must wear clean, non-talc gloves during all operations involving handling of the Apparatus, samples, and blanks. Only clean gloves may touch the Apparatus. If another object or substance is touched, the glove(s) must be changed before again handling the Apparatus. If it is even suspected that gloves have become contaminated, work must be halted, the contaminated gloves removed, and a new pair of clean gloves put on. Wearing multiple layers of clean gloves will allow the old pair to be quickly stripped with minimal disruption to the work activity.
- 4.3.7 Use metal-free Apparatus—All Apparatus used for determination of mercury at ambient water quality criteria levels must be nonmetallic, free of material that may contain metals, or both.
 - 4.3.7.1 Construction materials—Only fluoropolymer or glass containers must be used for collection of samples that will be analyzed for mercury because mercury vapors can diffuse in or out of other materials, leading to results that are biased low or high. Polyethylene and/or polypropylene labware may be used for digestion and other purposes because the time of sample exposure to these materials is relatively short. All materials, regardless of construction, that will directly or

indirectly contact the sample, must be known to be clean and free of Hg at the levels specified in this Method before proceeding.

- 4.3.7.2 **Serialization**—It is recommended that serial numbers be indelibly marked or etched on each piece of reusable Apparatus so that contamination can be traced, and logbooks should be maintained to track the sample from the container through the labware to introduction into the instrument. It may be useful to dedicate separate sets of labware to different sample types; e.g., receiving waters vs. effluents. However, the Apparatus used for processing blanks and standards must be mixed with the Apparatus used to process samples so that contamination of all labware can be detected.
- 4.3.7.3 The laboratory or cleaning facility is responsible for cleaning the Apparatus used by the sampling team. If there are any indications that the Apparatus is not clean when received by the sampling team (e.g., ripped storage bags), an assessment of the likelihood of contamination must be made. Sampling must not proceed if it is possible that the Apparatus is contaminated. If the Apparatus is contaminated, it must be returned to the laboratory or cleaning facility for proper cleaning before any sampling activity resumes.
- 4.3.8 **Avoid sources of contamination**—Avoid contamination by being aware of potential sources and routes of contamination.
- 4.3.8.1 **Contamination by carryover**—Contamination may occur when a sample containing a low concentration of mercury is processed immediately after a sample containing a relatively high concentration of mercury. The Hg concentration at which the analytical system (purge, traps, detector) will carry greater than 0.5 ng/L of Hg into a succeeding bubbler or system blank must be determined by analyzing calibration solutions containing successively larger concentrations of Hg. This test must be run prior to first use of the analytical system and whenever a change is made that would increase the amount of carryover. When a sample contains $\frac{1}{2}$ or greater of this determined Hg concentration, a bubbler blank (bubbler system) or system blank (flow injection system) must be analyzed to demonstrate no carryover at the blank criteria level. For the bubbler system, the blank must be run using the same bubbler and sample trap used to run the high concentration sample. Samples analyzed following a sample that has been determined to result in carryover must be reanalyzed. Samples that are known or suspected to contain the lowest concentration of mercury should be analyzed first followed by samples containing higher levels.
- 4.3.8.2 **Contamination by samples**—Significant laboratory or instrument contamination may result when untreated effluents, in-process waters, landfill leachates, and other undiluted samples containing concentrations of mercury greater than 100 ng/L are processed and analyzed. Samples known or suspected to contain Hg concentrations greater than 100 ng/L should be diluted prior to bringing them into the clean room or laboratory dedicated for processing trace metals samples.
- 4.3.8.3 **Contamination by indirect contact**—Apparatus that may not directly come in contact with the samples may still be a source of contamination. For example, clean tubing placed in a dirty plastic bag may pick up contamination from the bag and subsequently transfer the contamination to the sample. It is imperative that every piece of the Apparatus that is directly or indirectly used in the collection, processing, and analysis of water samples be thoroughly cleaned (Section 6.1.2).

- 4.3.8.4 Contamination by airborne particulate matter—Less obvious substances capable of contaminating samples include airborne particles. Samples may be contaminated by airborne dust, dirt, particles, or vapors from unfiltered air supplies; nearby corroded or rusted pipes, wires, or other fixtures; or metal-containing paint. Whenever possible, sample processing and analysis should occur as far as possible from sources of airborne contamination.
- 4.3.8.5 Contamination from reagents— Contamination can be introduced into samples from method reagents used during processing and analysis. Reagent blanks must be analyzed for contamination prior to use (see Section 9.4.3). If reagent blanks are contaminated, a new batch of reagents must be prepared (see Section 9.4.3.2).

4.4 Interferences

- 4.4.1 At the time of promulgation of this Method, gold and iodide were known interferences. At a mercury concentration of 2.5 ng/L and at increasing iodide concentrations from 30 to 100 mg/L, test data have shown that mercury recovery will be reduced from 100 to 0 percent. At iodide concentrations greater than 3 mg/L, the sample should be pre-reduced with SnCl₂ (to remove the brown color) and additional or more concentrated SnCl₂ should be added. To preclude loss of Hg, the additional SnCl₂ should be added in a closed vessel or analysis should proceed immediately. If samples containing iodide concentrations greater than 30 mg/L are analyzed, it may be necessary to clean the analytical system with 4N HCl after the analysis (Reference 16.10).
- 4.4.2 The potential exists for destruction of the gold traps if free halogens are purged onto them, or if they are overheated (>500 °C). When the instructions in this Method are followed, neither of these outcomes is likely.
- 4.4.3 Water vapor may collect in the gold traps and subsequently condense in the fluorescence cell upon desorption, giving a false peak due to scattering of the excitation radiation. Condensation can be avoided by predrying the gold trap. Traps that tend to absorb large quantities of water vapor should not be used.
- 4.4.4 The fluorescent intensity is strongly dependent upon the presence of molecular species in the carrier gas that can cause "quenching" of the excited atoms. The dual amalgamation technique eliminates quenching due to trace gases, but it remains the laboratory's responsibility to ensure high purity inert carrier gas and a leak-free analytical train.

5.0 Safety

- 5.1 The toxicity or carcinogenicity of each chemical used in this Method has not been precisely determined; however, each compound should be treated as a potential health hazard. Exposure to these compounds should be reduced to the lowest possible level.
 - 5.1.1 Chronic mercury exposure may cause kidney damage, muscle tremors, spasms, personality changes, depression, irritability and nervousness. Organo-mercurials may cause permanent brain damage. Because of the toxicological and physical properties of Hg, pure standards should be handled only by highly trained personnel thoroughly familiar with handling and cautionary procedures and the associated risks.

- 5.1.2 It is recommended that the laboratory purchase a dilute standard solution of the Hg in this Method. If primary solutions are prepared, they shall be prepared in a hood, and a NIOSH/MESA-approved toxic gas respirator shall be worn.
- 5.2 This Method does not address all safety issues associated with its use. The laboratory is responsible for maintaining a current file of OSHA regulations for safe handling of the chemicals specified in this Method. OSHA rules require that a reference file of material safety data sheets (MSDSs) must be made available to all personnel involved in these analyses (29 CFR 1917.28, Appendix E). It also is suggested that the laboratory perform personal hygiene monitoring of each analyst who uses this Method and that the results of this monitoring be made available to the analyst. Personal hygiene monitoring should be performed using OSHA or NIOSH approved personal hygiene monitoring methods. Additional information on laboratory safety can be found in References 16.11-16.14. The references and bibliography included in Reference 16.14 are particularly comprehensive in dealing with the general subject of laboratory safety.
- 5.3 Samples suspected to contain concentrations of Hg at $\mu\text{g/L}$ or higher levels are handled using essentially the same techniques employed in handling radioactive or infectious materials. Well-ventilated, controlled access laboratories are required. Assistance in evaluating the health hazards of particular laboratory conditions may be obtained from certain consulting laboratories and from State Departments of Health or Labor, many of which have an industrial health service. Each laboratory must develop a safety program for handling Hg.
- 5.3.1 Facility—When samples known or suspected of containing high concentrations of mercury are handled, all operations (including removal of samples from sample containers, weighing, transferring, and mixing) should be performed in a glove box demonstrated to be leak-tight or in a fume hood demonstrated to have adequate airflow. Gross losses to the laboratory ventilation system must not be allowed. Handling of the dilute solutions normally used in analytical and animal work presents no inhalation hazards except in an accident.
- 5.3.2 Protective equipment—Disposable plastic gloves, apron or lab coat, safety glasses or mask, and a glove box or fume hood adequate for radioactive work should be used. During analytical operations that may give rise to aerosols or dusts, personnel should wear respirators equipped with activated carbon filters.
- 5.3.3 Training—Workers must be trained in the proper method of removing contaminated gloves and clothing without contacting the exterior surfaces.
- 5.3.4 Personal hygiene—Hands and forearms should be washed thoroughly after each manipulation and before breaks (coffee, lunch, and shift).
- 5.3.5 Confinement—Isolated work areas posted with signs, segregated glassware and tools, and plastic absorbent paper on bench tops will aid in confining contamination.
- 5.3.6 Effluent vapors—The effluent from the CVAFS should pass through either a column of activated charcoal or a trap containing gold or sulfur to amalgamate or react mercury vapors.
- 5.3.7 Waste handling—Good technique includes minimizing contaminated waste. Plastic bag liners should be used in waste cans. Janitors and other personnel must be trained in the safe handling of waste.
- 5.3.8 Decontamination

- 5.3.8.1 Decontamination of personnel—Use any mild soap with plenty of scrubbing action.
- 5.3.8.2 Glassware, tools, and surfaces—Sulfur powder will react with Hg to produce mercuric sulfide, thereby eliminating the possible volatilization of Hg. Satisfactory cleaning may be accomplished by dusting a surface lightly with sulfur powder, then washing with any detergent and water.
- 5.3.9 Laundry—Clothing known to be contaminated should be collected in plastic bags. Persons that convey the bags and launder the clothing should be advised of the hazard and trained in proper handling. If the launderer knows of the potential problem, the clothing may be put into a washer without contact. The washer should be run through a cycle before being used again for other clothing.
- 5.3.10 Wipe tests—A useful method of determining cleanliness of work surfaces and tools is to wipe the surface with a piece of filter paper. Extraction and analysis by this Method can achieve a limit of detection of less than 1 ng per wipe. Less than 0.1 µg per wipe indicates acceptable cleanliness; anything higher warrants further cleaning. More than 10 µg on a wipe constitutes an acute hazard and requires prompt cleaning before further use of the equipment or work space, and indicates that unacceptable work practices have been employed.

6.0 Apparatus and Materials

Disclaimer: The mention of trade names or commercial products in this Method is for illustrative purposes only and does not constitute endorsement or recommendation for use by the Environmental Protection Agency. Equivalent performance may be achievable using apparatus, materials, or cleaning procedures other than those suggested here. The laboratory is responsible for demonstrating equivalent performance.

6.1 Sampling equipment

- 6.1.1 Sample collection bottles—fluoropolymer or glass, 125- to 1000-mL, with fluoropolymer or fluoropolymer-lined cap.
- 6.1.2 Cleaning
 - 6.1.2.1 New bottles are cleaned by heating to 65–75 °C in 4 N HCl or concentrated HNO₃ for at least 48 h. The bottles are cooled, rinsed three times with reagent water, and filled with reagent water containing 1% HCl. These bottles are capped and placed in a clean oven at 60–70°C overnight. After cooling, they are rinsed three more times with reagent water, filled with reagent water containing 0.4% (v/v) HCl, and placed in a mercury-free Class-100 clean bench until the outside surfaces are dry. The bottles are tightly capped (with a wrench), double-bagged in new polyethylene zip-type bags until needed, and stored in wooden or plastic boxes until use. The bottles may be shipped to the sampling site containing dilute HCl solution (e.g., 0.04%), containing reagent water, or empty.
 - 6.1.2.2 Used bottles known not to have contained mercury at high (>100 ng/L) levels are cleaned as above, except for only 6–12 h in hot 4 N HCl.

- 6.1.2.3 Bottle blanks must be analyzed as described in Section 9.4.7. To verify the effectiveness of the cleaning procedures, bottle blanks must be demonstrated to be free of mercury at the ML of this Method.
- 6.1.2.4 As an alternative to cleaning by the laboratory, bottles may be purchased from a commercial supplier and each lot certified to be clean. Bottles from the lot must be tested as bottle blanks (Section 9.4.7) and demonstrated to be free of mercury at the ML of this Method. If mercury is present above this level in any bottle, either the lot must be rejected or the bottles must be re-cleaned.
- 6.1.3 Filtration Apparatus
- 6.1.3.1 Filter—0.45- μm , 15-mm diameter capsule filter (Gelman Supor 12175, or equivalent)
- 6.1.3.2 Peristaltic pump—115-V a.c., 12-V d.c., internal battery, variable-speed, single-head (Cole-Parmer, portable, "Masterflex L/S," Catalog No. 07570-10 drive with Quick Load pump head, Catalog No. 07021-24, or equivalent).
- 6.1.3.3 Tubing—styrene/ethylene/butylene/silicone (SEBS) resin for use with peristaltic pump, approx 3/8-in ID by approximately 3 ft (Cole-Parmer size 18, Catalog No. 06424-18, or approximately 1/4-in OD, Cole-Parmer size 17, Catalog No. 06424-17, or equivalent). Tubing is cleaned by soaking in 5–10% HCl solution for 8–24 h, rinsing with reagent water in a clean bench in a clean room, and drying in the clean bench by purging with metal-free air or nitrogen. After drying, the tubing is double-bagged in clear polyethylene bags, serialized with a unique number, and stored until use.
- 6.2 Equipment for bottle and glassware cleaning
- 6.2.1 Vat, 100–200 L, high-density polyethylene (HDPE), half filled with 4 N HCl in reagent water.
- 6.2.2 Panel immersion heater, 500-W, all-fluoropolymer coated, 120 vac (Cole-Parmer H-03053-04, or equivalent)
-
- WARNING:** *Read instructions carefully!! The heater will maintain steady state, without temperature feedback control, of 60–75°C in a vat of the size described. However, the equilibrium temperature will be higher (up to boiling) in a smaller vat. Also, the heater plate MUST be maintained in a vertical position, completely submerged and away from the vat walls to avoid melting the vat or burning out!*
-
- 6.2.3 Laboratory sink—in Class-100 clean area, with high-flow reagent water (Section 7.1) for rinsing.
- 6.2.4 Clean bench—Class-100, for drying rinsed bottles.
- 6.2.5 Oven—stainless steel, in Class-100 clean area, capable of maintaining $\pm 5^\circ\text{C}$ in the 60–70°C temperature range.
- 6.3 Cold vapor atomic fluorescence spectrometer (CVAFS): The CVAFS system used may either be purchased from a supplier, or built in the laboratory from commercially available components.

- 6.3.1 Commercially available CVAFS—Tekran (Toronto, ON) Series 2600 CVAFS, Brooks-Rand (Seattle, WA) Model III CVAFS, Leeman Labs Hydra AF Goldplus CVAFS, or equivalent
- 6.3.2 Custom-built CVAFS (Reference 16.15). Figure 2 shows the schematic diagram. The system consists of the following:
 - 6.3.2.1 Low-pressure 4-W mercury vapor lamp
 - 6.3.2.2 Far UV quartz flow-through fluorescence cell—12 mm x 12 mm x 45 mm, with a 10-mm path length (NSG Cells, or equivalent).
 - 6.3.2.3 UV-visible photomultiplier (PMT)—sensitive to < 230 nm. This PMT is isolated from outside light with a 253.7-nm interference filter (Oriel Corp., Stamford, CT, or equivalent).
 - 6.3.2.4 Photometer and PMT power supply (Oriel Corp. or equivalent), to convert PMT output (nanoamp) to millivolts
 - 6.3.2.5 Black anodized aluminum optical block—holds fluorescence cell, PMT, and light source at perpendicular angles, and provides collimation of incident and fluorescent beams (Frontier Geosciences Inc., Seattle, WA, or equivalent).
 - 6.3.2.6 Flowmeter—with needle valve capable of reproducibly keeping the carrier gas flow rate at 30 mL/min
- 6.4 Hg purging system—Figure 2 shows the schematic diagram for the purging system. The system consists of the following:
 - 6.4.1 Flow meter/needle valve—capable of controlling and measuring gas flow rate to the purge vessel at 350 ± 50 mL/min.
 - 6.4.2 Fluoropolymer fittings—connections between components and columns are made using 6.4-mm OD fluoropolymer tubing and fluoropolymer friction-fit or threaded tubing connectors. Connections between components requiring mobility are made with 3.2-mm OD fluoropolymer tubing because of its greater flexibility.
 - 6.4.3 Acid fume pretrap—10-cm long x 0.9-cm ID fluoropolymer tube containing 2–3 g of reagent grade, nonindicating, 8–14 mesh soda lime chunks, packed between wads of silanized glass wool. This trap is cleaned of Hg by placing on the output of a clean cold vapor generator (bubbler) and purging for 1 h with N₂ at 350 mL/min.
 - 6.4.4 Cold vapor generator (bubbler)—200-mL borosilicate glass (15 cm high x 5.0 cm diameter) with standard taper 24/40 neck, fitted with a sparging stopper having a coarse glass frit that extends to within 0.2 cm of the bubbler bottom (Frontier Geosciences, Inc. or equivalent).
- 6.5 The dual-trap Hg(0) preconcentrating system
 - 6.5.1 Figures 2 and 3 show the dual-trap amalgamation system (Reference 16.5).

- 6.5.2 Gold-coated sand traps—10-cm long x 6.5-mm OD x 4-mm ID quartz tubing. The tube is filled with 3.4 cm of gold-coated 45/60 mesh quartz sand (Frontier Geosciences Inc., Seattle, WA, or equivalent). The ends are plugged with quartz wool.
- 6.5.2.1 Traps are fitted with 6.5-mm ID fluoropolymer friction-fit sleeves for making connection to the system. When traps are not in use, fluoropolymer end plugs are inserted in trap ends to eliminate contamination.
- 6.5.2.2 At least six traps are needed for efficient operation, one as the "analytical" trap, and the others to sequentially collect samples.
- 6.5.3 Heating of gold-coated sand traps—To desorb Hg collected on a trap, heat for 3.0 min to 450–500 °C (a barely visible red glow when the room is darkened) with a coil consisting of 75 cm of 24-gauge Nichrome wire at a potential of 10-14 vac. Potential is applied and finely adjusted with an autotransformer.
- 6.5.4 Timers—The heating interval is controlled by a timer-activated 120-V outlet (Gralab, or equivalent), into which the heating coil autotransformer is plugged. Two timers are required, one each for the "sample" trap and the "analytical" trap.
- 6.5.5 Air blowers—After heating, traps are cooled by blowing air from a small squirrel-cage blower positioned immediately above the trap. Two blowers are required, one each for the "sample" trap and the "analytical" trap.
- 6.6 Recorder—Any multi-range millivolt chart recorder or integrator with a range compatible with the CVAFS is acceptable. By using a two-pen recorder with pen sensitivity offset by a factor of 10, the dynamic range of the system is extended to 10^3 .
- 6.7 Pipettors—All-plastic pneumatic fixed-volume and variable pipettors in the range of 10 μ L to 5.0 mL.
- 6.8 Analytical balance capable of weighing to the nearest 0.01 g

7.0 Reagents and Standards

Note: The quantities of reagents and the preparation procedures in this section are for illustrative purposes. Equivalent performance may be achievable using quantities of reagents and procedures other than those suggested here. The laboratory is responsible for demonstrating equivalent performance.

- 7.1 Reagent water—18-M Ω minimum, ultrapure deionized water starting from a prepurified (distilled, reverse osmosis, etc.) source. Water should be monitored for Hg, especially after ion exchange beds are changed.
- 7.2 Air—It is very important that the laboratory air be low in both particulate and gaseous mercury. Ideally, mercury work should be conducted in a new laboratory with mercury-free paint on the walls. A source of air that is very low in Hg should be brought directly into the Class-100 clean bench air intake. If this is not possible, air coming into the clean bench can be cleaned for mercury by placing a gold-coated cloth prefilter over the intake. Gold-coated cloth filter: Soak 2 m² of cotton gauze in 500 mL of 2% gold chloride solution at pH 7. In a hood, add 100 mL of 30% NH₂OH·HCl solution, and homogenize into the cloth with gloved hands. The material will turn black as colloidal gold is precipitated. Allow the mixture to set for several hours, then rinse

with copious amounts of deionized water. Squeeze-dry the rinsed cloth, and spread flat on newspapers to air-dry. When dry, fold and place over the intake prefilter of the laminar flow hood.

CAUTION: Great care should be taken to avoid contaminating the laboratory with gold dust. This could cause interferences with the analysis if gold becomes incorporated into the samples or equipment. The gilding procedure should be done in a remote laboratory if at all possible.

- 7.3 Hydrochloric acid—trace-metal purified reagent-grade HCl containing less than 5 pg/mL Hg. The HCl should be analyzed for Hg before use.
- 7.4 Hydroxylamine hydrochloride—Dissolve 300 g of $\text{NH}_2\text{OH}\cdot\text{HCl}$ in reagent water and bring to 1.0 L. This solution may be purified by the addition of 1.0 mL of SnCl_2 solution and purging overnight at 500 mL/min with Hg-free N_2 . Flow injection systems may require the use of less SnCl_2 for purification of this solution.
- 7.5 Stannous chloride—Bring 200 g of $\text{SnCl}_2\cdot 2\text{H}_2\text{O}$ and 100 mL concentrated HCl to 1.0 L with reagent water. Purge overnight with mercury-free N_2 at 500 mL/min to remove all traces of Hg. Store tightly capped.
- 7.6 Bromine monochloride (BrCl)—In a fume hood, dissolve 27 g of reagent grade KBr in 2.5 L of low-Hg HCl. Place a clean magnetic stir bar in the bottle and stir for approximately 1 h in the fume hood. Slowly add 38 g reagent grade KBrO_3 to the acid while stirring. When all of the KBrO_3 has been added, the solution color should change from yellow to red to orange. Loosely cap the bottle, and allow to stir another hour before tightening the lid.

WARNING: This process generates copious quantities of free halogens (Cl_2 , Br_2 , BrCl), which are released from the bottle. Add the KBrO_3 slowly in a fume hood!

- 7.7 Stock mercury standard—NIST-certified 10,000-ppm aqueous Hg solution (NIST-3133). This solution is stable at least until the NIST expiration date.
- 7.8 Secondary Hg standard—Add approx 0.5 L of reagent water and 5 mL of BrCl solution (Section 7.6) to a 1.00-L Class A volumetric flask. Add 0.100 mL of the stock mercury standard (Section 7.7) to the flask and dilute to 1.00 L with reagent water. This solution contains 1.00 $\mu\text{g}/\text{mL}$ (1.00 ppm) Hg. Transfer the solution to a fluoropolymer bottle and cap tightly. This solution is considered stable until the NIST expiration date.
- 7.9 Working Hg Standard A—Dilute 1.00 mL of the secondary Hg standard (Section 7.8) to 100 mL in a Class A volumetric flask with reagent water containing 0.5% by volume BrCl solution (Section 7.6). This solution contains 10.0 ng/mL and should be replaced monthly, or longer if extended stability is demonstrated.
- 7.10 Working Hg Standard B—Dilute 0.10 mL of the secondary Hg standard (Section 7.8) to 1000 mL in a Class A volumetric flask with reagent water containing 0.5% by volume BrCl solution (Section 7.6). This solution contains 0.10 ng/mL and should be replaced monthly, or longer if extended stability is demonstrated.
- 7.11 Initial Precision and Recovery (IPR) and Ongoing Precision and Recovery (OPR) solutions—Using the working Hg standard A (Section 7.9), prepare IPR and OPR solutions at a

concentration of 5 ng/L Hg in reagent water. IPR/OPR solutions are prepared using the same amounts of reagents used for preparation of the calibration standards.

- 7.12 Nitrogen—Grade 4.5 (standard laboratory grade) nitrogen that has been further purified by the removal of Hg using a gold-coated sand trap.
- 7.13 Argon—Grade 5.0 (ultra high-purity, GC grade) argon that has been further purified by the removal of Hg using a gold-coated sand trap.

8.0 Sample Collection, Preservation, and Storage

- 8.1 Before samples are collected, consideration should be given to the type of data required (i.e., dissolved or total), so that appropriate preservation and pretreatment steps can be taken. An excess of BrCl should be confirmed either visually (presence of a yellow color) or with starch iodide indicating paper, using a separate sample aliquot, prior to sample processing or direct analysis to ensure the sample has been properly preserved.
- 8.2 Samples are collected into rigorously cleaned fluoropolymer bottles with fluoropolymer or fluoropolymer-lined caps. Glass bottles may be used if Hg is the only target analyte. It is critical that the bottles have tightly sealing caps to avoid diffusion of atmospheric Hg through the threads (Reference 16.4). Polyethylene sample bottles must not be used (Reference 16.15).
- 8.3 Collect samples using guidance provided in the Sampling Method (Reference 16.9). Procedures in the Sampling Method are based on rigorous protocols for collection of samples for mercury (References 16.4 and 16.15).

***NOTE:** Discrete samplers have been found to contaminate samples with Hg at the ng/L level. Therefore, great care should be exercised if this type of sampler is used. It may be necessary for the sampling team to use other means of sample collection if samples are found to be contaminated using the discrete sampler.*

- 8.4 Sample filtration—For dissolved Hg, a sample is filtered through a 0.45- μm capsule filter (Section 6.1.3.1) in a mercury-free clean area prior to preservation. If the sample is filtered, it must be accompanied by a blank that has been filtered under the same conditions. The Sampling Method describes sample filtration procedures.
- 8.5 Preservation—Samples are preserved by adding either 5 mL/L of pretested 12N HCl or 5 mL/L BrCl solution to the sample bottle. If a sample will be used also for the determination of methyl mercury, it should be collected and preserved according to procedures in the method that will be used for determination of methyl mercury (e.g., HCl or H₂SO₄ solution). Preserved samples are stable for up to 90 days of the date of collection.
- 8.5.1 Samples to be analyzed for total or dissolved Hg only may be shipped to the laboratory unpreserved and unrefrigerated if they are collected in fluoropolymer or glass bottles and capped tightly. Samples must be either preserved or analyzed within 48 hours of collection. If a sample is oxidized in the sample bottle, the time to preservation can be extended to 28 days.
- 8.5.2 Samples that are acid-preserved may lose Hg to coagulated organic materials in the water or condensed on the walls (Reference 16.16). The best approach is to add BrCl directly to the sample bottle at least 24 hours before analysis. If other Hg species are to be analyzed, these aliquots must be removed prior to the addition of BrCl. If BrCl

cannot be added directly to the sample bottle, the bottle must be shaken vigorously prior to sub-sampling.

- 8.5.3 Handling of the samples in the laboratory should be undertaken in a mercury-free clean bench, after rinsing the outside of the bottles with reagent water and drying in the clean air hood.

NOTE: Because of the potential for contamination, it is recommended that filtration and preservation of samples be performed in the clean room in the laboratory. However, if circumstances prevent overnight shipment of samples, samples should be filtered and preserved in a designated clean area in the field in accordance with the procedures given in Method 1669 (Reference 16.9). If filtered in the field, samples ideally should be filtered into the sample bottle.

8.6 Storage—Sample bottles should be stored in clean (new) polyethylene bags until sample analysis.

8.7 Sample preservation, storage, and holding time requirements also are given at 40 CFR part 136.3(e) Table II.

9.0 Quality Control

9.1 Each laboratory that uses this Method is required to operate a formal quality assurance program (Reference 16.17). The minimum requirements of this program consist of an initial demonstration of laboratory capability, ongoing analysis of standards and blanks as a test of continued performance, and the analysis of matrix spikes (MS) and matrix spike duplicates (MSD) to assess precision and recovery. Laboratory performance is compared to established performance criteria to determine that the results of analyses meet the performance characteristics of the Method.

9.1.1 The laboratory shall make an initial demonstration of the ability to generate acceptable accuracy and precision. This ability is established as described in Section 9.2.

9.1.2 In recognition of advances that are occurring in analytical technology, the laboratory is permitted certain options to improve results or lower the cost of measurements. These options include automation of the dual-amalgamation system, single-trap amalgamation (Reference 16.18), direct electronic data acquisition, calibration using gas-phase elemental Hg standards, use of the bubbler or flow-injection systems, or changes in the detector (i.e., CVAAS) when less sensitivity is acceptable or desired. Changes in the determinative technique, such as the use of colorimetry, are not allowed. If an analytical technique other than the CVAFS technique specified in this Method is used, that technique must have a specificity for mercury equal to or better than the specificity of the technique in this Method.

9.1.2.1 Each time this Method is modified, the laboratory is required to repeat the procedure in Section 9.2 to demonstrate that an MDL (40 CFR part 136, Appendix B) less than or equal to one-third the regulatory compliance limit or less than or equal to the MDL of this Method (Table 1), whichever is greater, can be achieved. If the change will affect calibration, the instrument must be recalibrated according to Section 10.

Note: If the compliance limit is greater than the concentration of Hg in the OPR/OPR (5 ng/L), the acceptance criteria for blanks and the concentrations of mercury spiked into quality control samples may be increased to support measurements at the compliance limit. For example, if the compliance limit is 12

ng/L (National Toxics Rule, 40 CFR 131.36), the MDL must be less than or equal to 4 ng/L; concentrations of the calibration standards may be 5, 10, 20, 50, and 100 ng/L; concentrations of the IPR/OPR samples may be 10 ng/L; spike concentrations and acceptance criteria for MS/MSD samples would remain as specified in Section 9.3; and an appropriate blank acceptance criterion would be 5 ng/L.

- 9.1.2.2 The laboratory is required to maintain records of modifications made to this Method. These records include the following, at a minimum:
- 9.1.2.2.1 The names, titles, addresses, and telephone numbers of the analyst(s) who performed the analyses and modification, and the quality control officer who witnessed and will verify the analyses and modification
 - 9.1.2.2.2 A narrative stating the reason(s) for the modification(s)
 - 9.1.2.2.3 Results from all quality control (QC) tests demonstrating the performance of the modified method, including the following:
 - (a) Calibration (Section 10)
 - (b) Initial precision and recovery (Section 9.2.2)
 - (c) Analysis of blanks (Section 9.4)
 - (d) Matrix spike/matrix spike duplicate analysis (Section 9.3)
 - (e) Ongoing precision and recovery (Section 9.5)
 - (f) Quality control sample (Section 9.6)
 - (g) Method detection limit (Section 9.2.1)
 - 9.1.2.2.4 Data that will allow an independent reviewer to validate each determination by tracking the instrument output to the final result. These data are to include the following:
 - (a) Sample numbers and other identifiers
 - (b) Processing dates
 - (c) Analysis dates
 - (d) Analysis sequence/run chronology
 - (e) Sample weight or volume
 - (f) Copies of logbooks, chart recorder, or other raw data output
 - (g) Calculations linking raw data to the results reported
- 9.1.3 Analyses of MS and MSD samples are required to demonstrate the accuracy and precision and to monitor matrix interferences. Section 9.3 describes the procedure and QC criteria for spiking.
- 9.1.4 Analyses of blanks are required to demonstrate acceptable levels of contamination. Section 9.4 describes the procedures and criteria for analyzing blanks.
- 9.1.5 The laboratory shall, on an ongoing basis, demonstrate through analysis of the ongoing precision and recovery (OPR) sample and the quality control sample (QCS) that the system is in control. Sections 9.5 and 9.6 describe these procedures, respectively.
- 9.1.6 The laboratory shall maintain records to define the quality of the data that are generated. Sections 9.3.7 and 9.5.3 describe the development of accuracy statements.
- 9.1.7 Quality of the analyses is controlled by an analytical batch. An analytical batch is a set of samples oxidized with the same batch of reagents, and analyzed during the same 12-hour shift. A batch may be from 1 to as many as 20 samples. Each batch must be accompanied by 3 system blanks (Section 9.4.2 for the flow-injection system), a

minimum of 3 bubbler blanks (Section 9.4.1 for the bubbler system), 1 OPR sample at the beginning and end of the batch (Section 9.5), a QCS (Section 9.6), and at least 3 method blanks (Section 9.4.4). In addition, there must be 1 MS and 1 MSD sample for every 10 samples (a frequency of 10%). A typical analytical sequence would be:

- (a) Three system blanks (Section 9.4.2) or a minimum of 3 bubbler blanks (Section 9.4.1)
- (b) A minimum of five, non-zero calibration standards (Section 10.2.2.1)
- (c) On-going precision and recovery (Section 9.5)
- (d) Quality control sample (Section 9.6)
- (e) Method blank (Section 9.4.4)
- (f) Seven samples
- (g) Method blank (Section 9.4.4)
- (h) Three samples
- (i) Matrix spike (Section 9.3)
- (j) Matrix spike duplicate (Section 9.3)
- (k) Four samples
- (l) Method blank (Section 9.4.4)
- (m) Six samples
- (n) Matrix spike (Section 9.3)
- (o) Matrix spike duplicate (Section 9.3)
- (p) Ongoing precision and recovery (Section 9.5)

The above sequence includes calibration. If system performance is verified at the end of the sequence using the OPR, analysis of samples and blanks may proceed without recalibration (i.e., the analytical sequence would be entered at Step (d) above), unless more than 12 hours has elapsed since verification of system performance. If more than 12 hours has elapsed, the sequence would be initiated at Step (c) above.

9.2 Initial demonstration of laboratory capability

9.2.1 Method detection limit—To establish the ability to detect Hg, the laboratory shall achieve an MDL that is less than or equal to the MDL listed in Section 1.5 or one-third the regulatory compliance limit, whichever is greater. The MDL shall be determined according to the procedure at 40 CFR 136, Appendix B using the apparatus, reagents, and standards that will be used in the practice of this Method. This MDL shall be used for determination of laboratory capability only, and should be determined when a new operator begins work or whenever, in the judgment of the laboratory, a change in instrument hardware or operating conditions would dictate reevaluation of capability.

9.2.2 Initial precision and recovery (IPR)—To establish the ability to generate acceptable precision and recovery, the laboratory shall perform the following operations:

9.2.2.1 Analyze four replicates of the IPR solution (5 ng/L, Section 7.11) according to the procedure beginning in Section 11.

9.2.2.2 Using the results of the set of four analyses, compute the average percent recovery (\bar{X}), and the standard deviation of the percent recovery (s) for Hg.

9.2.2.3 Compare s and \bar{X} with the corresponding limits for initial precision and recovery in Table 2. If s and \bar{X} meet the acceptance criteria, system performance is acceptable and analysis of samples may begin. If, however, s exceeds the

precision limit or X falls outside the acceptance range, system performance is unacceptable. Correct the problem and repeat the test (Section 9.2.2.1).

9.3 Matrix spike (MS) and matrix spike duplicate (MSD)—To assess the performance of the Method on a given sample matrix, the laboratory must spike, in duplicate, a minimum of 10% (1 sample in 10) from a given sampling site or, if for compliance monitoring, from a given discharge. Therefore, an analytical batch of 20 samples would require two pairs of MS/MSD samples (four spiked samples total).

9.3.1 The concentration of the spike in the sample shall be determined as follows:

9.3.1.1 If, as in compliance monitoring, the concentration of Hg in the sample is being checked against a regulatory compliance limit, the spiking level shall be at that limit or at 1–5 times the background concentration of the sample (as determined in Section 9.3.2), whichever is greater.

9.3.1.2 If the concentration of Hg in a sample is not being checked against a limit, the spike shall be at 1–5 times the background concentration or at 1-5 times the ML in Table 1, whichever is greater.

9.3.2 To determine the background concentration (B), analyze one sample aliquot from each set of 10 samples from each site or discharge according to the procedure in Section 11. If the expected background concentration is known from previous experience or other knowledge, the spiking level may be established *a priori*.

9.3.2.1 If necessary, prepare a standard solution to produce an appropriate level in the sample (Section 9.3.1).

9.3.2.2 Spike two additional sample aliquots with identical amounts of the spiking solution and analyze these aliquots as described in Section 11.1.2 to determine the concentration after spiking (A).

9.3.3 Calculate the percent recovery (R) in each aliquot using the following equation:

$$\% R = 100 \frac{(A-B)}{T}$$

where:

A = Measured concentration of analyte after spiking

B = Measured concentration of analyte before spiking

T = True concentration of the spike

9.3.4 Compare percent recovery (R) with the QC acceptance criteria in Table 2.

9.3.4.1 If results of the MS/MSD are similar and fail the acceptance criteria, and recovery for the OPR standard (Section 9.5) for the analytical batch is within the acceptance criteria in Table 2, an interference is present and the results may not be reported or otherwise used for permitting or regulatory compliance purposes. If the interference can be attributed to sampling, the site or discharge should be resampled. If the interference can be attributed to a method deficiency, the laboratory must modify the method, repeat the test required in Section 9.1.2, and repeat analysis of the sample and MS/MSD. However, during the development

of Method 1631, very few interferences have been noted in the determination of Hg using this Method. (See Section 4.4 for information on interferences.)

9.3.4.2 If the results of both the spike and the OPR test fall outside the acceptance criteria, the analytical system is judged to be not in control, and the results may not be reported or used for permitting or regulatory compliance purposes. The laboratory must identify and correct the problem and reanalyze all samples in the sample batch.

9.3.5 Relative percent difference (RPD)—Compute the RPD between the MS and MSD results according to the following equation using the concentrations found in the MS and MSD. Do not use the recoveries calculated in Section 9.3.3 for this calculation because the RPD is inflated when the background concentration is near the spike concentration.

$$RPD = 200 \times \frac{(|D1 - D2|)}{(D1 + D2)}$$

Where:

D1 = concentration of Hg in the MS sample

D2 = concentration of Hg in the MSD sample

9.3.6 The RPD for the MS/MSD pair must not exceed the acceptance criterion in Table 2. If the criterion is not met, the system is judged to be out of control. The problem must be identified and corrected, and the MS/MSD and corresponding samples reanalyzed.

9.3.7 As part of the QC program for the laboratory, method precision and recovery for samples should be assessed and records maintained. After analyzing five samples in which the recovery passes the test in Section 9.3.4, compute the average percent recovery (R_a) and the standard deviation of the percent recovery (s_r). Express the accuracy assessment as a percent recovery interval from $R_a - 2s_r$ to $R_a + 2s_r$. For example, if $R_a = 90\%$ and $s_r = 10\%$ for five analyses, the accuracy interval is expressed as 70–110%. Update the accuracy assessment regularly (e.g., after every five to ten new accuracy measurements).

9.4 Blanks—Blanks are critical to the reliable determination of Hg at low levels. The sections below give the minimum requirements for analysis of blanks. Analysis of additional blanks is recommended as necessary to pinpoint sources of contamination in, and external to, the laboratory.

9.4.1 Bubbler blanks—Bubbler blanks are analyzed to demonstrate that bubbler systems are free from contamination at levels that could affect data quality. At least three bubbler blanks must be run during calibration and with each analytical batch.

9.4.1.1 To analyze a bubbler blank, place a clean gold trap on the bubbler. Purge and analyze previously purged water using the procedure in Section 11, and determine the amount of Hg remaining in the system.

9.4.1.2 If the bubbler blank is found to contain more than 50 pg Hg, the system is out of control. The problem must be investigated and remedied, and the samples run on that bubbler must be reanalyzed. If the blanks from other bubblers contain less than 50 pg Hg, the data associated with those bubblers remain valid, provided that all other criteria in Section 9 also are met.

- 9.4.1.3 The mean result for all bubbler blanks (from bubblers passing the specification in Section 9.4.1.2) must be < 25 pg (0.25 ng/L) Hg with a standard deviation (n-1) of < 10 pg (0.10 ng/L). If the mean is < 25 pg, the average peak area or height is subtracted from all raw data before results are calculated (Section 12.2).
- 9.4.1.4 If Hg in the bubbler blank exceeds the acceptance criteria in Section 9.4.1.3, the system is out of control. The problem must be resolved and the system recalibrated. Usually, the bubbler blank is too high for one of the following reasons:
- Bubblers need rigorous cleaning;
 - Soda-lime is contaminated; or
 - Carrier gas is contaminated.
- 9.4.2 System blanks— System blanks are analyzed to demonstrate that flow injection systems are free from contamination at levels that could affect data quality. Three system blanks must be run during calibration and with each analytical batch.
- 9.4.2.1 To analyze a system blank, analyze reagent water containing the same amount of reagents used to prepare the calibration standards.
- 9.4.2.2 If a system blank is found to contain ≥ 0.50 ng/L Hg, the system is out of control. The problem must be investigated and remedied, and the system recalibrated. If the blanks contain < 0.50 ng/L Hg, the data associated with the blanks remain valid, provided that all other criteria in Section 9 also are met.
- 9.4.2.3 The mean result for the three system blanks must be < 0.5 ng/L Hg with a standard deviation (n-1) < 0.1 ng/L. If the mean exceeds these criteria, the system is out of control, and the problem must be resolved and the system recalibrated. If the mean is < 0.5 ng/L, the average peak height or area is subtracted from all raw data before results are calculated (Section 12.3).
- 9.4.3 Reagent blanks— Reagent blanks are used to demonstrate that the reagents used to prepare samples for Hg analyses are free from contamination. The Hg concentration in reagent blanks is determined by analyzing the reagent solutions using either the bubbler or flow-injection system. For the bubbler system, reagent may be added directly to previously purged water in the bubbler.
- 9.4.3.1 Reagent blanks are required when the batch of reagents (bromine monochloride plus hydroxylamine hydrochloride) are prepared. The amount of Hg in a reagent blank containing 0.5% (v/v) BrCl solution (Section 7.6) and 0.2% (v/v) hydroxylamine hydrochloride solution (Section 7.4) must be < 20 pg (0.2 ng/L).
- 9.4.3.2 The presence of more than 20 pg (0.2 ng/L) of Hg indicates a problem with the reagent solution. The purging of certain reagent solutions, such as SnCl₂ or NH₂OH, with mercury-free nitrogen or argon can reduce Hg to acceptable levels. Because BrCl cannot be purified, a new batch must be prepared and tested if the BrCl is contaminated.
- 9.4.4 Method blanks— Method blanks are used to demonstrate that the analytical system is free from contamination that could otherwise compromise sample results. Method blanks are prepared and analyzed using sample containers, labware, reagents, and analytical procedures identical to those used to prepare and analyze the samples.

- 9.4.4.1 A minimum of three method blanks per analytical batch are required for both the bubbler and flow-injection systems.
- 9.4.4.2 If the result for any method blank containing the nominal amount of reagent used to prepare a sample (Section 11.1.1) is found to contain ≥ 0.50 ng/L (50 pg) Hg, the system is out of control. Mercury in the analytical system must be reduced until a method blank is free from contamination at the 0.50 ng/L level. Samples associated with a contaminated method blank must be reanalyzed.
- 9.4.4.3 Because method blanks are analyzed using procedures identical to those used to analyze samples, any sample requiring an increased amount of reagent must be accompanied by at least one method blank that includes an identical amount of reagent.
- 9.4.5 Field blanks—Field blanks are used to demonstrate that samples have not been contaminated by the sample collection and transport activities.
 - 9.4.5.1 Analyze the field blank(s) shipped with each set of samples (samples collected from the same site at the same time, to a maximum of 10 samples). Analyze the blank immediately before analyzing the samples in the batch.
 - 9.4.5.2 If Hg or any potentially interfering substance is found in the field blank at a concentration equal to or greater than the ML (Table 1), or greater than one-fifth the level in the associated sample, whichever is greater, results for associated samples may be the result of contamination and may not be reported or otherwise used for regulatory compliance purposes.
 - 9.4.5.3 Alternatively, if sufficient multiple field blanks (a minimum of three) are collected, and the average concentration (of the multiple field blanks) plus two standard deviations is equal to or greater than the regulatory compliance limit or equal to or greater than one-half of the level in the associated sample, results for associated samples may be the result of contamination and may not be reported or otherwise used for regulatory compliance purposes.
 - 9.4.5.4 If contamination of the field blanks and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified and corrective measures taken before the next sampling event.
- 9.4.6 Equipment blanks—Before any sampling equipment is used at a given site, the laboratory or cleaning facility is required to generate equipment blanks on all sampling equipment that will be used to demonstrate that the sampling equipment is free from contamination.
 - 9.4.6.1 Equipment blanks are generated in the laboratory or at the equipment cleaning facility by processing reagent water through the sampling devices using the same procedures that are used in the field (see Sampling Method). Therefore, the "clean hands/dirty hands" technique used during field sampling should be followed when preparing equipment blanks at the laboratory or cleaning facility for low level mercury measurements. If grab samples are to be collected using any ancillary equipment, e.g., an extension pole or a dipper, an equipment blank

is generated by submersing this equipment into the reagent water and analyzing the resulting reagent water collected.

- 9.4.6.2 The equipment blank must be analyzed using the procedures in this Method. If mercury or any potentially interfering substance is detected in the blank at or above the level specified for the field blank (Section 9.4.5), the source of contamination or interference must be identified, and the problem corrected. The equipment must be demonstrated to be free from mercury and interferences before the equipment may be used in the field.
- 9.4.7 Bottle blanks— Bottles must be subjected to conditions of use to verify the effectiveness of the cleaning procedures. A representative set of sample bottles (Section 6.1.2) should be filled with reagent water acidified to pH <2 and allowed to stand for a minimum of 24 h. At least 5% of the bottles from a given lot should be tested, and the time that the bottles are allowed to stand should be as close as possible to the actual time that the sample will be in contact with the bottle. After standing, the water must be analyzed for any signs of contamination. If a bottle shows contamination at or above the level specified for the field blank (Section 9.4.5), the problem must be identified, the cleaning procedures corrected or cleaning solutions changed, and all affected bottles re-cleaned.
- 9.5 Ongoing precision and recovery (OPR)—To demonstrate that the analytical system is within the performance criteria of this Method and that acceptable precision and recovery is being maintained within each analytical batch, the laboratory shall perform the following operations:
- 9.5.1 Analyze the OPR solution (5 ng/L, Section 7.11) prior to the analysis of each analytical batch according to the procedure beginning in Section 11. An OPR also must be analyzed at the end of an analytical sequence or at the end of each 12-hour shift.
- 9.5.2 Compare the recovery with the limits for ongoing precision and recovery in Table 2. If the recovery is in the range specified, the analytical system is in control and analysis of samples and blanks may proceed. If, however, the concentration is not in the specified range, the analytical process is not in control. Correct the problem and repeat the ongoing precision and recovery test. All reported results must be associated with an OPR that meets the Table 2 performance criteria at the beginning and end of each batch.
- 9.5.3 The laboratory should add results that pass the specification in Section 9.5.2 to IPR and previous OPR data and update QC charts to form a graphic representation of continued laboratory performance. The laboratory also should develop a statement of laboratory data quality by calculating the average percent recovery (R_a) and the standard deviation of the percent recovery (s_r). Express the accuracy as a recovery interval from $R_a - 2s_r$ to $R_a + 2s_r$. For example, if $R_a = 95\%$ and $s_r = 5\%$, the accuracy is 85–105%.
- 9.6 Quality control sample (QCS) – The laboratory must obtain a QCS from a source different from the Hg used to produce the standards used routinely in this Method (Sections 7.7–7.10). The QCS should be analyzed as an independent check of system performance.
- 9.7 Depending on specific program requirements, the laboratory may be required to analyze field duplicates and field spikes collected to assess the precision and accuracy of the sampling, sample transportation, and storage techniques. The relative percent difference (RPD) between field duplicates should be less than 20%. If the RPD of the field duplicates exceeds 20%, the laboratory should communicate this to the sampling team so that the source of error can be identified and corrective measures taken before the next sampling event.

10.0 Calibration and Standardization

- 10.1 Calibration and standardization— Separate calibration procedures are provided for a bubbler system (Section 10.2) and flow-injection system (Section 10.3). Both systems are calibrated using standards traceable to NIST Standard Reference Materials. If system performance is verified at the end of an analytical batch using the OPR, analysis of samples and blanks may proceed without recalibration, unless more than 12 hours has elapsed since verification of system performance.
- 10.2 Bubbler system calibration
- 10.2.1 Establish the operating conditions necessary to purge Hg from the bubbler and to desorb Hg from the traps in a sharp peak. Further details for operation of the purge-and-trap, desorption, and analysis systems are given in Sections 11.2.1 and 11.2.2.
- 10.2.2 The calibration must contain a minimum of five non-zero points and the results of analysis of three bubbler blanks. The lowest calibration point must be at the Minimum Level (ML).

NOTE: The purge efficiency of the bubbler system is 100% and is independent of volume at the volumes used in this Method. Calibration of this system is typically performed using units of mass. For purposes of working in concentration, the volume is assumed to be 100 mL.

- 10.2.2.1 Standards are analyzed by the addition of aliquots of Hg working standard A (Section 7.9) and Hg working standard B (Section 7.10) directly into the bubblers. Add 0.50 mL of working standard B and 0.5 mL SnCl₂ to the bubbler. Swirl to produce a standard containing 50 pg of Hg (0.5 ng/L). Purge under the optimum operating conditions (Section 10.2.1). Sequentially follow with the addition of aliquots of 0.05, 0.25, 0.50 and 1.0 mL of working standard A to produce standards of 500, 2500, 5000, and 10,000 pg Hg (5.0, 25.0, 50.0 and 100.0 ng/L).

NOTE: If calibration to the higher levels results in carryover (Section 4.3.8.1), calibrate the system across a narrower range (Section 10.4)

- 10.2.2.2 Analyze the standards beginning with the lowest concentration and proceeding to the highest. Tabulate the height or area for each peak.
- 10.2.2.3 Prepare and analyze a minimum of 3 bubbler blanks. If multiple bubblers are used, there must be 1 bubbler blank per bubbler (to a maximum of 4 bubblers). Calculate the mean peak area or height for the bubbler blanks.
- 10.2.2.4 For each calibration point, subtract the mean peak height or area of the bubbler blanks from the peak height or area for each standard. Calculate the calibration factor (CF_x) for Hg in each of the five standards using the mean bubbler-blank-subtracted peak height or area and the following equation:

$$CF_x = \frac{(A_x) - (\bar{A}_{BB})}{(C_x)}$$

Where:

A_x = peak height or area for Hg in standard

\bar{A}_{BB} = mean peak height or area for Hg in bubbler blank

C_x = mass in standard analyzed (ng)

- 10.2.2.5 Calculate the mean calibration factor (CF_m), the standard deviation of the calibration factor (SD; n-1), and the relative standard deviation (RSD) of the calibration factor, where $RSD = 100 \times SD/CF_m$.
- 10.2.2.6 If $RSD \leq 15\%$, calculate the recovery for the lowest standard using CF_m . If the $RSD \leq 15\%$ and the recovery of the lowest standard is in the range of 75-125%, the calibration is acceptable and CF_m may be used to calculate the concentration of Hg in samples. If $RSD > 15\%$ or if the recovery of the lowest standard is not in the range of 75-125%, recalibrate the analytical system and repeat the test.
- 10.2.2.7 Calculate the concentration of Hg in the bubbler blanks (Section 10.2.2.1) using CF_m . The bubbler blanks must meet the criteria in Section 9.4.1; otherwise, mercury in the system must be reduced and the calibration repeated until the bubbler blanks meet the criteria.

10.3 Flow-injection system calibration

- 10.3.1 Establish the operating conditions necessary to purge Hg from the gas-liquid separator and dryer tube and desorb Hg from the traps in a sharp peak. Further details for operating the analytical system are given in Section 11.2.1.
- 10.3.2 The calibration must contain a minimum of 5 non-zero points and the results of analysis of 3 system blanks. The lowest calibration point must be at the minimum level (ML).
- 10.3.2.1 Place 25-30 mL of reagent water and 250 μ L of concentrated BrCl solution (Section 7.6) in each of 5 calibrated 50-mL autosampler vials. Prepare the 0.5 ng/L calibration standard by adding 250 μ L of working standard B (Section 7.10) to the vial. Dilute to the mark with reagent water. Sequentially follow with the addition of aliquots of 25, 125, 250 and 500 μ L of working standard A (Section 7.9) to produce standards of 5.0, 25.0, 50.0 and 100.0 ng/L, respectively. Cap the vials and invert once to mix.
- 10.3.2.2 Immediately prior to analysis, remove the caps and add 125 μ L of NH_2OH solution (Section 7.4). Re-cap, invert once to mix, and allow to stand until the yellow color disappears. Remove all caps and place vials into the analysis rack.
- 10.3.2.3 Analyze the standards beginning with the lowest concentration and proceeding to the highest. Tabulate the height or area for the Hg peak.
- 10.3.2.4 Prepare and analyze a minimum of 3 system blanks and tabulate the peak heights or areas. Calculate the mean peak area or height for the system blanks.
- 10.3.2.5 For each calibration point, subtract the mean peak height or area of the system blanks (Section 9.4.2) from the peak height or area for each standard. Calculate

the calibration factor (CF_x) for Hg in each of the five standards using the mean reagent-blank-subtracted peak height or area and the following equation:

$$CF_x = \frac{(A_x) - (\bar{A}_{SB})}{(C_x)}$$

Where:

- A_x = peak height or area for Hg in standard
 \bar{A}_{SB} = mean peak height or area for Hg in calibration blanks
 C_x = concentration of standard analyzed (ng/L)

- 10.3.2.6 Calculate the mean calibration factor (CF_m), the standard deviation of the calibration factor (SD; n-1), and the relative standard deviation (RSD) of the calibration factor, where $RSD = 100 \times SD/CF_m$.
- 10.3.2.7 If $RSD \leq 15\%$, calculate the recovery for the lowest standard (0.5 ng/L) using CF_m . If the $RSD \leq 15\%$ and the recovery of the lowest standard is in the range of 75-125%, the calibration is acceptable and CF_m may be used to calculate the concentration of Hg in samples, blanks, and OPRs. If $RSD > 15\%$ or if the recovery of the lowest standard is not in the range of 75-125%, recalibrate the analytical system and repeat the test.
- 10.3.2.8 Calculate the concentration of Hg in the system blanks (Section 9.4.2) using CF_m . The system blanks must meet the criteria in Section 9.4.2; otherwise, mercury in the system must be reduced and the calibration repeated until the system blanks meet the criteria.
- 10.4 Calibration to a range other than 0.5 to 100 ng/L—This Method may be calibrated to a range other than 0.5 to 100 ng/L, provided that the following requirements are met:
- There must be a minimum of five non-zero calibration points.
 - The difference between successive calibration points must be no greater than a factor of 10 and no less than a factor of 2 and should be approximately evenly spaced on a logarithmic scale over the calibration range.
 - The relative standard deviation (RSD) of the calibration factors for all calibration points must be less than 15%.
 - The calibration factor for any calibration point at a concentration greater than 100 ng/L must be within $\pm 15\%$ of the average calibration factor for the points at or below 100 ng/L.
 - The calibration factor for any point < 0.5 ng/L must be within 25% of the average calibration factor for all points.
 - If calibration is to a higher range and this Method is used for regulatory compliance, the ML must be less than one-third the regulatory compliance limit

11.0 Procedure

NOTE: The following procedures for analysis of samples are provided as guidelines. Laboratories may find it necessary to optimize the procedures, such as drying time or potential applied to the Nichrome wires, for the laboratory's specific instrument set-up.

11.1 Sample Preparation

- 11.1.1 Pour a 100-mL aliquot from a thoroughly shaken, acidified sample, into a 125-mL fluoropolymer bottle. If BrCl was not added as a preservative (Section 8.5), add the amount of BrCl solution (Section 7.6) given below, cap the bottle, and digest at room temperature for a 12 h minimum.
- 11.1.1.1 For clear water and filtered samples, add 0.5 mL of BrCl; for brown water and turbid samples, add 1.0 mL of BrCl. If the yellow color disappears because of consumption by organic matter or sulfides, more BrCl should be added until a permanent (12-h) yellow color is obtained.
- 11.1.1.2 Some highly organic matrices, such as sewage effluent, will require high levels of BrCl (e.g., 5 mL/100 mL of sample) and longer oxidation times, or elevated temperatures (e.g., place sealed bottles in oven at 50 °C for 6 h). The oxidation must be continued until it is complete. Complete oxidation can be determined by either observation of a permanent yellow color remaining in the sample or the use of starch iodide indicating paper to test for residual free oxidizer. The sample also may be diluted to reduce the amount of BrCl required, provided that the resulting level of mercury is sufficient for reliable determination.
- 11.1.2 Matrix spikes and matrix spike duplicates—For every 10 or fewer samples, pour 2 additional 100-mL aliquots from a selected sample (see Section 9.3), spike at the level specified in Section 9.3, and process in the same manner as the samples. There must be a minimum of 2 MS/MSD pairs for each analytical batch of 20 samples.

11.2 Hg reduction and purging—Separate procedures are provided for the bubbler system (Section 11.2.1) and flow-injection (Section 11.2.2).

11.2.1 Hg reduction and purging for the bubbler system

- 11.2.1.1 Add 0.2-0.25 mL of NH_2OH solution to the BrCl-oxidized sample in the 125-mL sample bottle. Cap the bottle and swirl the sample. The yellow color will disappear, indicating the destruction of the BrCl. Allow the sample to react for 5 min with periodic swirling to be sure that no traces of halogens remain.

NOTE: *Purging of free halogens onto the gold trap will result in damage to the trap and low or irreproducible results.*

- 11.2.1.2 Connect a fresh trap to the bubbler, pour the reduced sample into the bubbler, add 0.5 mL of SnCl_2 solution, and purge the sample onto a gold trap with N_2 at 350 ± 50 mL/min for 20 min.
- 11.2.1.3 When analyzing Hg samples, the recovery is quantitative, and organic interferences are destroyed. Thus, standards, bubbler blanks, and small amounts of high-level samples may be run directly in previously purged water. After very high samples (Section 4.3.8.1), a small degree of carryover (<0.01%) may occur. Bubblers that contain such samples must be demonstrated to be clean prior to proceeding with low level samples. Samples run immediately following a sample that has been determined to result in carryover must be reanalyzed using a bubbler that is demonstrated to be clean as per Section 4.3.8.1.

11.2.2 Hg reduction and purging for the flow-injection system

- 11.2.2.1 Add 0.2-0.25 mL of NH_2OH solution (Section 7.4) to the BrCl -oxidized sample in the 125-mL sample bottle or in the autosampler tube (the amount of NH_2OH required will be approximately 30 percent of the BrCl volume). Cap the bottle and swirl the sample. The yellow color will disappear, indicating the destruction of the BrCl . Allow the sample to react for 5 minutes with periodic swirling to be sure that no traces of halogens remain.

NOTE: *Purging of free halogens onto the gold trap will result in damage to the trap and low or irreproducible results.*

- 11.2.2.2 Pour the sample solution into an autosampler vial and place the vial in the rack.
- 11.2.2.3 Carryover may occur after analysis of a sample containing a high level of mercury. Samples run immediately following a sample that has been determined to result in carryover (Section 4.3.8.1) must be reanalyzed using a system demonstrated to be clean as per Section 4.3.8.1.

11.3 Desorption of Hg from the gold trap

- 11.3.1 Remove the sample trap from the bubbler, place the Nichrome wire coil around the trap and connect the trap into the analyzer train between the incoming Hg-free argon and the second gold-coated (analytical) sand trap (Figure 2).
- 11.3.2 Pass argon through the sample and analytical traps at a flow rate of approximately 30 mL/min for approximately 2 min to drive off condensed water vapor.
- 11.3.3 Apply power to the coil around the sample trap for 3 minutes to thermally desorb the Hg (as $\text{Hg}(0)$) from the sample trap onto the analytical trap.
- 11.3.4 After the 3-min desorption time, turn off the power to the Nichrome coil, and cool the sample trap using the cooling fan.
- 11.3.5 Turn on the chart recorder or other data acquisition device to start data collection, and apply power to the Nichrome wire coil around the analytical trap. Heat the analytical trap for 3 min (1 min beyond the point at which the peak returns to baseline).
- 11.3.6 Stop data collection, turn off the power to the Nichrome coil, and cool the analytical trap to room temperature using the cooling fan.
- 11.3.7 Place the next sample trap in line and proceed with analysis of the next sample.

NOTE: *Do not heat a sample trap while the analytical trap is still warm; otherwise, the analyte may be lost by passing through the analytical trap.*

11.4 Peaks generated using this technique should be very sharp and almost symmetrical. Mercury elutes at approximately 1 minute and has a width at half-height of about 5 seconds.

- 11.4.1 Broad or asymmetrical peaks indicate a problem with the desorption train, such as improper gas flow rate, water vapor on the trap(s), or an analytical trap damaged by chemical fumes or overheating.

- 11.4.2 Damage to an analytical trap is also indicated by a sharp peak, followed by a small, broad peak.
- 11.4.3 If the analytical trap has been damaged, the trap and the fluoropolymer tubing downstream from it should be discarded because of the possibility of gold migration onto downstream surfaces.
- 11.4.4 Gold-coated sand traps should be tracked by unique identifiers so that any trap producing poor results can be quickly recognized and discarded.

12.0 Data Analysis and Calculations

12.1 Separate procedures are provided for calculation of sample results using the bubbler system (Section 12.2) and the flow-injection system (Section 12.3), and for method blanks (Section 12.4).

12.2 Calculations for the bubbler system

- 12.2.1 Calculate the mean peak height or area for Hg in the bubbler blanks measured during system calibration or with the analytical batch (A_{BB} ; $n = 3$ minimum).
- 12.2.2 Calculate the concentration of Hg in ng/L (parts-per-trillion; ppt) in each sample according to the following equation:

$$[\text{Hg}] \text{ (ng/L)} = \frac{A_s - \bar{A}_{BB}}{CF_m \times V}$$

where:

A_s = peak height (or area) for Hg in sample

\bar{A}_{BB} = peak height (or area) for Hg in bubbler blank

CF_m = mean calibration factor (Section 10.2.2.5)

V = Volume of sample (L)

12.3 Calculations for the flow-injection system

- 12.3.1 Calculate the mean peak height or area for Hg in the system blanks measured during system calibration or with each analytical batch (A_{SB} ; $n = 3$)
- 12.3.2 Calculate the concentration of Hg in ng/L in each sample according to the following equation:

$$[\text{Hg}] \text{ (ng/L)} = \frac{(A_s - \bar{A}_{SB})}{CF_m} \times \frac{V_{std}}{V_{sample}}$$

where:

A_s = peak height (or area) for Hg in sample

\bar{A}_{SB} = mean peak height (or area) for Hg in system blanks

CF_m = mean calibration factor (Section 10.3.2.6)

V_{std} = volume (mL) used for standards - volume (mL) reagent used in standards

V_{sample} = volume (mL) of sample - volume (mL) reagent used in sample

12.4 Calculations for concentration of Hg in method blanks, field blanks, and reagent blanks.

- 12.4.1 Calculate the concentration of Hg in the method blanks (C_{MB}), field blanks (C_{FB}), or reagent blanks (C_{RB}) in ng/L, using the equation in Section 12.2.2 (if bubbler system is used) or Section 12.3.2 (if flow injection system is used) and substituting the peak height or area resulting from the method blank, field blank, or reagent blank for A_s .
- 12.4.2 Determine the mean concentration of Hg in the method blanks associated with the analytical batch (a minimum of three). If a sample requires additional reagent(s) (e.g., BrCl), a corresponding method blank containing an identical amount of reagent must be analyzed (Section 9.4.4.3). The concentration of Hg in the corresponding method blank may be subtracted from the concentration of Hg in the sample per Section 12.5.2.

12.5 Reporting

- 12.5.1 Report results for Hg at or above the ML, in ng/L, to three significant figures. Report results for Hg in samples below the ML as <0.5 ng/L, or as required by the regulatory authority or in the permit. Report results for Hg in reagent blanks and field blanks at or above the ML, in ng/L, to three significant figures. Report results for Hg in reagent blanks, method blanks, or field blanks below the ML but at or above the MDL to two significant figures. Report results for Hg not detected in reagent blanks, method blanks, or field blanks as <0.2 ng/L, or as required by the regulatory authority or in the permit.
- 12.5.2 Report results for Hg in samples, method blanks and field blanks separately. In addition to reporting results for the samples and blank(s) separately, the concentration of Hg in the method blanks or field blanks associated with the sample may be subtracted from the results for that sample, or must be subtracted if requested or required by a regulatory authority or in a permit.
- 12.5.3 Results from tests performed with an analytical system that is not in control must not be reported or otherwise used for permitting or regulatory compliance purposes, but do not relieve a discharger or permittee of reporting timely results.

13.0 Method Performance

- 13.1 This Method was tested in 12 laboratories using reagent water, freshwater, marine water and effluent (Reference 16.19). The quality control acceptance criteria listed in Table 2 were verified by data gathered in the interlaboratory study, and the method detection limit (MDL) given in Section 1.5 was verified in all 12 laboratories. In addition, the techniques in this Method have been compared with other techniques for low-level mercury determination in water in a variety of studies, including ICES-5 (Reference 16.20) and the International Mercury Speciation Intercomparison Exercise (Reference 16.21).
- 13.2 Precision and recovery data for reagent water, freshwater, marine water, and secondary effluent are given in Table 3.

14.0 Pollution Prevention

- 14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity or toxicity of waste at the point of generation. Many opportunities for pollution prevention exist in laboratory operation. EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address waste generation. When it is not feasible to reduce wastes at the source, the Agency recommends recycling as the next best option. The acids used in this Method should be reused as practicable by purifying by electrochemical techniques. The only other chemicals used in this Method are the neat materials used in preparing standards. These standards are used in extremely small amounts and pose little threat to the environment when managed properly. Standards should be prepared in volumes consistent with laboratory use to minimize the disposal of excess volumes of expired standards.
- 14.2 For information about pollution prevention that may be applied to laboratories and research institutions, consult *Less is Better: Laboratory Chemical Management for Waste Reduction*, available from the American Chemical Society's Department of Governmental Relations and Science Policy, 1155 16th Street NW, Washington DC 20036, 202/872-4477.

15.0 Waste Management

- 15.1 The laboratory is responsible for complying with all Federal, State, and local regulations governing waste management, particularly hazardous waste identification rules and land disposal restrictions, and for protecting the air, water, and land by minimizing and controlling all releases from fume hoods and bench operations. Compliance with all sewage discharge permits and regulations is also required. An overview of requirements can be found in *Environmental Management Guide for Small Laboratories* (EPA 233-B-98-001).
- 15.2 Acids, samples at pH <2, and BrCl solutions must be neutralized before being disposed of, or must be handled as hazardous waste.
- 15.3 For further information on waste management, consult *The Waste Management Manual for Laboratory Personnel* and *Less is Better: Laboratory Chemical Management for Waste Reduction*, both available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th Street NW, Washington, DC 20036.

17.0 Glossary

The definitions and purposes below are specific to this Method, but have been conformed to common usage as much as possible.

- 17.1 **Ambient Water**—Waters in the natural environment (e.g., rivers, lakes, streams, and other receiving waters), as opposed to effluent discharges.
- 17.2 **Analytical Batch**—A batch of up to 20 samples that are oxidized with the same batch of reagents and analyzed during the same 12-hour shift. Each analytical batch must also include at least three bubbler blanks, an OPR, and a QCS. In addition, MS/MSD samples must be prepared at a frequency of 10% per analytical batch (one MS/MSD for every 10 samples).
- 17.3 **Bottle Blank**—The bottle blank is used to demonstrate that the bottle is free from contamination prior to use. Reagent water known to be free of mercury at the MDL of this Method is added to a bottle, acidified to pH <2 with BrCl or HCl, and allowed to stand for a minimum of 24 hours. The time that the bottle is allowed to stand should be as close as possible to the actual time that the sample will be in contact with the bottle. After standing, the water is analyzed.
- 17.4 **Bubbler Blank**—For this Method, the bubbler blank is specific to the bubbler system and is used to determine that the analytical system is free from contamination. After analysis of a standard, blank, or sample, the solution in the bubbler is purged and analyzed. A minimum of three bubbler blanks is required for system calibration.
- 17.5 **Equipment Blank**—Reagent water that has been processed through the sampling device at a laboratory or other equipment cleaning facility prior to shipment of the sampling equipment to the sampling site. The equipment blank is used to demonstrate that the sampling equipment is free from contamination prior to use. Where appropriate, the "clean hands/dirty hands" technique used during field sampling should be followed when preparing equipment blanks at the laboratory or cleaning facility.
- 17.6 **Field Blank**—Reagent water that has been transported to the sampling site and exposed to the same equipment and operations as a sample at the sampling site. The field blank is used to demonstrate that the sample has not been contaminated by the sampling and sample transport systems.
- 17.7 **Intercomparison Study**—An exercise in which samples are prepared and split by a reference laboratory, then analyzed by one or more testing laboratories and the reference laboratory. The intercomparison, with a reputable laboratory as the reference laboratory, serves as the best test of the precision and accuracy of the analyses at natural environmental levels.

- 17.8 **Matrix Spike (MS) and Matrix Spike Duplicate (MSD)**—Aliquots of an environmental sample to which known quantities of the analyte(s) of interest is added in the laboratory. The MS and MSD are analyzed exactly like a sample. Their purpose is to quantify the bias and precision caused by the sample matrix. The background concentrations of the analytes in the sample matrix must be determined in a separate aliquot and the measured values in the MS and MSD corrected for these background concentrations.
- 17.9 **May**—This action, activity, or procedural step is allowed but not required.
- 17.10 **May not**—This action, activity, or procedural step is prohibited.
- 17.11 **Method blank**— Method blanks are used to determine the concentration of mercury in the analytical system during sample preparation and analysis, and consist of a volume of reagent water that is carried through the entire sample preparation and analysis. Method blanks are prepared by placing reagent water in a sample bottle and analyzing the water using reagents and procedures identical to those used to prepare and analyze the corresponding samples. A minimum of three method blanks is required with each analytical batch.
- 17.12 **Minimum Level (ML)**—The lowest level at which the entire analytical system must give a recognizable signal and acceptable calibration point for the analyte. It is equivalent to the concentration of the lowest calibration standard, assuming that all method-specified sample weights, volumes, and cleanup procedures have been employed. The ML is calculated by multiplying the MDL by 3.18 and rounding the result to the number nearest to $(1, 2, \text{ or } 5) \times 10^n$, where n is an integer (See Section 1.5).
- 17.13 **Must**—This action, activity, or procedural step is required.
- 17.14 **Quality Control Sample (QCS)**—A sample containing Hg at known concentrations. The QCS is obtained from a source external to the laboratory, or is prepared from a source of standards different from the source of calibration standards. It is used as an independent check of instrument calibration.
- 17.15 **Reagent blank**—Reagent blanks are used to determine the concentration of mercury in the reagents (BrCl , $\text{NH}_2\text{OH}\cdot\text{HCl}$, and SnCl_2) that are used to prepare and analyze the samples. In this Method, reagent blanks are required when each new batch of reagents is prepared.
- 17.16 **Reagent Water**—Water demonstrated to be free of mercury at the MDL of this Method. It is prepared from 18 M Ω ultrapure deionized water starting from a prepurified source. Reagent water is used to wash bottles, as trip and field blanks, and in the preparation of standards and reagents.
- 17.17 **Regulatory Compliance Limit**—A limit on the concentration or amount of a pollutant or contaminant specified in a nationwide standard, in a permit, or otherwise established by a regulatory authority.
- 17.18 **Shall**—This action, activity, or procedure is required.
- 17.19 **Should**—This action, activity, or procedure is suggested, but not required.

- 17.20 Stock Solution**— A solution containing an analyte that is prepared from a reference material traceable to NIST, or a source that will attest to the purity and authenticity of the reference material.
- 17.21 System Blank**— For this Method, the system blank is specific for the flow-injection system and is used to determine contamination in the analytical system and in the reagents used to prepare the calibration standards. A minimum of three system blanks is required during system calibration.
- 17.22 Ultraclean Handling**— A series of established procedures designed to ensure that samples are not contaminated during sample collection, storage, or analysis.

18.0 Tables and Figures

Table 1

Lowest Ambient Water Quality Criterion for Mercury and the Method Detection Limit and Minimum Level of Quantitation for EPA Method 1631

Metal	Lowest Ambient Water Quality Criterion ⁽¹⁾	Method Detection Limit (MDL) and Minimum Level (ML)	
		MDL ⁽²⁾	ML ⁽³⁾
Mercury (Hg)	1.3 ng/L	0.2 ng/L	0.5 ng/L

1. Lowest water quality criterion for the Great Lakes System (Table 4, 40 CFR 132.6).
The lowest Nationwide criterion is 12 ng/L (40 CFR 131.36).
2. Method detection limit (40 CFR 136, Appendix B)
3. Minimum level of quantitation (see Glossary)

Table 2

Quality Control Acceptance Criteria for Performance Tests in EPA Method 1631

Acceptance Criteria	Section	Limit (%)
Initial Precision and Recovery (IPR)	9.2.2	
Precision (RSD)	9.2.2.3	21
Recovery (X)	9.2.2.3	79-121
Ongoing Precision and Recovery (OPR)	9.5.2	77-123
Matrix Spike/Matrix Spike Duplicate (MS/MSD)	9.3	
Recovery	9.3.4	71-125
Relative Percent Difference (RPD)	9.3.5	24

Table 3

**Precision and Recovery for Reagent Water, Fresh Water, Marine Water, and Effluent Water
Using Method 1631**

Matrix	*Mean Recovery (%)	*Precision (% RSD)
Reagent Water	98.0	5.6
Fresh Water (Filtered)	90.4	8.3
Marine Water (Filtered)	92.3	4.7
Marine Water (Unfiltered)	88.9	5.0
Secondary Effluent (Filtered)	90.7	3.0
Secondary Effluent (Unfiltered)	92.8	4.5

*Mean percent recoveries and RSDs are based on expected Hg concentrations.

Introduction

This analytical method supports water quality monitoring programs authorized under the Clean Water Act (CWA, the "Act"). CWA Section 304(a) requires EPA to publish water quality criteria that reflect the latest scientific knowledge concerning the physical fate (e.g., concentration and dispersal) of pollutants, the effects of pollutants on ecological and human health, and the effect of pollutants on biological community diversity, productivity, and stability.

CWA Section 303 requires each state to set a water quality standard for each body of water within its boundaries. A state water quality standard consists of a designated use or uses of a water body or a segment of a water body, the water quality criteria that are necessary to protect the designated use or uses, and an antidegradation policy. These water quality standards serve two purposes: (1) they establish the water quality goals for a specific water body, and (2) they are the basis for establishing water quality-based treatment controls and strategies beyond the technology-based controls required by CWA Sections 301(b) and 306.

In defining water quality standards, the state may use narrative criteria, numeric criteria, or both. However, the 1987 amendments to CWA required states to adopt numeric criteria for toxic pollutants (designated in Section 307(a) of the Act) based on EPA Section 304(a) criteria or other scientific data, when the discharge or presence of those toxic pollutants could reasonably be expected to interfere with designated uses.

In some cases, these water quality criteria are as much as 280 times lower than those achievable using existing EPA methods and required to support technology-based permits. Therefore, EPA developed new sampling and analysis methods to specifically address state needs for measuring toxic metals at water quality criteria levels, when such measurements are necessary to protect designated uses in state water quality standards. The latest criteria published by EPA are those listed in the National Toxics Rule (58 *FR* 60848) and the Stay of Federal Water Quality Criteria for Metals (60 *FR* 22228). These rules include water quality criteria for 13 metals, and it is these criteria on which the new sampling and analysis methods are based. Method 1630 was specifically developed to provide reliable measurements of methyl mercury at EPA WQC levels.

In developing methods for determination of trace metals, EPA found that one of the greatest difficulties was precluding sample contamination during collection, transport, and analysis. The degree of difficulty, however, is highly dependent on the metal and site-specific conditions. This method is designed to preclude contamination in nearly all situations. It also contains procedures necessary to produce reliable results at the lowest ambient water quality criteria published by EPA. In recognition of the variety of situations to which this method may be applied, and in recognition of continuing technological advances, Method 1630 is performance based. Alternative procedures may be used so long as those procedures are demonstrated to yield reliable results.

Requests for additional copies of this method should be directed to:

U.S. EPA NCEPI
11209 Kenwood Road
Cincinnati, OH 45242
513/489-8190

Note: This method is performance based. The laboratory is permitted to omit any step or modify any procedure provided that all performance requirements in this method are met. The laboratory may not omit any quality control analyses. The terms “shall,” “must,” and “may not” define procedures required for producing reliable data at water quality criteria levels. The terms “should” and “may” indicate optional steps that may be modified or omitted if the laboratory can demonstrate that the modified method produces results equivalent or superior to results produced by this method.

Method 1630

Methyl Mercury in Water by Distillation, Aqueous Ethylation, Purge and Trap, and CVAFS

1.0 Scope and Application

- 1.1** This method is for determination of methyl mercury (CH_3Hg) in filtered and unfiltered water by distillation, aqueous ethylation, purge and trap, desorption, and cold-vapor atomic fluorescence spectrometry (CVAFS). This method is for use in EPA's data gathering and monitoring programs associated with the Clean Water Act, the Resource Conservation and Recovery Act, the Comprehensive Environmental Response, Compensation and Liability Act, and the Safe Drinking Water Act. The method is based on a contractor-developed method (Reference 1) and on peer-reviewed, published procedures for the determination of CH_3Hg in aqueous samples, ranging from sea water to sewage effluent (References 2-7).
- 1.2** This method is accompanied by Method 1669: *Sampling Ambient Water for Determination of Trace Metals at EPA Water Quality Criteria Levels* (Sampling Method). The Sampling Method is necessary to preclude contamination during the sampling process.
- 1.3** This method is designed for determination of CH_3Hg in the range of 0.02-5 ng/L and may be extended to higher levels by selection of a smaller sample size.
- 1.4** The ease of contaminating ambient water samples with the metal(s) of interest and interfering substances cannot be overemphasized. This method includes suggestions for improvements in facilities and analytical techniques that should maximize the ability of the laboratory to make reliable trace metal determinations and minimize contamination (Section 4.0).
- 1.5** The detection limit and minimum level of quantitation in this method are usually dependent on the level of background elements rather than instrumental limitations. The method detection limit (MDL; 40 *CFR* 136, Appendix B) for CH_3Hg has been determined to be 0.02 ng/L when no background elements or interferences are present. The minimum level (ML) has been established as 0.06 ng/L. An MDL as low as 0.009 ng/L can be achieved for low CH_3Hg samples by using extra caution in sample handling and reagent selection, particularly the use of "for ultra-low level only" distillation equipment.
- 1.6** Clean and ultraclean—The terms "clean" and "ultraclean" have been applied to the techniques needed to reduce or eliminate contamination in trace metal determinations. These terms are not used in this method because they lack an exact definition. However, the information provided in this method is consistent with the summary guidance on clean and ultraclean techniques.
- 1.7** This method follows the EPA Environmental Methods Management Council's "Format for Method Documentation."
- 1.8** This method is "performance based." The analyst is permitted to modify the method to overcome interferences or lower the cost of measurements if all performance criteria are met. Section 9.1.2 gives the requirements for establishing method equivalency.

- 1.9** Any modification of this method, beyond those expressly permitted, shall be considered a major modification subject to application and approval of alternate test procedures under 40 *CFR* 136.4 and 136.5.
- 1.10** This method should be used only by analysts who are experienced in the use of CVAFS techniques and who are thoroughly trained in the sample handling and instrumental techniques described in this method. Each analyst who uses this method must demonstrate the ability to generate acceptable results using the procedure in Section 9.2.
- 1.11** This method is accompanied by a data verification and validation guidance document, *Guidance on the Documentation and Evaluation of Trace Metals Data Collected for CWA Compliance Monitoring*. Data users should state data quality objectives (DQOs) required for a project before this method is used.

2.0 Summary of Method

- 2.1** A 100-2000 mL sample is collected directly into specially cleaned, pretested, fluoropolymer or borosilicate bottle(s) using sample handling techniques specially designed for collection of metals at trace levels (Reference 6).
- 2.2** For dissolved CH_3Hg , samples are filtered through a 0.45- μm capsule filter.
- 2.3** Fresh water samples are preserved by adding 4 mL/L of pretested 11.6 M HCl, while saline samples ($[\text{Cl}^-] > 500$ ppm) are preserved with 2 mL/L of 9 M H_2SO_4 solution, to avoid distillation interferences caused by excess chloride.
- 2.4** Prior to analysis, a 45-mL sample aliquot is placed in a specially designed fluoropolymer distillation vessel, and 35 mL of the water is distilled into the receiving vessel at 125°C under N_2 flow.
- 2.5** After distillation, the sample is adjusted to pH 4.9 with an acetate buffer and ethylated in a closed purge vessel by the addition of sodium tetraethyl borate (NaBEt_4).
- 2.6** The ethyl analog of CH_3Hg , methylethyl mercury ($\text{CH}_3\text{CH}_2\text{CH}_2\text{Hg}$), is separated from solution by purging with N_2 onto a graphitic carbon (Carbotrap[®]) trap.
- 2.7** The trapped methylethyl mercury is thermally desorbed from the Carbotrap[®] trap into an inert gas stream that carries the released methylethyl mercury first through a pyrolytic decomposition column, which converts organo mercury forms to elemental mercury (Hg^0), and then into the cell of a cold-vapor atomic fluorescence spectrometer (CVAFS) for detection.
- 2.8** Quality is ensured through calibration and testing of the distillation, ethylation, purging, and detection systems.

3.0 Definitions

- 3.1** Apparatus: Throughout this method, the sample containers, sampling devices, instrumentation, and all other materials and devices used in sample collection, sample processing, and sample analysis that come in contact with the sample and therefore require careful cleaning will be referred to collectively as the Apparatus.
- 3.2** Dissolved methyl mercury: All distillable CH_3Hg forms and species found in the filtrate of an aqueous solution that has been filtered through a 0.45 micron filter.
- 3.3** Methyl mercury: All acid-distillable Hg, which, upon reaction with NaBEt_4 yields methylethyl mercury. This includes, but is not limited to, CH_3Hg^+ , strongly organo-complexed CH_3Hg compounds, adsorbed particulate CH_3Hg , and CH_3Hg bound in microorganisms. In freshly collected samples, dimethyl mercury ($(\text{CH}_3)_2\text{Hg}$) will not be recovered as CH_3Hg , but in samples which have been acidified for several days, most $(\text{CH}_3)_2\text{Hg}$ has broken down to CH_3Hg . In this method, CH_3Hg and total recoverable CH_3Hg are synonymous.
- 3.4** Definitions of other terms used in this method are given in the glossary at the end of the method.

4.0 Contamination and Interferences

- 4.1** Preventing ambient water samples from becoming contaminated during the sampling and analysis process constitutes one of the greatest difficulties encountered in trace metals determinations. Over the last two decades, marine chemists have come to recognize that much of the historical data on the concentrations of dissolved trace metals in seawater are erroneously high because the concentrations reflect contamination from sampling and analysis rather than ambient levels. Therefore, it is imperative that extreme care be taken to avoid contamination when collecting and analyzing ambient water samples for trace metals.
- 4.2** Samples may become contaminated by numerous routes. Potential sources of trace metal contamination during sampling include: metallic or metal-containing labware (e.g., talc gloves that contain high levels of zinc), containers, sampling equipment, reagents, and reagent water; improperly cleaned and stored equipment, labware, and reagents; and atmospheric inputs such as dirt and dust. Even human contact can be a source of trace metal contamination. For example, it has been demonstrated that dental work (e.g., mercury amalgam fillings) in the mouths of laboratory personnel can contaminate samples that are directly exposed to exhalation (Reference 5).
- 4.3** Contamination control
- 4.3.1** Philosophy—The philosophy behind contamination control is to ensure that any object or substance that contacts the sample is metal free and free from any material that may contain Hg or CH_3Hg .

- 4.3.1.1** The integrity of the results produced cannot be compromised by contamination of samples. This method and the Sampling Method give requirements and suggestions for control of sample contamination.
 - 4.3.1.2** Substances in a sample cannot be allowed to contaminate the laboratory work area or instrumentation used for trace metals measurements. This method gives requirements and suggestions for protecting the laboratory.
 - 4.3.1.3** Although contamination control is essential, personnel health and safety remain the highest priority. The Sampling Method and Section 5 of this method give requirements and suggestions for personnel safety.
- 4.3.2** Avoid contamination—The best way to control contamination is to completely avoid exposure of the sample to contamination in the first place. Avoiding exposure means performing operations in an area known to be free from contamination. Two of the most important factors in avoiding/reducing sample contamination are (1) an awareness of potential sources of contamination and (2) strict attention to the work being done. Therefore, it is imperative that the procedures described in this method be carried out by well-trained, experienced personnel.
- 4.3.3** Use a clean environment—The ideal environment for processing samples is a class 100 clean room. If a clean room is not available, all sample preparation should be performed in a class 100 clean bench or a nonmetal glove box fed by mercury-free and particle-free air or nitrogen. Digestions should be performed in a nonmetal fume hood situated, ideally in the clean room.
- 4.3.4** Minimize exposure—The Apparatus that will contact samples, blanks, or standard solutions should be opened or exposed only in a clean room, clean bench, or glove box so that exposure to an uncontrolled atmosphere is minimized. When not in use, the Apparatus should be covered with clean plastic wrap, stored in the clean bench or in a plastic box or glove box, or bagged in clean zip-type bags. Minimizing the time between cleaning and use will also minimize contamination.
- 4.3.5** Clean work surfaces—Before a given batch of samples is processed, all work surfaces in the hood, clean bench, or glove box in which the samples will be processed should be cleaned by wiping with a lint-free cloth or wipe soaked with reagent water.
- 4.3.6** Wear gloves—Sampling personnel must wear clean, non talc gloves during all operations involving handling of the Apparatus, samples, and blanks. Only clean gloves may touch the Apparatus. If another object or substance is touched, the glove(s) must be changed before again handling the Apparatus. If it is even suspected that gloves have become contaminated, work must be halted, the contaminated gloves removed, and a new pair of clean gloves put on. Wearing multiple layers of clean gloves will allow the old pair to be quickly stripped with minimal disruption to the work activity.

- 4.3.7** Use metal-free Apparatus—All Apparatus used for determination of CH₃Hg at ambient water quality criteria levels must be nonmetallic and free of material that may contain metals.
- 4.3.7.1** Construction materials—Only fluoropolymer or borosilicate glass containers should be used for samples that will be analyzed for Hg because Hg vapors can diffuse in or out of other materials, resulting in results that are biased low or high. All materials, regardless of construction, that will directly or indirectly contact the sample must be cleaned using the procedures in this method and must be known to be clean and mercury free before proceeding.
- 4.3.7.2** Serialization—It is recommended that serial numbers be indelibly marked or etched on each piece of Apparatus so that contamination can be traced, and logbooks should be maintained to track the sample from the container through the labware to introduction into the instrument. It may be useful to dedicate separate sets of labware to different sample types; e.g., receiving waters vs. effluents. However, the Apparatus used for processing blanks and standards must be mixed with the Apparatus used to process samples so that contamination of all labware can be detected.
- 4.3.7.3** The laboratory or cleaning facility is responsible for cleaning the Apparatus used by the sampling team. If there are any indications that the Apparatus is not clean when received by the sampling team (e.g., ripped storage bags), an assessment of the likelihood of contamination must be made. Sampling must not proceed if it is possible that the Apparatus is contaminated. If the Apparatus is contaminated, it must be returned to the laboratory or cleaning facility for proper cleaning before any sampling activity resumes.
- 4.3.8** Avoid sources of contamination—Avoid contamination by being aware of potential sources and routes of contamination.
- 4.3.8.1** Contamination by carryover—Contamination may occur when a sample containing a low concentration of CH₃Hg is processed immediately after a sample containing a relatively high concentration. When an unusually concentrated sample is encountered, a ethylation blank should be analyzed immediately following the sample to check for carryover. Samples known or suspected to contain the lowest concentration of CH₃Hg should be analyzed first followed by samples containing higher levels.
- 4.3.8.2** Contamination by samples—Significant laboratory or instrument contamination may result when untreated effluents, in-process waters, landfill leachates, and other samples containing high concentrations of Hg or CH₃Hg are processed and analyzed. This method is not intended for application to these samples, and samples containing high concentrations

of trace metals should not be permitted into the clean room and laboratory dedicated for processing trace metals samples.

4.3.8.3 Contamination by indirect contact—Apparatus that may not directly come in contact with the samples may still be a source of contamination. For example, clean tubing placed in a dirty plastic bag may pick up contamination from the bag and subsequently transfer the contamination to the sample. Therefore, it is imperative that every piece of the Apparatus that is directly or indirectly used in the collection, processing, and analysis of samples be thoroughly cleaned (see Section 6.1.2).

4.3.8.4 Contamination by airborne particulate matter—Airborne particles are less obvious substances capable of contaminating samples. Samples may be contaminated by airborne dust, dirt, particles, or vapors from unfiltered air supplies; nearby corroded or rusted pipes, wires, or other fixtures; or metal-containing paint. Whenever possible, sample processing and analysis should occur as far as possible from sources of airborne contamination.

4.4 Interferences

4.4.1 When the method is properly applied, no significant interferences have been observed in the analysis of ambient waters.

4.4.2 Distillation of CH_3Hg from solution requires a carefully controlled level of HCl in solution. Distillation will not be quantitative if too little HCl is added, but too much HCl results in co-distillation of HCl fumes, which interfere with the ethylation procedure. Therefore fresh water samples must be preserved only with between 0.3% and 0.5% (v/v) 11.6 M HCl, and salt water samples with between 0.1% and 0.2% (v/v) 9 M H_2SO_4 .

4.4.3 Samples preserved with nitric acid (HNO_3) cannot be analyzed for CH_3Hg as the analyte is partially decomposed in the distillation step by this reagent.

4.4.4 The fluorescent intensity is strongly dependent upon the presence of molecular species in the carrier gas that can cause "quenching" of the excited atoms. The Carbotrap[®] trap eliminates quenching due to trace gases, but it still remains the analyst's responsibility to ensure high purity inert carrier gas and a leak-free analytical train. In some rare cases (such as oil polluted water) low molecular weight organic compounds may purge with the methylethyl mercury and collect on the Carbotrap[®] trap, subsequently resulting in signal quenching during elution. Such cases are best treated by sample dilution prior to distillation.

4.4.5 Recent investigations have shown that a positive artifact is possible with the distillation procedure in cases where high inorganic Hg concentrations are present (Reference 7). In natural waters, approximately 0.01 to 0.05% of the ambient inorganic Hg in solution may be methylated by ambient organic matter during the distillation step. In most waters, where the percent CH_3Hg is 1-30% of the total, this effect is trivial. However, the analyst

should be aware that in inorganic Hg contaminated waters, the fraction CH₃Hg can be < 1% of the total, and so flagging of the data (as representing a maximum estimate of CH₃Hg concentration) may be warranted. In samples with high levels of divalent mercury (Hg(II)), solvent extraction may be preferable to distillation (Reference 7).

5.0 Safety

5.1 The toxicity or carcinogenicity of each chemical used in this method has not been precisely determined; however, each compound should be treated as a potential health hazard. Exposure to these compounds should be reduced to the lowest possible level. It is suggested that the laboratory perform personal hygiene monitoring of each analyst using this method and that the results of this monitoring be made available to the analyst.

5.1.1 Chronic Hg exposure may cause kidney damage, muscle tremors, spasms, personality changes, depression, irritability, and nervousness. Organo-mercurials may cause permanent brain damage. Because of the toxicological and physical properties of CH₃Hg, pure standards should be handled only by highly trained personnel thoroughly familiar with handling and cautionary procedures and the associated risks.

5.1.2 It is recommended that the laboratory purchase a dilute standard solution of CH₃Hg for this method. If primary solutions are prepared, they shall be prepared in a hood, and a NIOSH/MESA-approved toxic gas respirator shall be worn when high concentrations are handled.

5.2 This method does not address all safety issues associated with its use. The laboratory is responsible for maintaining a current awareness file of OSHA regulations for the safe handling of the chemicals specified in this method. A reference file of material safety data sheets (MSDSs) should also be made available to all personnel involved in these analyses. Additional information on laboratory safety can be found in References 7-10. The references and bibliography at the end of Reference 10 are particularly comprehensive in dealing with the general subject of laboratory safety.

5.3 Samples suspected of containing high concentrations of CH₃Hg are handled using essentially the same techniques employed in handling radioactive or infectious materials. Well-ventilated, controlled access laboratories are required. Assistance in evaluating the health hazards of particular laboratory conditions may be obtained from certain consulting laboratories and from State Departments of Health or Labor, many of which have an industrial health service. Each laboratory must develop a strict safety program for handling CH₃Hg.

5.3.1 Facility—When samples known or suspected to contain high concentrations of CH₃Hg are handled, all operations (including removal of samples from sample containers, weighing, transferring, and mixing) should be performed in a glove box demonstrated to be leakproof or in a fume hood demonstrated to have adequate airflow. Gross losses to the laboratory ventilation system must not be allowed. Handling of the dilute solutions normally used in analytical and animal work presents no inhalation hazard except in an accident.

- 5.3.2** Protective equipment—Disposable plastic gloves, apron or lab coat, safety glasses or mask, and a glove box or fume hood adequate for radioactive work should be used. During analytical operations that may give rise to aerosols or dusts, personnel should wear respirators equipped with activated carbon filters.
- 5.3.3** Training—Workers must be trained in the proper method of removing contaminated gloves and clothing without contacting the exterior surfaces.
- 5.3.4** Personal hygiene—Hands and forearms should be washed thoroughly after each manipulation and before breaks (coffee, lunch, and shift).
- 5.3.5** Confinement—Isolated work areas posted with signs, segregated glassware and tools, and plastic absorbent paper on bench tops will aid in confining contamination.
- 5.3.6** Effluent vapors—The effluent from the CVAFS should pass through either a column of activated charcoal or a trap containing gold or sulfur to amalgamate or react with Hg vapors.
- 5.3.7** Waste handling—Good technique includes minimizing contaminated waste. Plastic bag liners should be used in waste cans. Janitors and other personnel must be trained in the safe handling of waste.
- 5.3.8** Decontamination
- 5.3.8.1** Decontamination of personnel—Use any mild soap with plenty of scrubbing action.
- 5.3.8.2** Glassware, tools, and surfaces—Activated carbon powder will adsorb CH_3Hg , eliminating the possible volatilization of CH_3Hg . Satisfactory cleaning may be accomplished by dusting a surface lightly with activated carbon powder, then washing with any detergent and water.
- 5.3.9** Laundry—Clothing known to be contaminated should be collected in plastic bags. Persons who convey the bags and launder the clothing should be advised of the hazard and trained in proper handling. If the launderer knows of the potential problem, the clothing may be put into a washer without contact. The washer should be run through a cycle before being used again for other clothing.
- 5.3.10** Wipe tests—A useful method of determining cleanliness of work surfaces and tools is to wipe the surface with a piece of filter paper. Extraction and analysis by this method can achieve a limit of detection of less than 1 ng per wipe. Less than 0.1 μg per wipe indicates acceptable cleanliness; anything higher warrants further cleaning. More than 10 μg on a wipe constitutes an acute hazard, requires prompt cleaning before further use of the equipment or work space, and indicates that unacceptable work practices have been employed.

6.0 Equipment and Supplies

NOTE: *The mention of trade names or commercial products in this method is for illustrative purposes only and does not constitute endorsement or recommendation for use by the Environmental Protection Agency. Equivalent performance may be achievable using apparatus, materials, or cleaning procedures other than those suggested here. The laboratory is responsible for demonstrating equivalent performance.*

6.1 Sampling equipment

6.1.1 Sample collection bottles—fluoropolymer or borosilicate glass, 125- to 1000-mL, with fluoropolymer or fluoropolymer-lined cap.

6.1.2 Cleaning

6.1.2.1 New bottles are cleaned by heating to 65-75°C in 4 N HCl for at least 48 h. The bottles are cooled, rinsed three times with reagent water, and filled with reagent water containing 1% HCl. These bottles are capped and placed in a clean oven at 60-70°C overnight. After cooling, they are rinsed three more times with reagent water, filled with reagent water containing 0.4% (v/v) HCl, capped, and placed in a mercury-free class 100 clean bench until the outside of the bottle is dry. The caps are then tightened with a wrench and the bottles are double-bagged in new polyethylene zip-type bags. The capped bottles are stored in wooden or plastic boxes until use.

6.1.2.2 To avoid long-term accumulation of Hg or CH₃Hg on the bottle walls due to trace organic coatings, used bottles are filled with reagent water containing 0.02 N BrCl solution and allowed to stand over night. The BrCl is neutralized with the addition of 0.2 mL of 20% NH₂OH solution. The bottles are then cleaned exactly as in Section 6.1.2.1, except that they soak only 6-12 h in hot 4 N HCl.

6.1.2.3 Bottle blanks should be analyzed as described in Section 9.4.4.1 to verify the effectiveness of the cleaning procedures.

6.1.3 Filtration Apparatus

6.1.3.1 Filter—0.45- μ m, 15-mm diameter capsule filter (Gelman Supor 12175, or equivalent)

6.1.3.2 Peristaltic pump—115-V a.c., 12-V d.c., internal battery, variable-speed, single-head (Cole-Parmer, portable, "Masterflex L/S," Catalog No. H-07570-10 drive with Quick Load pump head, Catalog No. H-07021-24, or equivalent).

6.1.3.3 Tubing—styrene/ethylene/butylene/silicone (SEBS) resin for use with peristaltic pump, approx 3/8-in i.d. by approximately 3 ft (Cole-Parmer size 18, Catalog No. G-06464-18, or approximately 1/4-in i.d., Cole-Parmer size 17, Catalog No. G-06464-17, or equivalent). Tubing is cleaned by soaking in 5-10% HCl solution for 8-24 h. It is rinsed with reagent water on a clean bench in a clean room and dried on the clean bench by purging with metal-free air or nitrogen. After drying, the tubing is double-bagged in clear polyethylene bags, serialized with a unique number, and stored until use.

6.2 Equipment for bottle and glassware cleaning

6.2.1 Vat, 100-200 L, high-density polyethylene (HDPE), half filled with 4 N HCl in reagent water.

6.2.2 Panel immersion heater, 500-W, all-fluoropolymer coated, 120 vac (Cole-Parmer H-03053-04, or equivalent)

NOTE: *Read instructions carefully!! The heater will maintain steady state, without temperature feedback control, of 60-75°C in a vat of the size described. However, the equilibrium temperature will be higher (up to boiling) in a smaller vat. Also, the heater plate MUST be maintained in a vertical position, completely submerged and away from the vat walls to avoid melting the vat or burning out!*

6.2.3 Laboratory sink in class 100 clean area, with high-flow reagent water (Section 7.1) for rinsing.

6.2.4 Clean bench, class 100, for drying rinsed bottles.

6.2.5 Oven, stainless steel, in class 100 clean area, capable of maintaining $\pm 5^\circ\text{C}$ in the 60-70°C temperature range.

6.3 Cold vapor atomic fluorescence spectrometer (CVAFS): The CVAFS system used may either be purchased from a supplier, or built in the laboratory from commercially available components.

6.3.1 Commercially available: Tekran Model 2357 CVAFS, Brooks-Rand Model III CVAFS, or equivalent

6.3.2 Custom-built CVAFS (Reference 11). Figure 1 shows the schematic diagram. The system consists of the following:

6.3.2.1 Low-pressure 4-W mercury vapor lamp

6.3.2.2 Far UV quartz flow-through fluorescence cell—12 mm x 12 mm x 45 mm, with a 10-mm path length (NSG Cells, or equivalent).

-
- 6.3.2.3** UV-visible photomultiplier (PMT)—sensitive to < 230 nm. This PMT is isolated from outside light with a 253.7-nm interference filter (Oriel Corp., or equivalent).
 - 6.3.2.4** Photometer and PMT power supply (Oriel Corp., or equivalent), to convert PMT output (nanoamp) to millivolts
 - 6.3.2.5** Black anodized aluminum optical block—holds fluorescence cell, PMT, and light source at perpendicular angles, and provides collimation of incident and fluorescent beams (Frontier Geosciences Inc., or equivalent).
 - 6.3.2.6** Flowmeter, with needle valve capable of keeping the carrier gas at a reproducible flow rate of 30 mL/min
 - 6.3.2.7** Ultra high-purity argon (grade 5.0)
- 6.4** Equipment for CH₃Hg purging system—Figure 2a shows the schematic diagram for the purging system. The system consists of the following:
- 6.4.1** Flow meter/needle valve—capable of controlling and measuring gas flow rate to the purge vessel at 350 (± 50) mL/min.
 - 6.4.2** Fluoropolymer fittings—connections between components and columns are made using 6.4-mm o.d. fluoropolymer tubing and fluoropolymer friction-fit or threaded tubing connectors. Connections between components requiring mobility are made with 3.2-mm o.d. fluoropolymer tubing because of its greater flexibility.
 - 6.4.3** Cold vapor generator (bubbler)—200-mL borosilicate glass (15 cm high x 5.0 cm diameter) with standard taper 24/40 neck, fitted with a sparging stopper having a coarse glass frit that extends to within 0.2 cm of the bubbler bottom (Frontier Geosciences, Inc., or equivalent).
- 6.5** Equipment for the isothermal gas chromatography (GC) system.
- 6.5.1** Figure 1 shows the schematic for the interface of the GC with the CVAFS detector (Reference 6).
 - 6.5.2** Figure 2b shows the orientation consideration for purging and desorbing CH₃Hg from the Carbotrap[®] traps.
 - 6.5.3** Carbotrap[®] traps—10-cm x 6.5-mm o.d. x 4-mm i.d. quartz tubing. The tube is filled with 3.4 cm of 30/45 mesh Carbotrap[®] graphitic carbon adsorbant (Supelco, Inc., or equivalent). The ends are plugged with silanized glass wool.
 - 6.5.3.1** Traps are fitted with 6.5-mm i.d. fluoropolymer friction-fit sleeves for making connection to the system. When traps are not in use,

fluoropolymer end plugs are inserted in trap ends to eliminate contamination.

6.5.3.2 At least six traps are needed for efficient operation.

6.5.3.3 Because the direction of flow is important in this analysis, the crimped end of the Carbotrap[®] trap will be referred to as “side A,” while the uncrimped end will be referred to as “side B.”

6.5.4 Heating of Carbotrap[®] traps—To desorb CH₃Hg collected on a trap, heat for 45 sec to 450-500 °C (a barely visible red glow when the room is darkened) with a coil consisting of 75 cm of 24-gauge Nichrome wire at a potential of 16-20 vac. Potential is applied and finely adjusted with an autotransformer.

6.5.5 Timer—The heating interval is controlled by a timer-activated 120-V outlet, into which the heating coil autotransformer is plugged.

6.5.6 Isothermal GC—Consists of two parts, a custom fabricated packed GC column, and a custom fabricated constant temperature oven.

6.5.6.1 The column is 1 m long, made from 0.25 inch OD by 4 mm ID borosilicate glass GC column tubing. The column is formed into an 8 cm diameter coil, with 15 cm straight extensions from each end. The column is silanized, packed in the coiled portion with 60/80 mesh 15% OV-3 on acid-washed Chromasorb W, and then conditioned under inert gas flow at 200°C. A column meeting these specifications may be custom fabricated (Supelco Inc., or equivalent).

6.5.6.2 The GC oven consists of a 500-watt aluminum jacketed heating mantle, fitted with a custom machined fluoropolymer lid (14 cm OD by 1 cm thick). The lid is attached with stainless steel screws and contains three threaded holes (0.25 inch female NPT) in a triangular pattern in the top. The spacing of the holes conforms exactly to the spacing between the two 15 cm glass extensions of the GC column.

6.5.6.3 Fluoropolymer fittings, with 0.25-inch male NPT threads on the bottom and 0.25-inch compression fittings on top, are placed into the threaded holes. The GC column is secured into the oven by passing the glass extensions through two of the fluoropolymer fittings, so that 3 cm of the glass extensions protrude from the top, and tightening the compression fittings. The fluoropolymer lid holding the GC column is then screwed to the top of the oven.

6.5.6.4 Temperature feedback control ($110 \pm 2^\circ\text{C}$) is achieved through a thermocouple temperature controller. The oven is plugged into the controller and the thermocouple probe is inserted through the third

fluoropolymer fitting in the lid, such that the sensor is located near the center of the GC coil.

6.5.6.5 Several research groups have successfully interfaced the Carbotrap[®]/CVAFS system directly to a commercial gas chromatograph. The use of capillary column GC will result in better peak separation, although at higher cost.

6.5.7 Pyrolytic column—The output from the GC oven is connected directly to a high temperature column to decompose eluted organo-mercurial compounds to Hg⁰. The output of the pyrolytic column is connected to the inlet of the CVAFS system.

6.5.7.1 The column consists of a 20-cm length of quartz tubing, packed over the central 10 cm with quartz wool.

6.5.7.2 The column is heated to orange heat (~ 700°C) by a 1 m length of 22 gauge Nichrome wire, tightly wrapped around the quartz wool packed portion of the tube. The temperature of the coil is adjusted by visual inspection of the color, using a 0-120 volt autotransformer.

6.6 Recorder—Any multi-range millivolt chart recorder or integrator with a range compatible with the CVAFS is acceptable. By using a two pen recorder with pen sensitivity offset by a factor of 10, the dynamic range of the system is extended to 10³.

6.7 Distillation unit—The distillation unit is a custom made temperature controlled aluminum block heater, as shown schematically in Figure 3 (Frontier Geosciences Inc., or equivalent).

6.7.1 Heating block insulation—Each heating block is encased first in refractory spun rock insulation (1 inch thickness) and then an exterior wood shell for rigidity.

6.7.2 Each heating block (10 cm wide x 20 cm long x 15 cm high) is bored with five 31 mm diameter holes (evenly spaced), 120 mm deep. A 3/8 inch diameter hole is bored to 90% of the block length, perpendicular to and behind the distillation tube holes, to accommodate a cylindrical heating element. A 2 mm diameter hole is bored parallel to the heating element hole, and 2 cm above it, to accommodate the temperature sensor.

6.7.3 Heating element—Each heating block is equipped with a 750 watt cylindrical heating element, 6 inches long by 3/8 inch diameter (Omega Inc.), immobilized in its respective hole by a dab of silicone glue.

6.7.4 Type J thermocouple probe—Each heating block is equipped with a type J thermocouple probe immobilized in its respective hole by a dab of silicone glue.

6.7.5 Digital temperature controller—The heating element and thermocouple are connected to a digital temperature controller.

6.7.6 Fluoropolymer vials with caps—The distillation unit is designed to accommodate 60-mL fluoropolymer vials (part number 0202, Savillex, or equivalent). The original caps are used to close the vials when distillate is to be stored until analysis.

6.7.6.1 For each distillation, two identical vials are needed: a distillation vessel and a receiving vessel. For convenience, each vial should be engraved with a line at 40.0 mL (obtained by weighing 40 g of water in the vial), and a unique identification number, both on the vial and the cap.

6.7.6.2 Fluoropolymer vials are acid cleaned initially as described for other fluoropolymer ware and stored filled with 0.5% HCl. After use, receiving vials are rinsed with reagent water and filled with 0.5% HCL. The tubing is looped around the cap as described in Section 6.7.7.1, and the vials are placed in a 70°C (\pm 5°C) oven overnight. Cleaning is the same for the distillation vials, with the exception that first the vials, caps, and tubing are thoroughly scrubbed with an alkaline detergent and test tube brush to remove any residues from the samples.

6.7.7 Purge caps—The standard caps on the fluoropolymer vials are replaced with purge caps (part number 33-2-2, Savillex, or equivalent) for distillation purposes.

6.7.7.1 Fluoropolymer tubing—each purge cap is threaded with a piece of 1/8 inch fluoropolymer tubing, approximately 30-40 cm long. One end is pulled through one of the holes in the cap, down to a length that will allow it to reach the bottom of the distillation vial when the vial is screwed onto the cap. The bottom end of this tubing is cut at a 45° angle. The outside end of the tubing is cut perpendicularly and is looped around and inserted into the second cap hole when not in use (to keep the system closed and clean).

6.7.8 Aluminum distillation cover—The cover for the heating block consists of a 5 cm high aluminum block of the same cross section as the heating block (10 cm wide x 20 cm long), which has been milled out completely except for a 0.5 cm shell all around. In this lid is placed a series of 5 slots, 0.5 cm wide by 3 cm high, on each of the long sides, to allow passage of the distillation tubing in and out of the distillation vessels.

NOTE: *It is very important that the heating block have an aluminum top covering the vessels, to avoid condensation and refluxing of the sample in the distillation vessels.*

6.7.9 Polyethylene container—Distillate is received and cooled in a fluoropolymer receiving vial supported in an ice bath in a polyethylene container. A box approximately 15 cm wide x 25 cm long x 10 cm high is a convenient container, and holes to accommodate the receiving vials can be cut into the lid of each box. Suitable boxes are generally available at sundries stores as storage containers.

6.7.10 Rotometer/needle valve—Five needle valve/rotometer (0-300 mL/min N₂) assemblies are required, one for each distillation vessel in the heating block. These rotometers can be mounted in banks of 5 for each distillation block, with all rotometers connected to a common gas manifold.

6.7.10.1 Fluoropolymer tubing—Inert gas(N₂ or Ar at 0.5-1 atm) is brought from the regulator to the manifold and from the rotometer outlets to the distillation vials by 1/8 inch fluoropolymer tubing.

6.7.11 The entire distillation set-up can be mounted on a stepped structure or shelving unit, such that the banks of rotometers are on the top and easily adjustable. Below the rotometers are the distillation blocks, and lower still, the ice baths for the receiving vessels.

6.8 Pipettors—All-plastic pneumatic fixed-volume and variable pipettors in the range of 10-uL to 5.0-mL.

6.9 Analytical balance capable of weighing to the nearest 0.01 g.

7.0 Reagents and Standards

7.1 Reagent water—18-MΩ minimum, ultrapure deionized water starting from a prepurified (distilled, reverse osmosis, etc.) source. Water should be monitored for Hg, especially after ion exchange beds are changed.

7.2 Air—It is very important that the laboratory air be low in both particulate and gaseous Hg. Ideally, Hg work should be conducted in a new laboratory with mercury-free paint on the walls. Outside air, which is very low in Hg, should be brought directly into the class 100 clean bench air intake. If this is impossible, air coming into the clean bench can be cleaned for Hg by placing a gold-coated cloth prefilter over the intake.

7.2.1 Gold-coated cloth filter: Soak 2 m² of cotton gauze in 500 mL of 2% gold chloride solution at pH 7. In a hood, add 100 mL of 30% NH₂OH·HCl solution, and homogenize into the cloth with gloved hands. The material will turn black as colloidal gold is precipitated. Allow the mixture to set for several hours, then rinse with copious amounts of reagent water. Squeeze-dry the rinsed cloth, and spread flat on newspapers to air-dry. When dry, fold and place over the intake prefilter of the laminar flow hood.

NOTE: Great care should be taken to avoid contaminating the laboratory with gold dust. This could cause interferences with the analysis if gold becomes incorporated into the samples or equipment. The gilding procedure should be done in a remote laboratory if at all possible.

7.3 Hydrochloric acid—Trace-metal purified reagent HCl containing less than 5 pg/mL Hg. CH₃Hg is not stable in concentrated acid, so the acid does not need to be tested for CH₃Hg.

- 7.4** Sulfuric acid—Trace-metal purified reagent H_2SO_4 containing less than 5 pg/mL Hg. CH_3Hg is not stable in concentrated acid, so the acid does not need to be tested for CH_3Hg .
- 7.5** 1% APDC solution—To 100 mL of reagent water, add 1.0 g of reagent grade APDC (ammonium pyrrolidine dithiocarbamate), and shake to dissolve. The solution is purified by extraction with three 10 mL aliquots of methylene chloride.
- 7.6** Glacial acetic acid—Reagent grade
- 7.7** 2 M Acetate buffer—2 moles of reagent grade sodium acetate (272 g) and 2 moles of reagent grade glacial acetic acid (118 mL) dissolved in reagent water to give a final volume of 1.0 L. To purify the buffer of traces of CH_3Hg , add 0.5 mL of 1% NaBEt_4 and purge the solution overnight with Hg-free N_2 or Ar. This solution has an indefinite lifetime when stored in a fluoropolymer bottle at room temperature.
- 7.8** 1% Sodium tetraethyl borate—This reagent is purchased in 1.0-g air-sealed bottles (Strem Chemical, or equivalent). One hundred milliliters of 2% KOH in reagent water is prepared in a fluoropolymer bottle and chilled to 0°C. The bottle of NaBEt_4 is rapidly opened and approximately 5 mL of the KOH solution poured in. The reagent bottle is capped and shaken to dissolve the NaBEt_4 . This is poured into the 100 mL bottle of KOH solution, and shaken to mix. Immediately, the 1% NaBEt_4 solution in 2% KOH is poured into fifteen (15) 7-mL fluoropolymer bottles, which are capped and placed in a low temperature freezer. For use, one of these bottles is removed and thawed until it starts to form a liquid layer. The reagent is then used until just before all of the ice is melted. Usually this lasts about 3 h if the bottle is placed in the refrigerator between uses.

NOTE: *It is imperative that this reagent be exposed to air a minimum length of time. Thus, when removing reagent, open and close the lid quickly and tightly!*

Frozen bottles of NaBEt_4 will keep for at least one week. If any doubt arises about the quality of the ethylating reagent, make a new batch, as the old material often gives good results for reagent water spikes, but not for environmental samples. Do not use NaBEt_4 solid or solutions if they have a yellow color.

WARNING: *NaBEt_4 is toxic, gives off toxic gases (triethylboron), and is spontaneously combustible. To discard unused portions of ethylating agent and empty bottles, place into a large beaker of 1N HCl in the hood. Triethylboron will bubble off to the air where it is eventually oxidized to harmless boric acid. Leave the acid beaker in the hood indefinitely, or boil down to 1/2 volume to destroy residues before discarding as any acid waste.*

- 7.9** Methyl mercuric chloride(s)—A 5-g bottle of methyl mercuric chloride (s), reagent grade (Strem Chemical, or equivalent).
- 7.10** Stock methyl mercury standard—Either procure certified CH_3Hg solution (Frontier Geosciences Inc., or equivalent) or prepare the stock solutions in the laboratory. Dissolve the contents of an entire 5-g bottle of methyl mercuric chloride in reagent water containing 0.5% (v/v) glacial acetic acid and 0.2% (v/v) HCl in a fluoropolymer bottle. This solution contains 4000-5000 mg/L

CH₃Hg as Hg. It does not have a specific titre because, due to the contamination danger, the methyl mercuric chloride is not weighed. The stock solution has an indefinite lifetime when stored in an amber glass bottle with a fluoropolymer lid at room temperature. Do not make or keep this concentrated stock solution in the trace mercury laboratory.

NOTE: Making a CH₃Hg standard rather than purchasing one requires the laboratory to have available the technology to perform analyses with Method 1631: Mercury in Water by Oxidation, Purge and Trap, and Cold Vapor Atomic Fluorescence Spectrometry. Total Hg and labile Hg (II) determinations, made with Method 1631, are necessary to accurately determine the CH₃Hg concentration of the standards. Additionally, laboratories must be cautioned against assuming that purchased CH₃Hg stock solution will remain constant in concentration. Purchased stock solution has been seen to degrade occasionally, in one case from 1000 mg/L to 4 mg/L.

- 7.11** Secondary methyl mercury standard—Dilute 1.00 mL of stock solution (B) to 1000.0 mL with reagent water containing 0.5% (v/v) glacial acetic acid and 0.2% (v/v) HCl. This solution contains approximately 4-5 mg/L (5.00 ng/mL) CH₃Hg as Hg. The exact CH₃Hg titre is determined as indicated in Sections 7.11.1-7.11.4. The secondary CH₃Hg standard solution has been observed to maintain its titre over a year when stored in a fluoropolymer bottle in the refrigerator.
- 7.11.1** Dilute the secondary standard 1:10 with concentrated BrCl solution (0.100 mL of secondary stock solution added to 0.900 mL BrCl in a small FEP vial). Allow the solution to oxidize for at least 4 h. The total Hg in the dilution may then be analyzed using dual amalgamation/CVAFS, by comparison to a dilution of NIST-3133 (as in Method 1631). A mean of at least seven replicate analyses of the secondary stock solution is necessary to accurately quantify the total Hg concentration of the solution.
- 7.11.2** Analyze the secondary standard for labile Hg(II) using Method 1631 by directly reducing an aliquot of standard solution with SnCl₂, but without prior BrCl oxidation as performed in Section 7.11.1. At least two determinations of labile Hg(II) must be made of the stock solution.
- 7.11.3** Calculate the CH₃Hg in the secondary CH₃Hg standard solution by subtracting the mean labile Hg(II) concentration from the mean total Hg concentration.
- 7.11.4** If the secondary CH₃Hg stock solution drops below 98.0% CH₃Hg, discard the solution and make a fresh secondary solution.
- 7.12** Working methyl mercury standard—Prepare a dilution of the secondary CH₃Hg standard using reagent water containing 0.5% (v/v) glacial acetic acid and 0.2% (v/v) HCl. A convenient concentration for this standard is 1.00 ng/mL CH₃Hg as Hg. This solution will maintain its titre for more than one month when kept in a fluoropolymer bottle on the lab bench top. Refrigeration is not necessary.
- 7.13** IPR and OPR solutions—Using the working CH₃Hg standard (Section 7.9), prepare IPR and OPR solutions at a concentration of 0.5 ng/L as Hg in reagent water.

- 7.14** Nitrogen—Grade 4.5 (standard laboratory grade) nitrogen that has been further purified by the removal of Hg using a gold-coated sand trap (Section 7.16).
- 7.15** Argon—Grade 5.0 (ultra high-purity, GC grade) that has been further purified by the removal of Hg using a gold-coated sand trap (Section 7.16).
- 7.16** Gold-coated sand trap—The trap is made from 10-cm x 6.5-mm o.d. x 4-mm i.d. quartz tubing. The tube is filled with 3.4 cm of gold-coated 45/60 mesh quartz sand (Frontier Geosciences Inc., or equivalent). The ends are plugged with quartz wool. Traps are fitted with 6.5-mm i.d. fluoropolymer friction-fit sleeves for connection to the system.

8.0 Sample Collection, Preservation, and Storage

- 8.1** Before samples are collected, consideration should be given to the type of data required, (i.e., dissolved or total), so that appropriate preservation and pretreatment steps can be taken. The pH of all aqueous samples must be tested immediately before removing an aliquot for processing or direct analysis to ensure the sample has been properly preserved.

NOTE: Do not dip pH paper or pH meter into the sample; remove a small aliquot with a clean pipet and test the aliquot pH.

- 8.2** Samples are collected into rigorously cleaned fluoropolymer bottles with fluoropolymer or fluoropolymer-lined caps. Borosilicate glass bottles may be used if Hg and Hg species are the only target analytes. It is critical that the bottles have tightly sealing caps to avoid diffusion of atmospheric Hg through the threads. Polyethylene sample bottles must not be used (Reference 13).
- 8.3** Collect samples using the Sampling Method (Reference 8). Procedures in the Sampling Method are based on rigorous protocols for collection of samples for Hg (Reference 13).

NOTE: Discrete samplers have been found to contaminate samples with Hg at the ng/L level; therefore, great care should be exercised if this type of sampler is used to collect samples. It may be necessary for the sampling team to use other means of sample collection if samples are found to be contaminated using the discrete sampler.

- 8.4** Sample filtration—For dissolved CH₃Hg, samples and field blanks are filtered through a 0.45- μ m capsule filter (Section 6.1.3.1). The Sampling Method describes filtering procedures.
- 8.5** Preservation—Samples are preserved by adding 4 mL/L of concentrated HCL (to allow both CH₃Hg and total Hg determination). Saline samples ([Cl⁻] $>$ 500 ppm) are preserved with 2 mL/L of 9 M H₂SO₄ solution. Acid-preserved samples are stable for at least six months, if kept dark and cool.
- 8.5.1** Samples may be shipped to the laboratory unpreserved if they are (1) collected in fluoropolymer bottles, (2) filled to the top with no head space, (3) capped tightly, and (4) maintained at 0-4°C from the time of collection until preservation. The samples must be acid-preserved within 48 h of sampling.

- 8.5.2** Handling of the samples in the laboratory should be undertaken on a mercury-free clean bench, after rinsing the outside of the bottles with reagent water and drying in the clean air hood.

NOTE: *Due to the potential for contamination, it is recommended that filtration and preservation of samples be performed in the clean room in the laboratory. However, if circumstances in the field prevent overnight shipment of samples, the samples should be filtered and preserved in a designated clean area in the field in accordance with the procedures given in Sections 8.3 and 8.4 of Method 1669.*

- 8.6** Storage—Sample bottles should be stored in clean (new) polyethylene bags until analysis. To maintain CH₃Hg concentrations without degradation, it is necessary to keep acid-preserved samples dark and cool. If properly preserved, samples can be held up at least six months before analysis.

9.0 Quality Control

- 9.1** Each laboratory that uses this method is required to operate a formal quality assurance program (Reference 14). The minimum requirements of this program consist of an initial demonstration of laboratory capability, ongoing analysis of standards and blanks as a test of continued performance, and the analysis of matrix spikes (MS) and matrix spike duplicates (MSD) to assess accuracy and precision. Laboratory performance is compared to established performance criteria to determine whether the results of analyses meet the performance characteristics of the method.

- 9.1.1** The analyst shall make an initial demonstration of the ability to generate acceptable accuracy and precision with this method. This ability is established as described in Section 9.2.

- 9.1.2** In recognition of advances that are occurring in analytical technology, the analyst is permitted certain options to improve results or lower the cost of measurements. These options include automation of the system, solvent extraction in place of distillation (Reference 2), direct electronic data acquisition, or changes in the detector (i.e., CVAAS, AES, ICP/MS). Changes in the principle of the determinative technique, such as the use of colorimetry, are not allowed. If an analytical technique other than the CVAFS technique specified in this method is used, that technique must have a specificity for CH₃Hg equal to or better than the specificity of the technique in this method.

- 9.1.2.1** Each time this method is modified, the analyst is required to repeat the procedure in Section 9.2. If the change will affect the detection limit of the method, the laboratory is required to demonstrate that the MDL (40 CFR Part 136, Appendix B) is lower than one-third the regulatory compliance level or lower than the MDL of this method, whichever is higher. If the change will affect calibration, the analyst must recalibrate the instrument according to Section 10.

- 9.1.2.2** The laboratory is required to maintain records of modifications made to this method. These records include the following, at a minimum:

- 9.1.2.2.1** The names, titles, addresses, and telephone numbers of the analyst(s) who performed the analyses and modification, and the

quality control officer who witnessed and will verify the analyses and modification

9.1.2.2.2 A narrative stating the reason(s) for the modification(s)

9.1.2.2.3 Results from all quality control (QC) tests comparing the modified method to this method, including the following:

- (a) Calibration (Section 10)
- (b) Initial precision and recovery (Section 9.2)
- (c) Analysis of blanks (Section 9.4)
- (d) Matrix spike/matrix spike duplicate analysis (Section 9.3)
- (e) Ongoing precision and recovery (Section 9.5)
- (f) Quality control sample (Section 9.6)

9.1.2.2.4 Data that will allow an independent reviewer to validate each determination by tracking the instrument output to the final result. These data are to include the following:

- (a) Sample numbers and other identifiers
- (b) Processing dates
- (c) Analysis dates
- (d) Analysis sequence/run chronology
- (e) Sample weight or volume
- (f) Copies of logbooks, chart recorder, or other raw data output
- (g) Calculations linking raw data to the results reported

9.1.3 Analyses of MS and MSD samples are required to demonstrate the accuracy and precision and to monitor matrix interferences. Section 9.3 describes the procedure and QC criteria for spiking.

9.1.4 Analyses of blanks are required to demonstrate acceptable levels of contamination. Section 9.4 describes the procedures and criteria for analyzing blanks.

9.1.5 The laboratory shall, on an ongoing basis, demonstrate through analysis of the ongoing precision and recovery (OPR) sample and the quality control sample (QCS) that the system is in control. Sections 9.5 and 9.6 describe these procedures, respectively.

9.1.6 The laboratory shall maintain records to define the quality of the data that are generated. Sections 9.3.7 and 9.5.3 describe the development of accuracy statements.

9.1.7 The determination of CH₃Hg in water is controlled by an analytical batch. An analytical batch is a set of samples distilled with the same batch of reagents, and analyzed during the same 12-hour shift. A batch may be from 1 to as many as 20 samples. Each batch must be accompanied by at least three method blanks (Section 9.4), an OPR sample, and a QCS. In addition, there must be one MS and one MSD sample for every 10 samples (a frequency of 10%).

9.2 Initial demonstration of laboratory capability

9.2.1 Method detection limit—To establish the ability to detect CH₃Hg, the analyst shall determine the MDL according to the procedure at 40 *CFR* 136, Appendix B using the apparatus, reagents, and standards that will be used in the practice of this method. The laboratory must produce an MDL that is less than or equal to the MDL listed in Section 1.5 or one-third the regulatory compliance limit, whichever is greater. The MDL should be determined when a new operator begins work or whenever, in the judgment of the analyst, a change in instrument hardware or operating conditions would dictate that the MDL be redetermined.

9.2.2 Initial precision and recovery (IPR)—To establish the ability to generate acceptable precision and recovery, the analyst shall perform the following operations:

9.2.2.1 Analyze four replicates of the IPR solution (0.5 ng/L, Section 7.10) according to the procedure beginning in Section 11.

9.2.2.2 Using the results of the set of four analyses, compute the average percent recovery (X), and the standard deviation of the percent recovery (s) for CH₃Hg.

9.2.2.3 Compare s and X with the corresponding limits for initial precision and recovery in Table 2. If s and X meet the acceptance criteria, system performance is acceptable and analysis of samples may begin. If, however, s exceeds the precision limit or X falls outside the acceptance range, system performance is unacceptable. Correct the problem and repeat the test (Section 9.2.2.1).

9.3 Method accuracy—To assess the performance of the method on a given sample matrix, the laboratory must perform either matrix spike (MS) and matrix spike duplicate (MSD) sample analyses on 10% of the samples from each site being monitored, or at least one MS/MSD sample analysis for each sample set, whichever is more frequent.

9.3.1 The concentration of the CH₃Hg in the sample shall be determined as follows:

9.3.1.1 If, as in compliance monitoring, the concentration of CH₃Hg in the sample is being checked against a regulatory concentration limit, the spiking level shall be at that limit or at 1-5 times the background concentration of the sample (as determined in Section 9.3.2), whichever is greater.

9.3.1.2 If the concentration of CH₃Hg in a sample is not being checked against a limit, the spike shall be at 1-5 times the background concentration or at 1-5 times the ML in Table 1, whichever is greater.

9.3.2 Assessing spike recovery

- 9.3.2.1** Determine the background concentration (B) by analyzing one sample aliquot from each set of 10 samples from each site or discharge according to the procedure in Section 11. If the expected background concentration is known from previous experience or other knowledge, the spiking level may be established a priori.
- 9.3.2.2** If necessary, prepare a spiking solution to produce an appropriate level in the sample (Section 9.3.1).
- 9.3.2.3** Spike two sample aliquots with the spiking solution and analyze these aliquots as described in Section 11.1.2 to determine the concentration after spiking (A).
- 9.3.2.4** Calculate the percent recovery (P) in each aliquot using Equation 1:

Equation 1

$$P = 100 * \frac{A - B}{T}$$

Where:

A=Measured concentration of analyte after spiking

B=Measured concentration of analyte before spiking

P=Percent recovery

T=True concentration of the spike

- 9.3.3** Compare the percent recovery (P) with the QC acceptance criteria in Table 2.
- 9.3.3.1** If P falls outside the designated range for recovery in Table 2, the CH₃Hg analysis has failed to meet the established performance criteria. If P is unacceptable, analyze the OPR standard (Section 9.5). If the OPR is within established performance criteria (Table 2), the analytical system is within specification and the problem can be attributed to interference by the sample matrix.
- 9.3.3.2** If the interference can be attributed to sampling, the site or discharge should be resampled. If the interference can be attributed to a method deficiency, the analyst must modify the method, repeat the test required in Section 9.1.2, and repeat analysis of the sample and MS/MSD. However, when this method was written, there were no known interferences in the determination of CH₃Hg using this method. If such a result is observed, the analyst should investigate it thoroughly.
- 9.3.3.3** If the results of both the spike and the OPR test fall outside the acceptance criteria, the analytical system is judged to be outside specified limits. The analyst must identify and correct the problem and reanalyze the sample batch.

- 9.3.4** Relative percent difference between duplicates—Compute the relative percent difference (RPD) between the MS and MSD results according to Equation 2 using the CH₃Hg concentrations found in the MS and MSD. Do not use the recoveries calculated in Section 9.3.2.4 for this calculation because the RPD is inflated when the background concentration is near the spike concentration.

Equation 2

$$RPD = 200 * \frac{|D_1 - D_2|}{D_1 + D_2}$$

Where:

RPD = Relative percent difference

*D*₁ = Concentration of CH₃Hg in the MS sample

*D*₂ = Concentration of CH₃Hg in the MSD sample

- 9.3.5** The RPD for the MS/MSD pair must not exceed the acceptance criterion in Table 2. If the criterion is not met, the system performance is unacceptable. The problem must immediately be identified and corrected, and the analytical batch reanalyzed.
- 9.3.6** As part of the QC program for the laboratory, method precision and accuracy for samples should be assessed and records maintained. After analyzing five samples in which the recovery passes the test in Section 9.3.2, compute the average percent recovery (*P*_a) and the standard deviation of the percent recovery (*s*_p). Express the accuracy assessment as a percent recovery interval from *P*_a - 2*s*_p to *P*_a + 2*s*_p. For example, if *P*_a = 90% and *s*_p = 10% for five analyses, the accuracy interval is expressed as 70-110%. Update the accuracy assessment regularly (e.g., after every five to ten new accuracy measurements).
- 9.4** Blanks—Blanks are critical to the reliable determination of CH₃Hg at low levels. The sections below give the minimum requirements for analysis of blanks. However, it is suggested that additional blanks be analyzed as necessary to pinpoint sources of contamination in, and external to, the laboratory.
- 9.4.1** Ethylation blanks—Reagent water typically contains no CH₃Hg. The reagent (ethylation) blank may conveniently be determined by adding 0.3 mL of acetate buffer and 0.040 mL of 1% NaBEt₄ solution to 50 mL of reagent water in the reaction vessel.

NOTE: Do not ever use a previously ethylated water sample, as a build-up of the gas triethyl boron will occur, which results in a negative interference and poor chromatography.

- 9.4.1.1** A single ethylation blank is analyzed with each analytical run, as part of the calibration sequence. This value is used to blank correct the standard curve.
- 9.4.1.2** The presence of more than 2 pg of CH₃Hg indicates a problem with the reagent water or one of the reagent solutions. An investigation of the cause of the high blank can be made by varying, one at a time, the amounts of buffer, reagent water, and NaBEt₄. Because NaBEt₄ cannot be purified, a new batch should be made from different reagents and should be tested for Hg levels if the level of CH₃Hg is too high. If the reagent water is found high, this can be remedied by replacing the purification cartridges.
- 9.4.2** Method blanks—The method blanks (distillation blanks) are prepared by the distillation and analysis of 45 mL aliquots of 0.4% HCl acidified reagent water, exactly as if they were samples.
- 9.4.2.1** Three method blanks should accompany each analytical batch. The mean blank value should be less than 0.045 ng/L of CH₃Hg, and the variability should be less than 0.015 ng/L of CH₃Hg. A mean blank value greater than 0.045 ng/L CH₃Hg or a variability greater than 0.015 ng/L of CH₃Hg is unacceptable for low level ambient analysis.
- 9.4.3** Field blanks
- 9.4.3.1** Analyze the field blank(s) shipped with each sample set. Analyze the blank immediately before analyzing the samples in the batch.
- 9.4.3.2** If CH₃Hg or any potentially interfering substance is found in the field blank at a concentration equal to or greater than the ML (Table 1), or greater than one-fifth the level in the associated sample, whichever is greater, results for associated samples may be the result of contamination and may not be reported for regulatory compliance purposes.
- 9.4.3.3** Alternatively, if a sufficient number of field blanks (three minimum) are analyzed to characterize the nature of the field blanks, the average concentration plus two standard deviations must be less than the regulatory compliance level or less than one-half the level in the associated sample, whichever is greater.
- 9.4.3.4** If contamination of the field blank(s) and associated samples is known or suspected, the laboratory should communicate this to the sampling team so that the source of contamination can be identified and corrective measures taken before the next sampling event.
- 9.4.4** Equipment blanks—Before any sampling equipment is used at a given site, the laboratory or cleaning facility is required to generate equipment blanks to demonstrate that the

sampling equipment is free from contamination. Two types of equipment blanks are required: bottle blanks and sampler check blanks.

9.4.4.1 Bottle blanks—After undergoing the cleaning procedures in this method, bottles should be subjected to conditions of use to verify the effectiveness of the cleaning procedures. A representative set of sample bottles should be filled with reagent water acidified to 0.4% HCL and allowed to stand for a minimum of 24 h. Ideally, the time that the bottles are allowed to stand should be as close as possible to the actual time that the sample will be in contact with the bottle. After standing, the water should be analyzed for any signs of contamination. If any bottle shows signs of contamination, the problem must be identified, the cleaning procedures corrected or cleaning solutions changed, and all affected bottles cleaned again.

9.4.4.2 Sampler check blanks—Sampler check blanks are generated in the laboratory or at the equipment cleaning contractor's facility by processing reagent water through the sampling devices using the same procedures that are used in the field (see Sampling Method). Therefore, the "clean hands/dirty hands" technique used during field sampling should be followed when preparing sampler check blanks at the laboratory or cleaning facility.

9.4.4.2.1 Sampler check blanks are generated by filling a large carboy (Section 7.17) or other container with reagent water (Section 7.1) and processing the reagent water through the equipment using the same procedures that are used in the field (see Sampling Method). For example, manual grab sampler check blanks are collected by directly submerging a sample bottle into the water, filling the bottle, and capping. Subsurface sampler check blanks are collected by immersing the submersible pump or intake tubing into the water and pumping water into a sample container.

9.4.4.2.2 The sampler check blank must be analyzed using the procedures in this method. If CH_3Hg or any potentially interfering substance is detected in the blank, the source of contamination or interference must be identified, and the problem corrected. The equipment must be demonstrated to be free from CH_3Hg and interferences before the equipment may be used in the field.

9.4.4.2.3 Sampler check blanks must be run on all equipment that will be used in the field. If, for example, samples are to be collected using both a grab sampling device and a subsurface sampling device, a sampler check blank must be run on both pieces of equipment.

- 9.5** Ongoing precision and recovery (OPR)—To demonstrate that the analysis system is within specified limits and that acceptable precision and accuracy is being maintained within each analytical batch, the analyst shall perform the following operations:
- 9.5.1** Analyze the OPR solution (0.5 ng/L, Section 7.10) followed by a ethylation blank prior to the analysis of each analytical batch according to the procedure in Section 11. An OPR must also be analyzed at the end of an analytical run or at the end of each 12-hour shift. Subtract the peak height (or peak area) of the ethylation blank from the peak height (or area) for the OPR and compute the concentration for the blank-subtracted OPR.
- 9.5.2** Compare the computed OPR concentration with the limits in Table 2. If the concentration is in the range specified, the analysis system is within specification and analysis of samples and blanks may proceed. If, however, the concentration is not in the specified range, the analytical process is not within the specified limits. Correct the problem and repeat the OPR test.
- 9.5.3** The laboratory should add results that pass the specification in Section 9.5.2 to IPR and previous OPR data and update QC charts to form a graphic representation of continued laboratory performance. The laboratory should also develop a statement of laboratory data quality for each analyte by calculating the average percent recovery (R) and the standard deviation of the percent recovery (s_r). Express the accuracy as a recovery interval from $R - 2s_r$ to $R + 2s_r$. For example, if $R = 95\%$ and $s_r = 5\%$, the accuracy is 85-105%.
- 9.6** Quality control sample (QCS)—The laboratory must obtain a QCS from a source different from the CH_3Hg used to produce the standards used routinely in this method (Sections 7.7-7.10). The QCS should be analyzed as an independent check of instrument calibration in the middle of the analytical batch (e.g., for a batch of 14 samples, the QCS should be analyzed after the seventh sample). Good QCS samples may be made by KOH/methanol digestion (Reference 2) of CH_3Hg certified tissue CRMs. CH_3Hg certified CRMs are available through the National Institute of Standards Technology (NIST), National Research Council of Canada (NRCC), and International Atomic Energy Agency (IAEA).
- 9.7** Depending on specific program requirements, the laboratory may be required to analyze field duplicates and field spikes collected to assess the precision and accuracy of the sampling, sample transportation, and storage techniques. The relative percent difference (RPD) between field duplicates should be less than 35%. If the RPD of the field duplicates exceeds 35%, the laboratory should communicate this to the sampling team so that the source of error can be identified and corrective measures taken before the next sampling event.

10.0 Calibration and Standardization

- 10.1** Establish the operating conditions necessary to purge Hg species from the bubbler and to desorb Hg species from the traps so that sharp peaks are given. The system is calibrated using CH_3Hg standards ultimately traceable to NIST standard total Hg reference material, as follows:

10.1.1 Calibration

- 10.1.1.1** The calibration must contain five or more non-zero points and the results of analysis of one ethylation blank. The lowest calibration point must be at the minimum level (ML).
- 10.1.1.2** Standards are analyzed by the addition of aliquots of the CH₃Hg working standard (Section 7.9) directly into the bubblers (Section 6.4.3). Add 50 mL of fresh reagent water, a 0.005 ng aliquot of the standard, 0.3 mL of acetate buffer, and 0.04 mL of NaBEt₄ to the bubbler, swirling to mix. Allow to react for 17 min, and then purge and analyze as below (Section 11). Sequentially follow with aliquots of 0.05, 0.1, 0.2, and 0.01 ng CH₃Hg in separate bubblers.
- 10.1.1.3** For each point, correct the standard peak height or area by subtracting the peak height or area of the ethylation blank for the analytical batch. Calculate the calibration factor (CF) for CH₃Hg for each of the five standards using the mean ethylation-blank-corrected peak height or area (Equation 3).

Equation 3

$$CF = \frac{R_s - R_e}{C_s}$$

where:

R_s = Peak height or area of the standard

R_e = Peak height or area of the ethylation blank

C_s = Concentration of the standard (ng/L)

- 10.1.1.4** Calculate the mean calibration factor (CF_m), the standard deviation of the CF_m (SD), and the relative standard deviation (RSD) of the calibration, where RSD = 100 x SD/CF_m. If the RSD is ≤ 15%, the CF_m may be used to calculate sample concentrations. If RSD > 15%, recalibrate the analytical system and repeat the test.
- 10.1.1.5** The net concentration recovery (minus ethylation blank) for the lowest standard must be in the range of 65-135% of the expected value to continue with sample analysis.
- 10.2** Ongoing precision and recovery—Perform the ongoing precision and recovery test to verify calibration prior to analysis of samples in each analytical batch. An OPR must also be analyzed at the end of an analytical run or at the end of each 12-hour shift.

11.0 Procedure

NOTE: *The following procedures for analysis of samples are provided as guidelines. Analysts may find it necessary to optimize the procedures, such as drying time or potential applied to the Nichrome wires, for the laboratory's specific instrumental set-up.*

11.1 Sample Distillation

11.1.1 Weigh a 45-mL aliquot from a thoroughly shaken, acidified sample, into a 60-mL fluoropolymer distillation vial. Add 200 μ L of 1% APDC solution, and replace the distillation cap, such that the tubing extends to the bottom of the vial.

11.1.1.1 Repeat this procedure for all samples to be distilled in a set, including three reagent water blanks and spiked samples.

11.1.1.2 Matrix spikes and matrix spike duplicates—For every 10 or fewer samples, pour two additional 45-mL aliquots from a randomly selected sample. Spike the aliquots at the level specified in Section 9.3 and process them in the same manner as the samples. There should be two MS/MSD pairs for each analytical batch of 20 samples.

11.1.1.3 For each sample, prepare a 60-mL distillate receiving vial. Add 5.0 mL reagent water to each receiving vial and replace the cap so that the tubing extends into the water layer.

11.1.1.4 Record the sample ID associated with each distillation and receiving vial. It is important to develop an unambiguous tracking system, such as the use of engraved vial numbers, because the distillation vials themselves cannot be labeled (due to the heat).

11.1.2 Place each prepared distillation vial into one of the holes in the heating block and attach the fluoropolymer tubing to the incoming gas supply from the rotometer manifold. Adjust the gas flow rate through the bubbler to 60 ± 20 mL/min.

11.1.3 As each distillation vial with sample is placed into the heating block, place the corresponding labeled distillation vial into the ice bath immediately adjacent to the heating block. Attach the tubing from the receiving vessel to the port of the distillation vessel.

11.1.4 Once all the holes in a heating block are filled, place the aluminum lid over the vessel caps in such a way that all tubing is passing without crimps through the slots, and the lid is making metal-to-metal contact with the block (to provide proper heating of the lid).

- 11.1.5** Turn on the temperature controllers to the heating blocks to a pre-set block temperature of $125 \pm 3^\circ\text{C}$.
- 11.1.6** Distill the samples until each receiving vial fills to the engraved 40 mL line. This time period will be approximately 2.5 h to 4 h depending upon exact temperatures, gas flow rates, and water characteristics.
- 11.1.6.1** Different samples and locations on the block will distill at somewhat different rates, so after about 2 h, all of the tubes should be monitored frequently to avoid over-distillation. As the individual samples fill to the line, they should be removed from the distillation unit.
- 11.1.6.2** Over-distillation is the greatest potential risk for poor recoveries by this method. If more than the prescribed amount of sample distills over, the risk of HCl fumes co-distilling increases. Chloride and low pH are interferences with the ethylation procedure.
- 11.1.6.3** If any samples are suspected of over-distillation, they should be checked with pH paper. If the distillate has a pH of less than 3.5, it should be discarded, rather than analyzed.
- 11.1.7** Once all of the vials are distilled, the distillates may be stored at room temperature and in the dark for up to 48 h before analysis (loop the fluoropolymer tube around to close off the second port on the receiving vial). Do not refrigerate or store longer than 48 h.
- 11.1.8** The distillation-side (dirty) vials must be scrubbed thoroughly with a test-tube brush and alkaline detergent, then rinsed in reagent water, to remove organics prior to acid cleaning. To acid-clean between uses, the vials are filled with 10% HCl, recapped with the tubing looped around to close off the port, and placed in an oven at 80°C overnight.
- 11.2** Ethylation and purging of the distillates
- 11.2.1** Immediately before analysis, add 0.3 mL of acetate buffer to the sample in the receiving vial, and then add another 10 mL of reagent water to the vial (so that the total sample volume is > 50 mL; the vial is almost full).
- 11.2.2** Pour the buffered sample into the reaction vessel/bubbler, and add 0.04 mL of freshly thawed 1% NaBEt_4 solution. Close the reaction vessel with the bubbler cap, and swirl gently to mix.
- 11.2.3** If standards, ethylation blanks, or QCS are being analyzed, pour 50 mL of reagent water into the bubbler, add 0.3 mL of acetate buffer, the appropriate spike, etc., and 0.04 mL 1% NaBEt_4 solution.
- 11.2.4** Allow the contents of the bubbler to react for 17 min. All CH_3Hg in the sample is converted to volatile methylethyl mercury.

11.2.5 After reaction, attach a Carbotrap[®] trap to each bubbler with the 1/4" fluoropolymer fitting, and purge the sample with N₂ (200 mL/min) for 17 min.

NOTE: *The Carbotrap[®] trap must be attached such that the gas from the bubbler enters the trap on side A.*

11.2.6 Once the sample has been purged for 17 min, any adsorbed water must be dried from the Carbotrap[®] trap. Disconnect the Carbotrap[®] trap from the bubbler and attach the N₂ flow directly to the trap. Use the same orientation (i.e., N₂ entering from side A), and purge the trap for 7 min.

11.2.7 The sample is now ready for analysis. The methylethyl mercury collected on the trap is quantitatively stable for up to 6 h and must be analyzed within that period.

11.3 Desorption of methylethyl mercury from the Carbotrap[®] trap

11.3.1 Close the argon stopcock on the GC, and allow 30 sec for the pressure in the system to dissipate. Remove the previous Carbotrap[®] trap from the GC.

11.3.2 Attach the Carbotrap[®] trap containing the new sample to the GC column using a 1/4" fluoropolymer friction fit connector, *such that side A is facing toward the GC column.*

11.3.3 Place the Nichrome wire heating coil around the Carbotrap[®] trap, centered over, and extending beyond the packing material on side A. Re-connect the argon gas to side B of the Carbotrap[®] trap.

11.3.4 Open the argon stopcock, and allow gas to flow for 30 sec prior to heating the column. Make sure that the post GC pyrolytic column is on and red-hot (~700°C).

11.3.5 Apply power to the coil around the sample trap for 45 sec (using an automatic timer) to thermally desorb the ethylated species from the sample trap into the GC column.

11.3.6 Turn on the chart recorder or other data acquisition device to start data collection.

11.3.7 Three peaks should emerge during the analytical run. The first peak (~1 min) is Hg⁰, which is residual, and non-quantitative. This peak signifies the start of the peak set. Usually, the second peak to emerge (~2.5 min) is methylethyl mercury, the peak of interest. Following this (~4 min) is the peak for diethyl mercury ((CH₃CH₂)₂Hg), which is the ethylation product of Hg(II). If (CH₃)₂Hg were present in the sample, it would appear as a second peak between Hg⁰ and methylethyl mercury-not fully resolved from the Hg⁰. See appendix for advice on the quantitation of (CH₃)₂Hg.

- 11.3.8** Allow the GC run to proceed at least 1 min beyond the point that the diethyl mercury (Hg(II)) peak returns to base line. Place the next sample Carbotrap[®] trap in line and proceed with analysis of the next sample.
- 11.4** Peaks generated using this technique should be very sharp and almost symmetrical. Methyleneethyl mercury elutes at approximately 2.5 min and has a width at half-height of about 10 sec. Earlier peaks (Hg⁰, (CH₃)₂Hg) are sharper, while later peaks (diethyl mercury) are broader.
- 11.4.1** The appearance of only one peak (Hg⁰) usually signifies either that the pyrolytic column is not turned on, or that NaBEt₄ was not added to the sample.
- 11.4.2** Normally the Hg⁰ peak is quite small. However, some Hg⁰ is generated by thermal degradation of diethyl mercury during the desorption step. Thus, when samples contain a high concentration of Hg(II), both the Hg⁰ and the diethyl mercury peaks will be bigger. The ratio of the two peaks is indicative of the quality of the Carbotrap[®] trap. As the Carbotrap[®] trap degrades, the amount of thermal breakdown of organo-mercurials increases. Since the diethyl mercury is much more sensitive to thermal breakdown than the methyleneethyl mercury, monitoring the latter peak can serve as an early warning for Carbotrap[®] trap replacement. Generally, the Carbotrap[®] traps should be replaced any time the Hg⁰ peak grows to be as large as the diethyl mercury peak. As a rule of thumb for samples with significant Hg(II), use 1.0 ng Hg(II) from a non-acidified solution deliberately added to the reaction vessel as a trap check. For samples very low in Hg(II), such as blanks, the Hg⁰ peak is generally higher than the diethyl mercury peak, due to residual sources.
- 11.4.3** In the event that samples with large Hg(II) content are analyzed, some of the diethyl mercury generated breaks down to monoethyl mercury (CH₃CH₂Hg) during thermal desorption. If this occurs, a very broad peak (width of several minutes) will appear at some long time after the run is over (5-20 min). Such occurrences result in a confusing and messy increase and then decrease in the baseline. Such peaks can be hurried through the system by turning the GC column to 140°C until the peak emerges, and then reducing the temperature back to 110°C before resuming analysis.

12.0 Data Analysis and Calculations

- 12.1** Calculate the following parameters for each analytical batch:
- 12.1.1** Ethylation blank ($n = 1$) or the mean ethylation blank ($n > 1$)
- 12.1.2** Ethylation-blank subtracted calibration factor for each standard (Cf_x , Section 10.1.3) and peak measurement for each sample (R_s)
- 12.1.3** The mean calibration factor (Cf_m), standard deviation of the calibration factor (SD), and relative standard deviation (RSD) of the calibration factor (Section 10.1.1.4).
- 12.2** Compute the concentration of CH₃Hg in ng/L (parts-per-trillion; ppt) according to Equation 4:

Equation 4

$$[\text{CH}_3\text{Hg}](\text{ng} / \text{L}) = \frac{R_s - R_{\text{EB}}}{\text{CF}_m * V}$$

Where:

R_s =gross peak height (or area) of signal for CH_3Hg in sample

R_e =peak height (or area) of signal for CH_3Hg in ethylation blank ($n = 1$) or mean ethylation blank ($n > 1$)

CF_m =mean calibration factor

V =Sample volume (L)

-
- 12.3** The CH_3Hg concentration of the mean ($n=3$ or more) method blank (ng/L, Equation 4) should be subtracted from the sample concentration calculated above to obtain the net in situ CH_3Hg concentration (Equation 5).

Equation 5

$$[\text{CH}_3\text{Hg}]_{\text{MB}}(\text{ng} / \text{L}) = \frac{R_{\text{MB}} - R_{\text{EB}}}{\text{CF}_m * V_{\text{MB}}} * \frac{V_{\text{MB}}}{V_s}$$

where:

R_{MB} =gross peak height (or area) of signal for CH_3Hg in the mean method blank

R_{EB} =gross peak height (or area) of signal for CH_3Hg in the ethylation blank ($n = 1$) or the mean ethylation blank ($n > 1$)

CF_m =Mean calibration factor

V_{MB} =Volume of the method blank

V_s =Volume of the sample

Equation 6

$$[\text{CH}_3\text{Hg}]_{\text{net}} = [\text{CH}_3\text{Hg}]_{\text{sample}} - [\text{CH}_3\text{Hg}]_{\text{MB}}$$

where:

$[\text{CH}_3\text{Hg}]_{\text{net}}$ =net in situ CH_3Hg concentration (ng/L)

$[\text{CH}_3\text{Hg}]_{\text{sample}}$ =ethylation-blank corrected concentration of CH_3Hg in the sample (ng/L, Equation 3)

$[\text{CH}_3\text{Hg}]_{\text{MB}}$ =concentration of CH_3Hg in the mean method blank (ng/L, Equation 4)

12.4 Reporting

12.4.1 All results are reported after subtraction of mean method blanks (Equation 6).

12.4.2 Under the conditions described here, the distillation procedure not 100% efficient in recovering CH_3Hg because not all of the sample volume can be distilled, to avoid co-

distillation of HCl. Laboratories should calculate the efficiency of the distillation for their laboratory. This calculation is done by keeping a running mean of the last 30 recoveries calculated for precision and recovery samples (IPR and OPR), excluding all values that are more than two standard deviations from the mean. Since the distillation technique is inherently and reproducibly non-quantitative, all results should be recovery corrected by an empirically derived factor (Equation 7).

Equation 7

$$F = \frac{100}{R}$$

where:

F = Empirically derived correction factor

R = Recovery (the running mean of the last 30 IPR and OPR samples)

12.4.3 Report all values in ng/L to three significant figures. Report results below the ML as <0.06 ng/L, or as required by the permitting authority or in the permit. If the laboratory achieved an MDL lower than 0.02 ng/L (Section 1.5), a new ML may be calculated by multiplying the laboratory-determined MDL by 3.18 and rounding the result to the nearest multiple of 1, 2, 5, 10, etc. in accordance with procedures described in the EPA *Draft National Guidance for the Permitting, Monitoring, and Enforcement of Water Quality-Based Effluent Limitations Set Below Analytical Detection/Quantitation Levels*, March 22, 1994. Results below this level should be reported as less than the calculated ML.

13.0 Method Performance

13.1 The method detection limit (MDL) listed in Table 1 and the quality control acceptance criteria listed in Table 2 were validated in four laboratories. In addition, the techniques in this method have been intercompared with other techniques for low-level CH₃Hg determination in water in the International Mercury Speciation Intercomparison Exercise (Reference 15).

14.0 Pollution Prevention

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity or toxicity of waste at the point of generation. Many opportunities for pollution prevention exist in laboratory operation. EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option. The acids used in this method should be reused as practicable by purifying by electrochemical techniques. The only other chemicals used in this method are the neat materials used in preparing standards. These standards are used in extremely small amounts and pose little threat to the environment when managed properly. Standards should be prepared in volumes consistent with laboratory use to minimize the disposal of excess volumes of expired standards.

14.2 For information about pollution prevention that may be applied to laboratories and research institutions, consult *Less is Better: Laboratory Chemical Management for Waste Reduction*,

available from the American Chemical Society's Department of Governmental Relations and Science Policy, 1155 16th Street NW, Washington DC 20036, 202/872-4477.

15.0 Waste Management

- 15.1** The laboratory is responsible for complying with all federal, state, and local regulations governing waste management, particularly hazardous waste identification rules and land disposal restrictions, and for protecting the air, water, and land by minimizing and controlling all releases from fume hoods and bench operations. Compliance with all sewage discharge permits and regulations is also required.
- 15.2** Acids, samples at pH <2, and BrCl solutions must be neutralized before being disposed of, or must be handled as hazardous waste.
- 15.3** For further information on waste management, consult *The Waste Management Manual for Laboratory Personnel* and *Less is Better: Laboratory Chemical Management for Waste Reduction*, both available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th Street NW, Washington, DC 20036.

18.0 Glossary

The definitions and purposes below are specific to this method, but have been conformed to common usage as much as possible.

- 18.1** Ambient Water: Waters in the natural environment (e.g., rivers, lakes, streams, and other receiving waters), as opposed to effluent discharges.
- 18.2** Analytical Batch: A batch of up to 20 samples that are oxidized with the same batch of reagents and analyzed during the same 12-hour shift. Each analytical batch must also include an OPR and a QCS. MS/MSD samples must be prepared at a frequency of 10% per analytical batch (one MS/MSD for every 10 samples).
- 18.3** Intercomparison Study: An exercise in which samples are prepared and split by a reference laboratory, then analyzed by one or more testing laboratories and the reference laboratory. The intercomparison, with a reputable laboratory as the reference laboratory, serves as the best test of the precision and accuracy of the analyses at natural environmental levels.
- 18.4** Matrix Spike (MS) and Matrix Spike Duplicate (MSD): Aliquots of an environmental sample to which known quantities of the analyte(s) of interest is added in the laboratory. The MS and MSD are analyzed exactly like a sample. Their purpose is to quantify the bias and precision caused by the sample matrix. The background concentration(s) of the analyte(s) in the sample matrix must be determined in a separate aliquot and the measured values in the MS and MSD corrected for these background concentrations.
- 18.5** May: This action, activity, or procedural step is allowed but not required.
- 18.6** May not: This action, activity, or procedural step is prohibited.
- 18.7** Minimum Level (ML): The lowest level at which the entire analytical system must give a recognizable signal and acceptable calibration point for the analyte. It is equivalent to the concentration of the lowest calibration standard, assuming that all method-specified sample weights, volumes, and cleanup procedures have been employed. The ML is calculated by multiplying the MDL by 3.18 and rounding the result to the number nearest to $(1, 2, \text{ or } 5) \times 10^n$, where n is an integer.
- 18.8** Must: This action, activity, or procedural step is required.
- 18.9** Quality Control Sample (QCS): A sample containing CH_3Hg at known concentrations. The QCS is obtained from a source external to the laboratory, or is prepared from a source of standards different from the source of calibration standards. It is used as an independent check of instrument calibration.

- 18.10** Reagent Water: Prepared from 18 MΩ ultrapure deionized water starting from a prepurified source. Reagent water is used to wash bottles, as source water for trip and field blanks, and in the preparation of standards and reagents.
- 18.11** Sample set: Samples collected from the same site or, if for compliance monitoring, from a given discharge. This term applies to samples collected at the same time, to a maximum of ten samples.
- 18.12** Shall: This action, activity, or procedure is required.
- 18.13** Should: This action, activity, or procedure is suggested, but not required.
- 18.14** Stock Solution: A solution containing an analyte that is prepared from a reference material traceable to EPA, NIST, or a source that will attest to the purity and authenticity of the reference material.
- 18.15** Ultraclean Handling: A series of established procedures designed to ensure that samples are not contaminated for CH₃Hg during sample collection, storage, or analysis.

Appendix A :

Determination of Dimethyl Mercury

1.0 Scope and Application

- 1.1** This method is for determination of dimethyl mercury ((CH₃)₂Hg) in unfiltered water by direct purge and trap, isothermal GC separation, and CVAFS detection.
- 1.2** The method described in this appendix is not supportable by the full range of QC samples, so the method is to be considered for research purposes only.
- 1.3** The method described in this appendix is subsidiary to Method 1630 (Methyl Mercury in Aqueous Samples by Aqueous Phase Ethylation, Purge and Trap, and CVAFS). As such, only the major differences between the (CH₃)₂Hg method and the CH₃Hg method will be described.
- 1.4** This method is designed for the determination of in the range of 0.0002 to 0.1 ng/L, and may be extended to higher levels by selection of a smaller sample size.
- 1.5** Since no reagents are added to the sample, the MDL is not ethylation blank limited, but is only limited by the instrumental noise. With the Tekran analyzer, the MDL for a 1 L sample volume is approximately 0.0002 ng/L as Hg (based on 7 replicates of a 0.0015 ng/L solution).

2.0 Summary of Method Changes

- 2.1** The analysis is performed using fresh, unfiltered, unpreserved samples. To minimize analyte losses, all efforts must be extended to speed the time between sample collection and sample analysis, and to minimize the contact of the sample with the atmosphere prior to purging.
- 2.2** Samples should be purged and analyzed in the field, but if this is not possible, samples may be collected directly into headspace-free 1-L glass bottles with fluoropolymer-lined caps, and sent via express to the laboratory for analysis. If kept unpreserved, dark, and cool, the (CH₃)₂Hg present in the sample is found to be stable for up to 48 h from the time of collection.
- 2.3** Under no circumstances can plastic bottles of any kind (including fluoropolymer) be used for the collection of samples for the determination of (CH₃)₂Hg. The half-life of dissolved (CH₃)₂Hg in fluoropolymer bottles is only about 6 h.
- 2.4** The entire 1 L sample is purged directly onto a Carbotrap[®] trap, using N₂ at a flow rate of 300 mL/min for 30 min. A specially constructed 1 L bottle with 24/40 ground glass fitting and fritted bubbler cap must be utilized for this purpose. After purging, the trap must be dried with N₂ and analyzed within 6 h, as described in method 1630.

- 2.5** The analyzer set-up for $(\text{CH}_3)_2\text{Hg}$ is exactly as in Method 1630, with the exception that the GC oven must be set at 80°C rather than 110°C , to facilitate separation of Hg^0 from $(\text{CH}_3)_2\text{Hg}$.
- 2.6** Upon desorption of the Carbotrap[®] trap into the GC column, up to two peaks will appear. The first is usually Hg^0 , which appears at approximately 1.0 min. The second is $(\text{CH}_3)_2\text{Hg}$, which appears approximately at 1.5 min.

NOTE: *Because these peaks are so close to each other, and either one or the other, or neither may be present, it is imperative that an event marker be triggered to signal the start of the GC run, so that the peak may be positively identified by its retention time.*

- 2.7** Calibration is performed by spiking appropriate aliquots of a $(\text{CH}_3)_2\text{Hg}$ standard into the same volume of reagent water as the samples, and purging onto Carbotrap[®] traps. A good calibration range is from 1 to 100 pg as Hg.
- 2.8** The stock solution for $(\text{CH}_3)_2\text{Hg}$ is a 1.0 parts per million solution in methanol, custom prepared by Strem Chemical (Newburyport, MA). A working stock (1 ng/mL) is prepared by 1:1000 dilution of the stock solution with methanol. These solutions have been found to be stable for over 4 years, when kept refrigerated, and dark, in glass bottles.
- 2.9** The stock solution as supplied by Strem is only approximate in its concentration. To exactly calibrate the solution, an aliquot of the working stock equal to approximately 1 ng is spiked into a bubbler of pre-purged reagent water, and then purged onto a gold coated sand trap. The trap is analyzed for total Hg according to EPA Method 1631. In this case, total Hg purged onto the trap equals $(\text{CH}_3)_2\text{Hg}$. Pre-calibrated working standards of $(\text{CH}_3)_2\text{Hg}$ in methanol are available for purchase (Frontier Geosciences Inc., or equivalent).

3.0 QC Measures

- 3.1** Not all QC measures available for method 1630 are available for use with the $(\text{CH}_3)_2\text{Hg}$ technique.
- 3.1.1** For each set of samples (or batch of 20), three method blanks, and two MS/MSD pairs should be measured. Since $(\text{CH}_3)_2\text{Hg}$ is rarely detected in the environment, matrix spikes should be low (i.e., 1-5 pg), to assure the ability to measure near the MDL.
- 3.1.2** No certified reference materials (CRMs) or second source LCSWs are available for $(\text{CH}_3)_2\text{Hg}$.
- 3.2** No interferences have been observed for this method, although volatile organic compounds, as might be present in waste waters and effluents could diminish the observed $(\text{CH}_3)_2\text{Hg}$ signal by co-eluting, and quenching the atomic fluorescence.

- 3.3** Separate field samples should be collected for replicates, and matrix spikes, since once the sample is opened, $(\text{CH}_3)_2\text{Hg}$ will rapidly be lost from solution by diffusion to the air.
- 3.4** Samples must not be filtered prior to analysis, or $(\text{CH}_3)_2\text{Hg}$ will be lost to the air.
- 3.5** Samples must not be stored acidified, or $(\text{CH}_3)_2\text{Hg}$ will decompose to CH_3Hg . Samples may be acidified just prior to analysis, if Hg^0 and $(\text{CH}_3)_2\text{Hg}$ are to be both purged simultaneously (as in Method 1631 Appendix).
- 3.6** Samples should be kept out of light, or $(\text{CH}_3)_2\text{Hg}$ will decompose to CH_3Hg .
- 3.7** Samples must not be stored in plastic containers, or $(\text{CH}_3)_2\text{Hg}$ will rapidly be lost by diffusion into the plastic matrix.

4.0 Performance

- 4.1** This method is not often used, and so has not been rigorously tested. However, experience indicates that the following QC objectives can be met in ambient water samples, when using 1 L samples.

5.0 Tables

Table 1 Dimethyl Mercury Analysis Using Method 1630 Appendix: Lowest Water Quality Criterion, Method Detection Limit, and Minimum Level

Metal	Lowest Ambient Water Quality Criterion ¹	Method Detection Limit (MDL) and Minimum Level (ML)	
		MDL ⁽²⁾	ML ⁽³⁾
Dimethyl Mercury $((\text{CH}_3)_2\text{Hg})$	none	0.0002 ng/L	0.0006 ng/L

NOTES:

- Lowest of the freshwater, marine, and human health ambient water quality criteria promulgated by EPA for nine States and the District of Columbia at 40 *CFR* Part 136 on May 4, 1995 (60 *FR* 22229).
- Method Detection Limit as determined by the procedure in 40 *CFR* Part 136, Appendix B.
- Minimum Levels (ML).

Table 2 Quality Control Acceptance Criteria for Performance Tests In EPA Method 1630 Appendix

Metal	IPR (Section 9.2)	OPR (Section 9.5)	Method Blanks (Section 9.4)	MS/MSD ¹ (Section 9.3)	
	s	S	Max Mean	%R	RPD
CH ₃ Hg	79-121%	77-123%	< 0.0001 ng/L	75-125%	25%

NOTES:

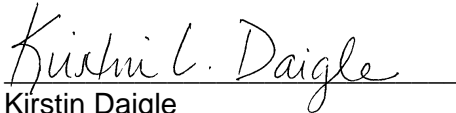

1. Recovery corrected.

Facility Distribution No. Electronic

Distributed To: Facility Intranet

The controlled copy of this SOP is the PDF copy of the SOP that is posted to the laboratory's SOP Directory. Printed copies of this SOP or electronic copies of this SOP distributed outside the facility are considered uncontrolled.

1.0 Scope and Application

This SOP describes the laboratory procedure used to determine the concentration of organotins in environmental samples using dual column gas chromatography with flame photometric detectors (GC/FPD).

1.1 Analytes, Matrices, and Reporting Limits

This procedure may be used for a variety of matrices including: water, soil, sediment, waste and tissue.

The list of target compounds that can be determined from this method along with the associated reporting limits (RL) is provided in Table 1.

2.0 Summary of Method

3 uL of extract is injected into a dual capillary column gas chromatograph equipped with flame photometric detectors (GC/FPD). Organotins are quantified using internal standard technique.

This procedure is a laboratory developed method derived from the NOAA Status and Trends Program Document: Sampling and Analytical Methods of the National Status and Trends Program, National Benthic Surveillance and Mussel Watch Projects 1984-1992, Vol. IV, NOAA Technical Memorandum, NOS ORCA 71.

3.0 Definitions

A list of terms and definitions are provided in Appendix A.

4.0 Interferences

- Method interference may be caused by contaminants in the extraction solvent. Solvents should be stored away from possible sources of contamination.
- Matrix interferences may be caused by contaminants co-extracted from the sample. The extent of the interferences will vary depending on the nature and diversity of the samples.
- Each lot of hexyl-magnesium bromide used during the extraction procedure for derivitization should be tested by the GC department prior to its use to ensure that it is free of contamination.

5.0 Safety

Employees must abide by the policies and procedures in the Corporate Environmental Health and Safety Manual (CW-E-M-001) and this document. This procedure may involve hazardous material, operations and equipment. This SOP does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of the method to follow appropriate safety, waste disposal and health practices under the assumption that all samples and reagents are potentially hazardous. Safety glasses, gloves, lab coats and closed-toe, nonabsorbent shoes are a minimum.

5.1 Specific Safety Concerns or Requirements

The gas chromatograph contains zones that have elevated temperatures. The analyst must be aware of the locations of those zones, and must cool them to room temperature prior to working on them.

There are areas of high voltage in the gas chromatograph. Depending on the type of work involved, either turn the power to the instrument off, or disconnect it from its source of power.

5.2 Primary Materials Used

Table 2 lists materials used in this method, which have a serious or significant hazard rating. **Note: This list does not include all materials used in the method. The table contains a summary of the primary hazards listed in the SDS for each of the materials listed in the table.** A complete list of materials used in the method can be found in the reagents and materials section. Employees must review the information in the SDS for each material before using it for the first time or when there are major changes to the SDS.

6.0 Equipment and Supplies

Catalog numbers listed in this SOP are subject to change at the discretion of the vendor. Analysts are cautioned to be sure equipment used meets the specification of this SOP.

6.1 Miscellaneous

- Autosampler Vials, National Scientific or equivalent.
- Volume limiting inserts
- Volumetric Syringes, Class "A" (10µl, 25µl, 50µl, 100µl, 250µl and 500µl), Hamilton or equivalent.

6.2 Analytical System

- Computer Hardware/Software: GC Acquisition Platform - ChemStation. Data Processing - Hewlett-Packard 9000-series computers, an HP 9000 K200 (Chemsvr5)/ HP-UX 10.20 and Chrom integrated with TALS.
- GC/FPD: with dual columns, dual FPDs, and auto-sampler capable of a 3-µl injection split onto two columns: HP 7673A, HP 7673A Autosampler.
- GC Columns: A dual fused silica capillary column system that will provide simultaneous primary and confirmation analyses:
 - RTX-35, (30m x 0.32 mmID x 0.25um)
 - RTX-5, (30m x 0.32 mmID x 0.25um)

Equivalent columns may be used, provided the elution orders are documented and compound separations are maintained.

7.0 Reagents and Standards

7.1 Reagents

- Hexane, Ultra-Resi Analyzed, JT Baker or equivalent.

7.2 Standards

Purchase stock standard solutions from commercial vendors and from these prepare calibration and working standards by diluting a known volume of stock standard in an appropriate solvent to the final volume needed to achieve the desired concentration. The extractions laboratory prepares all calibration standards, CCVs and ICVs. The recommended formulation for the standards used in this procedure is provided in the extraction SOP. The final concentration of each calibration level is provided in Appendix B of this SOP.

8.0 Sample Collection, Preservation, Shipment and Storage

The laboratory does not perform sample collection so these procedures are not included in this SOP. Sampling requirements may be found in the published reference method.

Listed below are the recommended sample amounts needed for analysis and size, preservation and holding time requirements:

Matrix	Sample Container	Recommended Sample Size	Preservation	Extract Holding Time ¹	Reference
Water	Glass	1 L	Chilled to 4°C (±2°C)	40 Days	Lab
Solid	Glass	50 g	Chilled to 4°C (±2°C)	40 Days	Lab
Tissue	Glass	50 g	-15°C (±5°C)	40 Days	Lab

¹Analytical holding time is determined from date of initiation of extraction.

Unless otherwise specified by client or regulatory program, after analysis, samples and extracts are retained for a minimum of 30 days after provision of the project report and then disposed of in accordance with applicable regulations.

9.0 Quality Control

9.1 Sample QC

The laboratory prepares the following quality control samples with each batch of samples.

QC Item	Frequency	Acceptance Criteria
Method Blank (MB)	1 in 20 or fewer samples	See Table 3
Laboratory Control Sample (LCS)	1 in 20 or fewer samples	See Table 3
Matrix Spike(s) MS/MSD	1 pair per extraction batch when sufficient sample volume is provided or per client request	See Table 3
Sample Duplicate (SD)	Client Request	See Table 3

9.2 Instrument QC

The following instrument QC is performed:

QC Item	Frequency	Acceptance Criteria
Initial Calibration (ICAL)	Initially; when ICV or CCV fail	See Table 3
Second Source Calibration Verification (ICV)	Once, after each ICAL	See Table 3
Continuing Calibration Verification (CCV)	Daily, every 10 samples, end of sequence	See Table 3
Retention Time Windows	As Needed	See Table 3

10.0 Procedure

10.1 Instrument Operating Conditions

Install a five meter deactivated guard column into the injection port and connect the guard column to the separate analytical columns using a glass "Y". The analytical columns are installed into independent FPD detectors.

The recommended instrument operating conditions are as follows:

Initial Temperature:	100°C for 2 minutes
Temperature Program:	20°C per minute to 290°C Hold for 1 minute.
Detector Temperature	300°C
Injector Temperature:	190°C
Injection volume:	3µL
Carrier Gas:	Helium flow set at 6.0-10.0 mL/min
Makeup Gas:	Hydrogen (supplied by tank) and zero air (supplied by gas generators) should be optimized for sensitivity, but is generally set at approximately 175 mL/min total flow

10.2 Retention Time Window Establishment

An RT window of ± 0.05 minutes is used. The center of the RT window is set at the midpoint calibration level in the initial calibration sequence.

10.3 Instrument Calibration

10.3.1 Initial Calibration (ICAL)

Before initial or daily calibration, inject at least one instrument blank (IBLK) consisting of 100 µL hexane and 10µL Internal standard to bring the GC/FPD system online. A conditioning of two more instrument blanks may be needed.

The instrument is calibrated using a minimum of five different concentration levels for each target analyte. The calibration standards are prepared and derivatized following the procedures given in the extraction SOP. Prepare calibration standards for analysis by adding 10 µL of internal standard (tetra-n-propyltin) to 100 µL of standard in an autosampler vial insert. Cap the vials and place on the autosampler tray. Enter the Chrom ID numbers into the acquisition software. Set

the autosampler to inject 3- μ l of each calibration standard. Start the acquisition process and autosampler.

The data processing system calculates the Response Factor (RF), mean RF and Percent Relative Standard Deviation (%RSD) for each analyte on both columns. The %RSD for each target analyte must be less than or equal to 20% in order to use the mean RF for quantification. If this criterion is not met, use another suitable quantification method for that analyte or correct the problem and repeat the calibration. Once a method of quantification is chosen for a specific compound, it must be consistent throughout the entire analytical sequence until a new initial calibration is performed.

Alternate Quantification Option:

Linear Regression & Weighted Linear Regression: Generate a curve of concentration vs. response for each analyte and calculate the correlation coefficient. The calibration must have a correlation coefficient ($r \geq 0.995$ (or $r^2 \geq 0.990$)). If this criterion is not met, correct the problem and repeat the calibration. The use of linear regression requires a minimum of 5 calibration points.

10.3.2 Second Source Calibration Verification (ICV)

Immediately after each calibration and prior to the analysis of QC or field samples, verify the accuracy of the initial calibration by analyzing a second source ICV.

The ICV is prepared and derivatized following the procedures given in the extraction SOP. Prepare the ICV for analysis by adding 10 μ L of internal standard (tetra-n-propyltin) to 100 μ L of ICV in an autosampler vial insert. Inject 3 μ l of the ICV standard onto the instrument in the same manner as performed for the initial calibration standards.

The percent recovery of each analyte must be within $\pm 25\%$ of the expected value (%R: 75 -125). If this criterion is not met, correct the problem and reanalyze the ICV. If the reanalysis fails, remake the calibration standards or ICV standard and/or perform instrument maintenance and recalibrate. The QC acceptance criteria must be met on both columns.

10.3.3 Continuing Calibration Verification (CCV)

CCVs are prepared and derivatized following the procedures given in the extraction SOP. Prepare CCVs for analysis by adding 10 μ L of internal standard (tetra-n-propyltin) to 100 μ L of CCV in an autosampler vial insert. Inject 3 μ l of the CCV standard onto the instrument in the same manner as performed for the initial calibration standards.

Analyze a CCV at or below mid-calibration level each day before sample analysis, after every ten injections and at the end of each analytical batch to monitor instrument drift. Calculate the RF and percent difference or drift (Appendix C) for each analyte on both columns. The percent difference or drift must be within $\pm 25\%$ for each analyte. Compare the RT of each analyte in the CCV with the established RT windows; the RT must be within the established window (refer to section 10.2). The acceptance criteria must be met on both columns.

If the CCV fails, it may be repeated once. If repeat analysis fails, corrective action must be taken. Samples must be bracketed by passing CCVs. Samples analyzed before and after CCV failure must be reanalyzed, unless the CCV is high and there are no detects in the associated samples.

10.4 Troubleshooting

Check the following items in case of calibration failures:

- ICAL Failure – Perform injection port maintenance, install new guard column, check detector ends to see if detector jet has slipped. In extreme cases, install new columns, particularly if the chromatography has degraded as evidenced by peak shapes.
- CCV Failure – Perform Injection port maintenance; if injection port maintenance does not restore CCV, install a new guard column and remove one or more loops from each analytical column.
- Needle crushed during injection - Replace the needle and check the injection port for obstructions and check the autosampler for misalignment.
- Auto-sampler failure - Reset the auto-sampler.
- Power failure - Reset run in ChemStation and re-acquire or re-initiate run sequence.

10.5 Sample Preparation

Remove the sample extract from refrigerated storage and warm to room temperature.

Prepare samples for analysis by adding 10 µL of internal standard (tetra-n-propyltin) to 100 µL of sample in an autosampler vial insert. Cap the vials and place on the autosampler tray. Enter the sample ID's into the data acquisition program.

10.6 Sample Analysis

Arrange the samples in a sequence that begins with the calibration standards and ICV followed by the analysis of QC samples, field samples and continuing calibration verification standards (CCVs).

Enter the standard and sample names into the data acquisition program in the order the samples were placed in the autosampler tray and initiate the analytical sequence. Set the autosampler to inject 3-µl of each standard and sample onto the instrument.

An example analytical sequence that includes initial calibration (ICAL) and subsequent sample analysis is provided below.

Injection Number	Lab Description
1-3	Instrument Blank
4	Level 1 Tin Standard
5	Level 2 Tin Standard
6	Level 3 Tin Standard
7	Level 4 Tin Standard
8	Level 5 Tin Standard
9	Instrument Blank
10	ICV
11 - 20	10 injections

21	CCV (250ppb Tin Standard)
	Repeat steps 9 -19

Cleaning blanks (IBLK) consisting of hexane may be analyzed after high-level samples at the discretion of the analyst.

11.0 Calculations / Data Reduction

11.1 Qualitative Identification

The data processing system identifies the target analytes by comparing the retention times of the peaks to the established retention time windows (refer to section 10.2).

Review and accept or reject the qualitative identifications made by the data processing software using the following guidelines:

Compare the retention times of the peaks to the established RT windows (refer to section 10.2), taking into account the shift of the surrogate peak. If the surrogate peak has shifted, open the retention time window in the direction of the shift. The processing software identifies the peak in the retention time window that is closest to the expected retention time set in the Chrom method, so the peak may need to be re-identified if a shift has occurred.

Look for shoulders on large peaks that may be the peaks of interest. The processing software does not always automatically integrate the shoulder off of the larger peak, so manual integration (split) of the shoulder may be necessary.

Each target analyte must be qualitatively detected on each column for identification to be confirmed.

11.2 Quantitative Identification

The data system calculates the corrected concentration for each target analyte from the calibration curve using the equations given in Appendix C. If sample interference is suspected, the laboratory may choose to report the value from the result that is not affected by interference. The lower value between the two columns is reported unless otherwise specified for the project.

11.3 Calculations

See Appendix C.

11.4 Data Review

11.4.1 Primary Review

Review project documents to ensure those project requirements were met. If project requirements were not met, immediately notify the project manager (PM) to determine an appropriate course of action.

Confirm qualitative and quantitative identification criteria using the criteria provided in Sections 11.1 and 11.2. If the data system does not properly integrate the peaks perform and document manual integration in accordance with laboratory SOP BR-QA-006.

Upload the data files from the data processing system to the laboratory information management system (TALS). Complete the batch information for standards and reagents and verify ICAL and QC sample associations. Review the results and set results to primary, secondary, acceptable or rejected as appropriate. Dilute and reanalyze samples whose results exceed the calibration range. The dilution analysis should result in a determination within the calibration range, preferably in the upper half of the calibration range. A more concentrated analysis is not necessary unless the project requires it. Dilution analyses may be performed to minimize matrix interference.

If a sample was analyzed immediately following a high concentration sample, review the results of the sample for any sign of carryover. If carryover is suspected, reanalyze the sample.

Create an NCM for any calibration, QC and sample data that is reported outside established acceptance criteria and/or schedule necessary corrective action. Set batch to 1st level review and complete the data review checklist.

Monobutyltin has been identified as a poor performing analyte in some matrices based on statistical data. Consequently corrective action will not be taken when LCS or MS/MSD recovery is not within established limits for this analyte. Initiate an NCM to document the exceedance and indicate poor performing analyte as the justification for not taking corrective action.

*Monobutyltin has poor extraction efficiency exhibiting a mean recovery of typically less than 5%. The low mean recovery is typical of routine implementation of this method. Although the laboratory has reported control limits of 10-48% for this analyte these control limits are not based on historical performance and do not indicate expected performance of this analyte by this method. The laboratory does not use the recovery or performance of this compound as a basis for acceptance of the analytical batch. All analytical results, both positive and *non-detects* are considered qualitative values.*

11.4.2 Secondary Data Review

Spot-check quantitative and qualitative identifications using the criteria provided in Section 11.1 and Section 11.2.

If manual integrations were performed:

- Review each manual integration to verify that the integration is consistent and compliant with the requirements specified in laboratory SOP BR-QA-006. If a problem is found, immediately consult with the primary analyst or notify the Technical Director or QA Manager.

Reintegration (by secondary data reviewers) should not be performed except in limited circumstances such as when the primary analyst who performed the initial integration is not available to correct any errors found during secondary review. If reintegration is performed, each integration performed by the secondary reviewer must be reviewed by a peer analyst or the department supervisor to verify the integration is consistent and compliant with the requirements specified in laboratory SOP BR-QA-006.

- Check to ensure an appropriate technical reason code is provided for each manual integration. Acceptable technical reason codes are provided in laboratory SOP BR-QA-006.

Verify that the performance criteria for the QC items listed in Table 1 were met. If the results do not fall within the established limits verify the recommended corrective actions were performed. Verify an NCM was initiated for any QC that does not meet established criteria and verify data is qualified accordingly. Set samples to 2nd level review.

Run the QC Checker, investigate and correct any problems found. Run and review the deliverable. Fix any problems found then set the method chain to lab complete.

11.5 Data Reporting

Data reporting and creation of the data deliverable is performed by the LIMS using the formatters set by the project manager during project initiation.

Analytical results above the reporting limit (RL) are reported as the value found. Analytical results less than the RL are reported as non-detect to the adjusted RL. The RL is adjusted for sample dilution/concentration. The unadjusted RL for each target analyte is provided in Section 1. If estimated values are requested by the project, results between the DL and the RL are reported and flagged as estimated.

Electronic and hardcopy data are maintained as described in laboratory SOP BR-QA-014 Laboratory Records.

12.0 Method Performance

12.1 Method Detection Limit Study (MDL)

Perform a method detection limit (MDL) study at initial method set-up following the procedures specified in laboratory SOP BR-QA-005.

12.2 Demonstration of Capabilities (DOC)

Perform a method demonstration of capability at initial set-up and when there is a significant change in instrumentation or procedure.

Each analyst that performs the analytical procedure must complete an initial demonstration of capability (IDOC) prior to independent analysis of client samples. Each analyst must demonstrate on-going proficiency (ODOC) annually thereafter. DOC procedures are further described in the laboratory's quality system manual (QAM) and in the laboratory SOP for employee training.

12.3 Training Requirements

Any employee that performs any portion of the procedure described in this SOP must have documentation in their employee training file that they have read this version of this SOP.

Instrument analysts, prior to independent analysis of client samples, must also have documentation of demonstration of initial proficiency (IDOC) and annual on-going proficiency (ODOC) in their employee training files.

13.0 Pollution Control

It is TestAmerica's policy to evaluate each method and look for opportunities to minimize waste generated (i.e., examine recycling options, ordering chemicals based on quantity needed, preparation of reagents based on anticipated usage and reagent stability). Employees must abide by the policies in Section 13 of the Corporate Safety Manual for "Waste Management and Pollution Prevention."

14.0 Waste Management

Waste management practices are conducted consistent with all applicable rules and regulations. Excess reagents, samples and method process wastes are disposed of in an accepted manner. Waste description rules and land disposal restrictions are followed. Waste disposal procedures are incorporated by reference to BR-EH-001. The following waste streams are produced when this method is carried out.

- Vials containing sample extracts: Satellite container: 15 gallon bucket connected to a fume hood.
- Solvent Waste: Satellite container: 1 L glass bottle located in fume hood.

Revision History

BR-GC-008, Rev. 11

- Title Page: Updated approval signatures and copyright date
- Section 6.1: Added value limiting inserts and removed Hydrogen generator
- Section 6.2: Updated GC/FPD hardware and autosampler. Updated software to ChemStation and Chrom.
- Section 10.1: Corrected Injector Temperature to 190°C.
- Section 10.3.1: Changed the number of blanks to at least 1, added internal standards and changed standard names to Chrom ID numbers.
- Section 10.6: Replaced ppb information with ICAL standard level references in the table.
- Appendix B: Updated tables.
- Updated MSDS to SDS

BR-GC-008, Rev. 10

- Incorporated CIPA: BR-GC-008, Rev. 9 into Rev. 10
- In section 10.1 revised time/temperature and flow rate for Instrument Operating Conditions
- In section 11.4.1 updated use of TALS and added statement indicating Monobutyltin as a poor performer.

BR-GC-008, Rev. 9

- SOP updated to the new TestAmerica format.
- Standard concentration tables were added to Appendix B.
- Formulas in Appendix C were revised to use Response Factors instead of Calibration Factors.
- Language was added to section 10.2 to allow for updating RT windows on CCVs.
- Language was added to section 11.4.1 to allow for dilution to minimize matrix interference.
- Added statement after table 1A indicating Monobutyltin as a poor performer.

Table 1: Routine Target Analyte List & Reporting Limit (RL)

ANALYTE	Routine Reporting Limit (RL) ^{1,2}	
	Water (ug/L)	Solid (ug/Kg)
Tetrabutyltin	0.050	1.7
Tributyltin	0.045	1.5
Dibutyltin	0.039	1.3
Monobutyltin ¹	0.62	20.7
Tripentyltin (Surrogate)	N/A	N/A

¹The routine RL is the unadjusted value that can be achieved in a blank matrix.

²The RL for tissue matrix is project defined.

Table 1A: Routine Accuracy and Precision Limits¹

Analyte	In-House Limits ² (%R)		Precision (RPD) (≤)
	Water	Solid	
Tetrabutyltin	30-150	30-160	30
Tributyltin	30-150	30-160	30
Dibutyltin	30-150	30-160	30
Monobutyltin ¹	10-48	10-48	30
Tripentyltin (Surrogate)	15-150	30-120	N/A

¹The control limits for Monobutyltin are advisory because this analyte is a poor performer.

Table 2: Primary Materials Used

Material ¹	Hazards	Exposure Limit ²	Signs and symptoms of exposure
Hexane	Flammable Irritant	500 ppm-TWA	Inhalation of vapors irritates the respiratory tract. Overexposure may cause lightheadedness, nausea, headache, and blurred vision. Vapors may cause irritation to the skin and eyes.

¹ Always add acid to water to prevent violent reactions.

² Exposure limit refers to the OSHA regulatory exposure limit.

Table 3: QC Summary, Frequency, Acceptance Criteria and Recommended Corrective Action

QC Item	Frequency	Acceptance Criteria	Recommended Corrective Action ¹
ICAL	Before sample analysis, when CCVs indicate calibration is no longer valid; after major instrument maintenance	Option 1: RSD for each analyte \leq 20% Option 2: Linear Regression: $r \geq$ 0.995	Correct problem, reanalyze, and repeat calibration.
ICV	After each initial calibration	(% R) \pm 25% from expected value	Correct problem and verify second source standard. If that fails, repeat initial calibration.
CCV	Daily before sample analysis, every 10 samples and at the end of the analytical sequence	% Difference or Drift \pm 25%	Re-analyze once, if still outside criteria perform corrective action, sequence can be re-started if two successive CCVs pass, otherwise repeat ICAL and all associated samples since last successful CCV, unless CCV is high and bracketed samples are non-detects.
MB	One per extraction batch of 20 or fewer samples	Target Analyte < RL	Examine project DQO's and take appropriate corrective action, which may include re-analysis of MB, re-extraction of batch, and/or non-conformance report (NCR). Corrective action must be documented on NCR. If there are no detects in samples, or if all detects are > 10 X MB level, re-prep and reanalysis may not be required.
LCS	One per extraction batch of 20 or fewer samples	See Table 1A	Examine project DQO's and take appropriate corrective action, which may include re-analysis of LCS, re-extraction of batch, and/or non-conformance report (NCR). Corrective action must be documented on NCR. Flag all reported values outside of control limits.
MS/MSD SD	MS/MSD: Per extraction batch SD: Per client request	See Table 1A	Evaluate data and determine if a matrix effect or analytical error is indicated. If analytical error, re-analyze and/or re-extract. Flag all reported values outside of control limits.
Surrogate	All field and QC samples	See Table 1A	Evaluate data and determine if a matrix effect or analytical error is indicated. If analytical error, re-analyze or re-extract. If matrix effect, review project DQOs to determine if a matrix effect must be confirmed by re-analysis. Flag all reported values outside of control limits.

¹The recommended corrective action may include some or all of the items listed in this column. The corrective action taken may be dependent on project data quality objectives and/or analyst judgment but must be sufficient to ensure that results will be valid. If corrective action is not taken or is not successful, data must be flagged with appropriate qualifiers.

Appendix A: Terms and Definitions

Acceptance Criteria: specified limits placed on characteristics of an item, process or service defined in requirement documents.

Accuracy: the degree of agreement between an observed value and an accepted reference value. Accuracy includes a combination of random error (precision) and systematic error (bias) components which are due to sampling and analytical operations; a data quality indicator.

Analyte: The specific chemicals or components for which a sample is analyzed. (EPA Risk Assessment Guide for Superfund, OSHA Glossary).

Batch: environmental samples that are prepared and/or analyzed together with the same process, using the same lot(s) of reagents. A preparation/digestion batch is composed of one to 20 environmental samples of similar matrix, meeting the above criteria. An analytical batch is composed of prepared environmental samples (extracts, digestates and concentrates), which are analyzed together as a group.

Calibration: a set of operations that establish, under specified conditions, the relationship between values of quantities indicated by a measuring instrument or measuring system, or values represented by a material measure or a reference material and the corresponding values realized by the standards.

Calibration Curve: the graphical relationship between the known values or a series of calibration standards and their instrument response.

Calibration Standard: A substance or reference used to calibrate an instrument.

Continuing Calibration Verification (CCV): a single or multi-parameter calibration standard used to verify the stability of the method over time. Usually from the same source as the calibration curve.

Corrective Action: the action taken to eliminate the cause of an existing nonconformity, defect or other undesirable occurrence in order to prevent recurrence.

Data Qualifier: a letter designation or symbol appended to an analytical result used to convey information to the data user. (Laboratory)

Demonstration of Capability (DOC): procedure to establish the ability to generate acceptable accuracy and precision.

Holding Time: the maximum time that a sample may be held before preparation and/or analysis as promulgated by regulation or as specified in a test method.

Initial Calibration: analysis of analytical standards for a series of different specified concentrations used to define the quantitative response, linearity and dynamic range of the instrument to target analytes.

Internal Standard: a known amount of standard added to a test portion of a sample as a reference for evaluating and controlling the precision and bias of the applied analytical method.

Intermediate Standard: a solution made from one or more stock standards at a concentration between the stock and working standard. Intermediate standards may be certified stock standard solutions purchased from a vendor and are also known as secondary standards.

Laboratory Control Sample (LCS): a blank matrix spiked with a known amount of analyte(s) processed simultaneously with and under the same conditions as samples through all steps of the procedure.

Matrix Spike (MS): a field sample to which a known amount of target analyte(s) is added.

Matrix Spike Duplicate (MSD): a second replicate matrix spike

Method Blank (MB): a blank matrix processed simultaneously with and under the same conditions as samples through all steps of the procedure. Also known as the preparation blank (PB).

Method Detection Limit (MDL): the minimum amount of a substance that can be measured with a specified degree of confidence that the amount is greater than zero using a specific measurement system. The MDL is a statistical estimation at a specified confidence interval of the concentration at which relative uncertainty is $\pm 100\%$. The MDL represents a range where qualitative detection occurs. Quantitative results are only produced in this range and qualified with the proper data reporting flag when a project requires this type of data reporting.

Non-conformance: an indication, judgment, or state of not having met the requirements of the relevant specification, contract or regulation.

Precision: the degree to which a set of observations or measurements of the same property, obtained under similar conditions, conform to them.

Preservation: refrigeration and/or reagents added at the time of sample collection to maintain the chemical, physical, and/or biological integrity of the sample.

Quality Control Sample (QC): a sample used to assess the performance of all or a portion of the measurement system.

Reporting Limit (RL): the level to which data is reported for a specific test method and/or sample.

Stock Standard: a solution made with one or more neat standards usually with a high concentration. Also known as a primary standard. Stock standards may be certified solutions purchased from a vendor.

Surrogate: a substance with properties that mimic the analyte of interest but that are unlikely to be found in environmental samples.

Appendix B: Standard Preparation Tables

The standard formulations contained in this Appendix are recommended and are subject to change. If the concentration of the stock standard is different than those noted in this table, adjust the standard preparation formulation accordingly. Unless otherwise specified, prepare the standard solutions in hexane using Class A volumetric glassware and Hamilton syringes. Unless otherwise specified for a standard solution, assign an expiration date of 6 months from date of preparation unless the parent standard expires sooner in which case use the earliest expiration date. See laboratory SOP BR-QA-002 *Standard Preparation* for further guidance.

Internal standard (tetra-n-propyltin) is added to each calibration, ICV, CCV, and sample aliquot before analysis. 10 uL of internal standard is added to 100 uL of standard or sample aliquot for analysis.

Internal Standard Solution (5 mg/L)

Parent Standard	Vendor	Stock Standard Concentration (mg/L)	Volume Added (mL)	Final Volume (mL)	Final Concentration (mg/L)
Tetra-n-propyltin	Retek #31474	2000	0.100	40	5.0

All working calibration standards, ICVs and CCVs for this method are prepared and derivitized by the organic prep department following the procedures given in the extraction SOP.

Final Concentration of Prepared Calibration Standards (as alkyltin chloride compounds)

Component	Level 1 (ug/L)	Level 2 (ug/L)	Level 3 (ug/L)	Level 4 (ug/L)	Level 5 (ug/L)	ICV (ug/L)
Tripentyltin Chloride	50	100	250	500	1000	250
Tetrabutyltin	50	100	250	500	1000	250
Tributyltin chloride	50	100	250	500	1000	250
Dibutyltin dichloride	50	100	250	500	1000	250
Monobutyltin trichloride	100	200	500	1000	2000	500

Final Concentration of Prepared Calibration Standards (as un-substituted alkyltin compounds)

Component	Level 1 (ug/L)	Level 2 (ug/L)	Level 3 (ug/L)	Level 4 (ug/L)	Level 5 (ug/L)	ICV (ug/L)
Tripentyltin	45.0	90.0	225	450	900	225
Tetrabutyltin	50.0	100	250	500	1000	250
Tributyltin	44.5	89.0	222.5	445	890	222.5
Dibutyltin	38.5	77.0	192.5	385	770	192.5
Monobutyltin	62.0	124.0	310	620	1240	310

The alkyltin chloride compounds are reported as un-substituted alkyltin compounds. The factors used to convert from the alkyl tin chloride to the alkyl tin are listed below.

Analyte	Conversion Factor	Report as
Tetrabutyltin	---	Tetrabutyltin

Analyte	Conversion Factor	Report as
Tributyltin chloride	0.89	Tributyltin
Dibutyltin dichloride	0.77	Dibutyltin
Monobutyltin trichloride	0.62	Monobutyltin
Tripentyltin chloride (SS)	0.90	Tripentyltin
Tetrapropyltin (ISTD)	--	Tetrapropyltin

Conversion Factors are determined from the following formula:

$$\text{Conversion Factor} = \frac{MWT - MWC}{MWT}$$

MWT= Total molecular weight of the analyte

MWC= Number of chlorides * molecular weight of chloride (molecular weight of chloride = 35.5)

Appendix C: Equations

$$\text{Response Factor (RFx)} = \frac{\text{Peak area or height (x)} \times \text{Concentration (is)}}{\text{Peak area or height (is)} \times \text{Concentration (x)}}$$

Where: x=compound, is = Internal Standard

$$\text{Mean Response Factor } (\overline{\text{RF}}) = \frac{\sum_{i=1}^n \text{RF}_i}{n}$$

where: n = number of calibration levels

$$\text{Standard Deviation of the Response Factor (SD)} = \sqrt{\frac{\sum_{i=1}^n (\text{RF}_i - \overline{\text{RF}})^2}{n-1}}$$

where: n = number of calibration levels

Percent Relative Standard Deviation (RSD) of the Response Factor =

$$7 \frac{\text{SD}}{\overline{\text{RF}}} \times 100\%$$

$$\text{Percent Difference (\%D)} = \frac{\text{RF}_v - \overline{\text{RF}}}{\overline{\text{RF}}} \times 100\%$$

where: RF_v = Response Factor from the Continuing Calibration Verification (CCV)

Percent Drift = $\frac{\text{Calculated Concentration} - \text{Theoretical Concentration}}{\text{Theoretical Concentration}} \times 100\%$

$$\text{Percent Recovery (\%R)} = \frac{C_s}{C_n} \times 100\%$$

where: C_s = Measured concentration of the Spiked Field or QC Sample
C_n = Nominal Concentration of Spike Added

$$\text{Percent Recovery (\%R) for MS/MSD} = \frac{C_s - C_u}{C_n} \times 100\%$$

where: C_s = Measured concentration of the Spiked Sample
C_u = Measured concentration of the Unspiked Sample
C_n = Nominal Concentration of Spike Added

$$\text{Relative Percent Difference (RPD)} = \frac{|C_1 - C_2|}{\left(\frac{C_1 + C_2}{2}\right)} \times 100\%$$

where: C_1 = Measured Concentration of First Sample
 C_2 = Measured Concentration of Second Sample

Sample Concentration

Extract

$$C_{\text{extract}} (\text{ug/L}) = \frac{\text{Peak response (x)}}{\text{Peak response (is)}} \times \frac{\text{Concentration (is)}}{\text{Average RF (x)}}$$

Where: x=compound, is = Internal Standard

Water

$$C_{\text{sample}} (\text{ug/L}) = C_{\text{extract}} (\text{ug/L}) \times \frac{\text{extract volume (L)}}{\text{sample volume (L)}} \times DF$$

Solid

$$C_{\text{sample}} (\text{ug/Kg}) = C_{\text{extract}} (\text{ug/L}) \times \frac{\text{extract volume (L)}}{\text{sample weight (Kg)}} \times \frac{100}{\% \text{ solids}} \times DF$$

No. L-7

Chlorinated Herbicides

SW-846 Method 8151A

METHOD 8151A

CHLORINATED HERBICIDES BY GC USING METHYLATION OR PENTAFLUOROBENZYLATION DERIVATIZATION

1.0 SCOPE AND APPLICATION

1.1 Method 8151 is a capillary gas chromatographic (GC) method for determining certain chlorinated acid herbicides and related compounds in aqueous, soil and waste matrices. Specifically, Method 8151 may be used to determine the following compounds:

Compound	CAS No. ^a
2,4-D	94-75-7
2,4-DB	94-82-6
2,4,5-TP (Silvex)	93-72-1
2,4,5-T	93-76-5
Dalapon	75-99-0
Dicamba	1918-00-9
Dichloroprop	120-36-5
Dinoseb	88-85-7
MCPA	94-74-6
MCPP	93-65-2
4-Nitrophenol	100-02-1
Pentachlorophenol	87-86-5

^a Chemical Abstract Service Registry Number

1.2 Because these compounds are produced and used in various forms (i.e., acid, salt, ester, etc.), Method 8151 describes a hydrolysis step that can be used to convert herbicide esters into the acid form prior to analysis. Herbicide esters generally have a half-life of less than one week in soil.

1.3 When Method 8151 is used to analyze unfamiliar samples, compound identifications should be supported by at least one additional qualitative technique. Sec. 8.4 provides gas chromatograph/mass spectrometer (GC/MS) criteria appropriate for the qualitative confirmation of compound identifications.

1.4 The estimated detection limits for each of the compounds in aqueous and soil matrices are listed in Table 1. The detection limits for a specific waste sample may differ from those listed, depending upon the nature of the interferences and the sample matrix.

1.5 The following compounds may also be determined using this method:

Compound	CAS No. ^a
Acifluorfen	50594-66-6
Bentazon	25057-89-0
Chloramben	133-90-4
DCPA diacid ^b	2136-79-0
3,5-Dichlorobenzoic acid	51-36-5
5-Hydroxydicamba	7600-50-2
Picloram	1918-02-1

^a Chemical Abstract Service Registry Number

^b DCPA monoacid and diacid metabolites included in method scope; DCPA diacid metabolite used for validation studies. DCPA is a dimethyl ester.

1.6 This method is restricted to use by or under the supervision of analysts experienced in the use of gas chromatography and skilled in the interpretation of gas chromatograms. Each analyst must demonstrate the ability to generate acceptable results with this method.

1.7 Only experienced analysts should be allowed to work with diazomethane due to the potential hazards associated with its use (explosive, carcinogenic).

2.0 SUMMARY OF METHOD

2.1 Method 8151 provides extraction, derivatization, and gas chromatographic conditions for the analysis of chlorinated acid herbicides in water, soil, and waste samples. An option for the hydrolysis of esters is also described.

2.2 Water samples are extracted with diethyl ether and then esterified with either diazomethane or pentafluorobenzyl bromide. The derivatives are determined by gas chromatography with an electron capture detector (GC/ECD). The results are reported as acid equivalents.

2.3 Soil and waste samples are extracted and esterified with either diazomethane or pentafluorobenzyl bromide. The derivatives are determined by gas chromatography with an electron capture detector (GC/ECD). The results are reported as acid equivalents.

2.4 If herbicide esters are to be determined using this method, hydrolysis conditions for the esters in water and soil extracts are described.

2.5 The sensitivity of Method 8151 depends on the level of interferences in addition to instrumental limitations. Table 1 lists the GC/ECD and GC/MS detection limits that can be obtained in aqueous and soil matrices in the absence of interferences. Detection limits for a typical waste sample should be higher.

3.0 INTERFERENCES

3.1 Refer to Method 8000.

3.2 Method interferences may be caused by contaminants in solvents, reagents, glassware, and other sample processing hardware that lead to discrete artifacts or elevated baselines in gas chromatograms. All these materials must be routinely demonstrated to be free from interferences under the conditions of the analysis, by analyzing reagent blanks.

3.2.1 Glassware must be scrupulously cleaned. Clean each piece of glassware as soon as possible after use by rinsing it with the last solvent used in it. This should be followed by detergent washing with hot water and rinses with tap water, then with organic-free reagent water. Glassware should be solvent-rinsed with acetone and pesticide-quality hexane. After rinsing and drying, glassware should be sealed and stored in a clean environment to prevent any accumulation of dust or other contaminants. Store glassware inverted or capped with aluminum foil. Immediately prior to use, glassware should be rinsed with the next solvent to be used.

3.2.2 The use of high purity reagents and solvents helps to minimize interference problems. Purification of solvents by distillation in all-glass systems may be required.

3.3 Matrix interferences may be caused by contaminants that are coextracted from the sample. The extent of matrix interferences will vary considerably from waste to waste, depending upon the nature and diversity of the waste being sampled.

3.4 Organic acids, especially chlorinated acids, cause the most direct interference with the determination by methylation. Phenols, including chlorophenols, may also interfere with this procedure. The determination using pentafluorobenzoylation is more sensitive, and more prone to interferences from the presence of organic acids or phenols than by methylation.

3.5 Alkaline hydrolysis and subsequent extraction of the basic solution removes many chlorinated hydrocarbons and phthalate esters that might otherwise interfere with the electron capture analysis. However, hydrolysis may result in the loss of dinoseb and the formation of aldol condensation products if any residual acetone remains from the extraction of solids.

3.6 The herbicides, being strong organic acids, react readily with alkaline substances and may be lost during analysis. Therefore, glassware must be acid-rinsed and then rinsed to constant pH with organic-free reagent water. Sodium sulfate must be acidified.

3.7 Sample extracts should be dry prior to methylation or else poor recoveries will be obtained.

4.0 APPARATUS AND MATERIALS

4.1 Gas chromatograph - Analytical system complete with gas chromatograph suitable for Grob-type injection using capillary columns, and all required accessories including detector, capillary analytical columns, recorder, gases, and syringes. A data system for measuring peak heights and/or peak areas is recommended.

4.2 GC columns

The analyst may choose either narrow-bore or wide-bore GC columns. Narrow-bore column 1a is useful for GC/MS confirmation of these analytes. When using an electron capture detector, analyses two columns are necessary to provide confirmation of identifications.

Although not specifically evaluated under the chromatographic conditions described in this procedure, the analyst may opt to configure the GC for simultaneous dual-column operation using commercially-available Y-adapters to connect both columns to a single injector port and employing a separate electron capture detector for each column.

4.2.1 Narrow-bore columns

4.1.2.1 Primary column 1 - 30 m x 0.25 mm, 5% phenyl/95% methyl silicone (DB-5, J&W Scientific, or equivalent), 0.25 μm film thickness.

4.1.2.2 Primary column 1a (GC/MS) - 30 m x 0.32 mm, 5% phenyl/95% methyl silicone, (DB-5, J&W Scientific, or equivalent), 1 μm film thickness.

4.1.2.3 Column 2 - 30 m x 0.25 mm, 35% phenyl methylpolysiloxane (DB-608, J&W Scientific or equivalent), a 0.25 μm film thickness.

4.1.2.4 Confirmation column - 30 m x 0.25 mm, 14% cyanopropyl phenyl silicone, (DB-1701, J&W Scientific, or equivalent), 0.25 μm film thickness.

4.2.2 Wide-bore columns

4.2.2.1 Primary Column - 30 m x 0.53 mm DB-608 (J&W Scientific or equivalent) with 0.83 μm film thickness.

4.2.2.2 Confirmation Column - 30 m x 0.53 mm, 14% cyanopropyl phenyl silicone, (DB-1701, J&W Scientific, or equivalent), 1.0 μm film thickness.

4.3 Electron capture detector (ECD).

4.4 Kuderna-Danish (K-D) apparatus.

4.4.1 Concentrator tube - 10-mL graduated (Kontes K-570050-1025 or equivalent). A ground-glass stopper is used to prevent evaporation of extracts.

4.4.2 Evaporation flask - 500-mL (Kontes K-570001-500 or equivalent). Attach to concentrator tube with springs, clamps, or equivalent.

4.4.3 Snyder column - Three-ball macro (Kontes K-503000-0121 or equivalent).

4.4.4 Snyder column - Two-ball micro (Kontes K-569001-0219 or equivalent).

4.4.5 Springs - 1/2 inch (Kontes K-662750 or equivalent).

NOTE: The following glassware is recommended for the purpose of solvent recovery during the concentration procedures requiring the use of Kuderna-Danish evaporative concentrators. Incorporation of this apparatus may be required

by State or local municipality regulations that govern air emissions of volatile organics. EPA recommends the incorporation of this type of reclamation system as a method to implement an emissions reduction program. Solvent recovery is a means to conform with waste minimization and pollution prevention initiatives.

4.4.6 Solvent vapor recovery system (Kontes K-545000-1006 or K-547300-0000, Ace Glass 6614-30, or equivalent).

4.5 Diazomethane generator - Refer to Sec. 7.5 to determine which method of diazomethane generation should be used for a particular generation.

4.5.1 Diazald kit - Recommended for the generation of diazomethane (Aldrich Chemical Co., Catalog No. 210,025-0, or equivalent).

4.5.2 As an alternative, assemble from two 20 mm x 150 mm test tubes, two Neoprene rubber stoppers, and a source of nitrogen. Use Neoprene rubber stoppers with holes drilled in them to accommodate glass delivery tubes. The exit tube must be drawn to a point to bubble diazomethane through the sample extract. The generator assembly is shown in Figure 1. The procedure for use of this type of generator is given in Sec. 7.5.

4.6 Beaker - 400-mL, thick-walled.

4.7 Funnel - 75 mm diameter.

4.8 Separatory funnel - 500-mL, with polytetrafluoroethylene (PTFE) stopcock.

4.9 Centrifuge bottle - 500-mL, Pyrex® 1260 or equivalent.

4.10 Erlenmeyer flasks - 250-mL and 500-mL, with a ground-glass joint at the neck.

4.11 Pipet - Pasteur, glass, disposable (140 mm x 5 mm ID).

4.12 Vials - 10-mL, glass, with PTFE-lined screw-caps.

4.13 Volumetric flasks, Class A - 10-mL to 1000-mL.

4.14 Filter paper - 15 cm diameter (Whatman No. 1 or equivalent).

4.15 Glass wool - Pyrex®, acid washed.

4.16 Boiling chips - Solvent-extracted with methylene chloride, approximately 10/40 mesh (silicon carbide or equivalent).

4.17 Water bath - Heated, with concentric ring cover, capable of temperature control ($\pm 2^{\circ}\text{C}$). The bath should be used in a hood.

4.18 Balance - Analytical, capable of accurately weighing to 0.0001 g.

4.19 Centrifuge.

4.20 Ultrasonic extraction system - A horn-type device equipped with a titanium tip, or a device that will give equivalent performance, should be used. The disrupter must have a minimum power wattage of 300 watts, with pulsing capability. A device designed to reduce the cavitation sound is recommended. Follow the manufacturer's instructions for preparing the disrupter for extraction of samples. Use a 3/4" horn for most samples.

4.21 Sonobox - Recommended with above disrupters for decreasing cavitation sound (Heat Systems - Ultrasonics, Inc., Model 432B or equivalent).

4.22 pH paper - wide range

4.23 Silica gel cleanup column (Bond Elut™ - Analytichem, Harbor City, CA or equivalent).

4.24 Microsyringe - 10- μ L.

4.25 Wrist shaker - Burrell Model 75 or equivalent.

4.26 Drying column - 400 mm x 20 mm ID Pyrex® chromatographic column with Pyrex® glass wool at bottom and a PTFE stopcock.

NOTE: Fritted glass discs are difficult to decontaminate after highly contaminated extracts have been passed through. Columns without frits may be purchased. Use a small pad of Pyrex® glass wool to retain the adsorbent. Prewash the glass wool pad with 50 mL of acetone followed by 50 mL of elution solvent prior to packing the column with adsorbent.

5.0 REAGENTS

5.1 Reagent grade inorganic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 Organic-free reagent water. All references to water in this method refer to organic-free water, as defined in Chapter One.

5.3 Sodium hydroxide solution (0.1 N), NaOH - Dissolve 4 g of NaOH in organic-free reagent water and dilute to 1.0 L.

5.4 Potassium hydroxide solution (37% aqueous solution (w/v)), KOH - Dissolve 37 g of potassium hydroxide pellets in organic-free reagent water and dilute to 100 mL.

5.5 Phosphate buffer (0.1 M), pH = 2.5 - Dissolve 12 g sodium phosphate (NaH_2PO_4) in organic-free reagent water and dilute to 1.0 L. Add phosphoric acid to adjust the pH to 2.5.

5.6 N-methyl-N-nitroso-p-toluenesulfonamide (Diazald) - High purity (Aldrich Chemical Co., or equivalent).

5.7 Silicic acid, H_2SiO_5 - 100-mesh powder, store at 130°C.

5.8 Potassium carbonate, K_2CO_3 .

5.9 2,3,4,5,6-Pentafluorobenzyl bromide (PFBBR), $C_6F_5CH_2Br$ - Pesticide quality or equivalent.

5.10 Sodium sulfate (granular, acidified, anhydrous), Na_2SO_4 - Purify by heating at 400°C for 4 hours in a shallow tray, or by precleaning the sodium sulfate with methylene chloride. If the sodium sulfate is precleaned with methylene chloride, a method blank must be analyzed, demonstrating that there is no interference from the sodium sulfate. Acidify by slurring 100 g sodium sulfate with enough diethyl ether to just cover the solid; then add 0.1 mL of concentrated sulfuric acid and mix thoroughly. Remove the ether under vacuum. Mix 1 g of the resulting solid with 5 mL of organic-free reagent water and measure the pH of the mixture. It must be below a pH of 4. Store the remaining solid at 130°C.

5.11 Solvents - All solvents should be pesticide quality or equivalent.

5.11.1 Methylene chloride, CH_2Cl_2 .

5.11.2 Acetone, CH_3COCH_3 .

5.11.3 Methanol, CH_3OH .

5.11.4 Toluene, $C_6H_5CH_3$.

5.11.5 Diethyl Ether, $C_2H_5OC_2H_5$. Must be free of peroxides as indicated by test strips (EM Quant, or equivalent). Procedures for removal of peroxides are provided with the test strips.

NOTE: Diethyl ether used for this procedure should be stabilized with BHT, not with ethanol, as when ethanol-stabilized ether is used, the methylation reaction may not proceed efficiently, leading to low recoveries of target analytes.

5.11.6 Isooctane, $(CH_3)_3CH_2CH(CH_3)_2$.

5.11.7 Hexane, C_6H_{14} .

5.11.8 Carbitol (diethylene glycol monoethyl ether), $C_2H_5OCH_2CH_2OCH_2CH_2O$ - optional, for producing alcohol-free diazomethane.

5.12 Stock standard solutions (1000 mg/L) - May be prepared from pure standard materials or purchased as certified solutions.

5.12.1 Prepare stock standard solutions by accurately weighing about 0.010 g of pure acid. Dissolve the material in pesticide quality acetone and dilute to volume in a 10-mL volumetric flask. Stocks prepared from pure methyl esters are dissolved in 10% acetone/isooctane (v/v). Larger volumes may be used at the convenience of the analyst. If compound purity is certified at 96% or greater, the weight may be used without correction to calculate the concentration of the stock standard.

5.12.2 Transfer the stock standard solutions to vials with PTFE-lined screw-caps. Store at 4°C, protected from light. Stock standard solutions should be checked frequently for signs of degradation or evaporation, especially immediately prior to preparing calibration standards from them.

5.12.3 Stock standard solutions of the derivatized acids must be replaced after 1 year, or sooner, if comparison with check standards indicates a problem. Stock standard solutions of the free acids degrade more quickly and should be replaced after two months, or sooner if comparison with check standards indicates a problem.

5.13 Internal Standard Spiking Solution (if internal standard calibration is used) - To use this approach, the analyst must select one or more internal standards that are similar in analytical behavior to the compounds of interest. The analyst must further demonstrate that the measurement of the internal standard is not affected by method or matrix interferences.

5.13.1 The compound 4,4'-dibromooctafluorobiphenyl (DBOB) has been shown to be an effective internal standard, but other compounds, such as 1,4-dichlorobenzene, may be used if there is a DBOB interference.

5.13.2 Prepare an internal standard spiking solution by accurately weighing approximately 0.0025 g of pure DBOB. Dissolve the DBOB in acetone and dilute to volume in a 10 mL volumetric flask. Transfer the internal standard spiking solution to a vial with a PTFE-lined screw-cap, and store at room temperature. Addition of 10 μ L of the internal standard spiking solution to 10 mL of sample extract results in a final internal standard concentration of 0.25 μ g/L. The solution should be replaced if there is a change in internal standard response greater than 20 percent of the original response recorded.

5.14 Calibration standards - Prepare a minimum of five different concentrations for each parameter of interest, through dilution of the stock standards with diethyl ether or hexane. One of the standards should be at a concentration near, but above, the method detection limit. The remaining standards should correspond to the expected range of concentrations found in real samples or should define the working range of the GC. Calibration solutions must be replaced after six months, or sooner if comparison with check standards indicates a problem.

5.14.1 Derivatize each calibration standard prepared from free acids in a 10-mL K-D concentrator tube, according to the procedures beginning at Sec. 7.5.

5.14.2 Add a known, constant, amount of one or more internal standards to each derivatized calibration standard, and dilute to volume with the solvent indicated in the derivative option used.

5.15 Surrogate standards - The analyst should monitor the performance of the extraction, cleanup (when used), and determinative step, and the effectiveness of the method in dealing with each sample matrix, by spiking each sample, standard, and blank with one or two herbicide surrogates (e.g., herbicides that are not expected to be present in the sample) recommended to encompass the range of the temperature program used in this method. Deuterated analogs of analytes should not be used as surrogates in gas chromatographic analysis due to coelution problems.

5.15.1 The recommended surrogate is 2,4-Dichlorophenylacetic acid (DCAA).

5.15.2 Prepare a surrogate spiking solution by accurately weighing approximately 0.001 g of pure DCAA. Dissolve the DCAA in acetone, and dilute to volume in a 10-mL volumetric flask. Transfer the surrogate spiking solution to a vial with a PTFE-lined screw-cap, and store at room temperature. Addition of 50 μ L of the surrogate spiking solution to 1 L of sample, prior to extraction, results in a final concentration in the extract of 0.5 mg/L.

5.16 pH Adjustment Solutions

5.16.1 Sodium hydroxide, NaOH, 6 N.

5.16.2 Sulfuric acid, H₂SO₄, 12 N.

6.0 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.1 See the introductory material to this chapter, Organic Analytes, Sec. 4.1. One-Liter samples should be collected.

6.2 Extracts must be stored under refrigeration (4°C) and protected from light.

7.0 PROCEDURE

7.1 Extraction and hydrolysis of high concentration waste samples

7.1.1 Follow Method 3580, Waste Dilution, with the following exceptions:

7.1.1.1 Use diethyl ether as the dilution solvent.

7.1.1.2 Use acidified anhydrous sodium sulfate and acidified glass wool.

7.1.1.3 Spike the sample with surrogate(s) according to Sec. 5.15.

7.1.2 If the sample is to be analyzed for both herbicide esters and acids, then the sample extract must be hydrolyzed. In this case, transfer 1.0 mL (a smaller volume or a dilution may be required if herbicide concentrations are large) to a 250-mL Erlenmeyer flask with a ground-glass joint at the neck. Proceed to Sec. 7.2.3. If the analysis is for acid herbicides only, proceed to Sec. 7.5 for derivatization by diazomethane (if PFB derivatization is selected, reduce the volume of diethyl ether to 0.1 -0.5 mL as per Sec. 7.2 and then dilute to 4 mL with acetone).

7.2 Extraction and hydrolysis of soil, sediment, and other solid samples

Two extraction procedures are applicable to solid samples: ultrasonic extraction and shaker extraction. The same hydrolysis procedures (Sec. 7.2.3) apply to both types of extracts.

7.2.1 Ultrasonic extraction

7.2.1.1 Add 30 g (dry weight) of the well-mixed solid sample to a 400-mL thick-wall beaker. Adjust the pH to 2 with concentrated hydrochloric acid or acidify solids in the beaker with 85 mL of 0.1 M phosphate buffer (pH = 2.5) and thoroughly mix the contents with a glass stirring rod. Spike the sample with surrogate(s) (Sec. 5.15).

7.2.1.2 The ultrasonic extraction of solids must be optimized for each type of sample. In order for the ultrasonic extractor to efficiently extract solid samples, the sample must be free flowing when the solvent is added. Acidified anhydrous sodium sulfate should be added to clay type soils (normally 1:1), or any other solid that is not a free flowing sandy mixture, until a free flowing mixture is obtained.

7.2.1.3 Add 100 mL of methylene chloride/acetone (1:1 v/v) to the beaker. Perform ultrasonic extraction for 3 minutes, with output control knob set at 10 (full power) and with mode switch on Pulse (pulsing energy rather than continuous energy) and percent-duty cycle knob set at 50% (energy on 50% of time and off 50% of time). Allow the solids to settle. Transfer the organic layer into a 500-mL centrifuge bottle.

7.2.1.4 Ultrasonically extract the sample twice more using 100 mL of methylene chloride and the same ultrasonic conditions.

7.2.1.5 Combine the three organic extracts from the sample in the centrifuge bottle and centrifuge 10 minutes to settle the fine particles. Filter the combined extract through filter paper (Whatman #1, or equivalent) containing 7-10 g of acidified sodium sulfate into a 500-mL 24/40 Erlenmeyer flask. Add 10 g of acidified anhydrous sodium sulfate. Periodically, vigorously shake the extract and drying agent and allow the drying agent to remain in contact with the extract for a minimum of 2 hours. See NOTE in Sec. 7.3.6 that emphasizes the need for a dry extract prior to esterification.

7.2.1.6 Quantitatively transfer the contents of the flask to a 500-mL K-D flask with a 10-mL concentrator tube attached. Add boiling chips and attach the macro Snyder column. Evaporate the extract on the water bath to a volume of approximately 5 mL. Remove the flasks from the water bath and allow them to cool.

7.2.1.7 If hydrolysis or additional cleanup is not required and the sample is dry, proceed to Sec. 7.4.4. Otherwise, proceed to Sec. 7.2.3 for hydrolysis or Sec. 7.2.4 for cleanup.

7.2.2 Shaker extraction

7.2.2.1 Add 50 g (dry weight) of the well mixed, moist solid sample to a 500-mL wide-mouth Erlenmeyer flask. Adjust the pH to 2 with concentrated HCl and monitor the pH for 15 minutes with occasional stirring. If necessary, add additional HCl until the pH remains at 2. Spike the sample with surrogate(s) (Sec. 5.15).

7.2.2.2 Add 20 mL of acetone to the flask and mix the contents with the wrist shaker for 20 minutes. Add 80 mL diethyl ether to the same flask and shake again for 20 minutes. Decant the extract and measure the volume of solvent recovered.

7.2.2.3 Extract the sample twice more using 20 mL of acetone followed by 80 mL of diethyl ether. After addition of each solvent, the mixture should be shaken with the wrist shaker for 10 minutes and the acetone-ether extract decanted.

7.2.2.4 After the third extraction, the volume of extract recovered should be at least 75% of the volume of added solvent. If this is not the case, additional extractions may be necessary. Combine the extracts in a 2-L separatory funnel containing 250 mL of reagent water. If an emulsion forms, slowly add 5 g of acidified sodium sulfate (anhydrous) until the solvent-water mixture separates. A quantity of acidified sodium sulfate equal to the weight of the sample may be added, if necessary.

7.2.2.5 Check the pH of the extract. If it is not at or below pH 2, add more concentrated HCl until stabilized at the desired pH. Gently mix the contents of the separatory funnel for 1 minute and allow the layers to separate. Collect the aqueous phase in a clean beaker and the extract phase (top layer) in a 500-mL ground glass-

stoppered Erlenmeyer flask. Place the aqueous phase back into the separatory funnel and re-extract using 25 mL of diethyl ether. Allow the layers to separate and discard the aqueous layer. Combine the ether extracts in a 500-mL K-D flask.

7.2.2.6 If hydrolysis or additional cleanup is not required and the sample is dry, proceed to Sec. 7.4.4. Otherwise, proceed to Sec. 7.2.3 for hydrolysis or Sec. 7.2.4 for extract cleanup.

7.2.3 Hydrolysis of soil, sediment, or other solid sample extracts

Use this step only if herbicide esters in addition to herbicide acids are to be determined.

7.2.3.1 Add 5 mL of 37% aqueous potassium hydroxide and 30 mL of water to the extract. Add additional boiling chips to the K-D flask. Reflux the mixture on a water bath at 60 - 65°C until the hydrolysis step is completed (usually 1 - 2 hours). Remove the flasks from the water bath and cool to room temperature.

CAUTION: The presence of residual acetone will result in the formation of aldol condensation products which will cause GC interference.

7.2.3.2 Transfer the hydrolyzed aqueous solution to a 500-mL separatory funnel and extract the solution three times with 100-mL portions of methylene chloride. Discard the methylene chloride phase. At this point, the basic (aqueous) solution contains the herbicide salts.

7.2.3.3 Adjust the pH of the solution to <2 with cold (4°C) sulfuric acid (1:3) and extract once with 40 mL of diethyl ether and twice with 20-mL portions of ether. Combine the extracts and pour them through a pre-rinsed drying column containing 7 to 10 cm of acidified anhydrous sodium sulfate. Collect the dried extracts in a 500-mL Erlenmeyer flask (with a 24/40 joint) containing 10 g of acidified anhydrous sodium sulfate. Periodically, vigorously shake the extract and drying agent and allow the drying agent to remain in contact with the extract for a minimum of 2 hours. See NOTE in Sec. 7.3.6 that emphasizes the need for a dry extract prior to esterification. Quantitatively transfer the contents of the flask to a 500-mL Kuderna-Danish flask with a 10-mL concentrator tube attached when the extract is known to be dry.

7.2.3.4 Proceed to Sec. 7.4 for extract concentration. If additional cleanup is required, proceed to Sec. 7.2.4.

7.2.4 Cleanup of non-hydrolyzed herbicides

Use this step if additional cleanup of the non-hydrolyzed herbicides is required.

7.2.4.1 Partition the herbicides by extracting the methylene chloride from 7.2.1.7 (or diethyl ether from 7.2.3.4) three times with 15-mL portions of aqueous base prepared by carefully mixing 30 mL of reagent water into 15 mL of 37% aqueous potassium hydroxide. Discard the methylene chloride or ether phase. At this point the basic (aqueous) solution contains the herbicide salts.

7.2.4.2 Adjust the pH of the solution to <2 with cold (4°C) sulfuric acid (1:3) and extract once with 40 mL of diethyl ether and twice with 20-mL portions of ether. Combine the extracts and pour them through a pre-rinsed drying column containing 7-10 cm of

acidified anhydrous sodium sulfate. Collect the dried extracts in a 500-mL Erlenmeyer flask (with a 24/40 joint) containing 10 g of acidified anhydrous sodium sulfate. Periodically, vigorously shake the extract and drying agent and allow the drying agent to remain in contact with the extract for a minimum of 2 hours. See NOTE in Sec. 7.3.6 that emphasizes the need for a dry extract prior to esterification. Quantitatively transfer the contents of the flask to a 500-mL Kuderna-Danish flask with a 10-mL concentrator tube attached when the extract is known to be dry.

7.2.4.3 Proceed to Sec. 7.4 for extract concentration.

7.3 Preparation of aqueous samples

7.3.1 Using a graduated cylinder, transfer a 1-L sample aliquot to a 2-L separatory funnel. Spike the sample with surrogate compound(s) according to Sec. 5.15.

7.3.2 Add 250 g of NaCl to the sample, seal, and shake to dissolve the salt.

7.3.3 Use this step only if herbicide esters, in addition to herbicide acids, are to be determined

7.3.3.1 Add 17 mL of 6 N NaOH to the sample, seal, and shake. Check the pH of the sample with pH paper. If the sample does not have a pH greater than or equal to 12, adjust the pH by adding more 6 N NaOH. Let the sample sit at room temperature until the hydrolysis step is completed (usually 1 - 2 hours), shaking the separatory funnel and contents periodically.

7.3.3.2 Add 60 mL of methylene chloride to the sample bottle and rinse both the bottle and the graduated cylinder. Transfer the methylene chloride to the separatory funnel and extract the sample by vigorously shaking the funnel for 2 minutes, with periodic venting to release excess pressure. Allow the organic layer to separate from the water phase for a minimum of 10 minutes. If the emulsion interface between the layers is more than one-third the volume of the solvent layer, the analyst must employ mechanical techniques to complete the phase separation. The optimum technique depends upon the sample, but may include stirring, filtration through glass wool, centrifugation, or other physical methods. Discard the methylene chloride phase.

7.3.3.3 Add a second 60-mL volume of methylene chloride to the separatory funnel and repeat the extraction procedure a second time, discarding the methylene chloride layer. Perform a third extraction in the same manner.

7.3.4 Add 17 mL of cold (4°C) 12 N sulfuric acid to the sample (or hydrolyzed sample), seal, and shake to mix. Check the pH of the sample with pH paper. If the sample does not have a pH less than or equal to 2, adjust the pH by adding more acid.

7.3.5 Add 120 mL diethyl ether to the sample, seal, and extract the sample by vigorously shaking the funnel for 2 min with periodic venting to release excess pressure. Allow the organic layer to separate from the water phase for a minimum of 10 min. If the emulsion interface between layers is more than one third the volume of the solvent layer, the analyst must employ mechanical techniques to complete the phase separation. The optimum techniques to complete the phase separation depends upon the sample, but may include stirring, filtration through glass wool, centrifugation, or other physical methods. Remove the aqueous phase to a 2-L Erlenmeyer flask and collect the ether phase in a 500-mL Erlenmeyer

flask containing approximately 10 g of acidified anhydrous sodium sulfate. Periodically, vigorously shake the extract and drying agent.

7.3.6 Return the aqueous phase to the separatory funnel, add 60 mL of diethyl ether to the sample, and repeat the extraction procedure a second time, combining the extracts in the 500-mL Erlenmeyer flask. Perform a third extraction with 60 mL diethyl ether in the same manner. Allow the extract to remain in contact with the sodium sulfate for approximately 2 hours.

NOTE: The drying step is very critical to ensuring complete esterification. Any moisture remaining in the ether will result in low herbicide recoveries. The amount of sodium sulfate is adequate if some free flowing crystals are visible when swirling the flask. If all of the sodium sulfate solidifies in a cake, add a few additional grams of acidified sodium sulfate and again test by swirling. The 2 hour drying time is a minimum, however, the extracts may be held in contact with the sodium sulfate overnight.

7.3.7 Pour the dried extract through a funnel plugged with acid washed glass wool, and collect the extract in the K-D concentrator. Use a glass rod to crush any caked sodium sulfate during the transfer. Rinse the Erlenmeyer flask and funnel with 20 to 30 mL of diethyl ether to complete the quantitative transfer. Proceed to Sec. 7.4 for extract concentration.

7.4 Extract concentration

7.4.1 Add one or two clean boiling chips to the flask and attach a three-ball Snyder column. Prewet the Snyder column by adding about 1 mL of diethyl ether to the top of the column. Attach the solvent vapor recovery glassware (condenser and collection device) (Sec. 4.4.6) to the Snyder column of the K-D apparatus following manufacturer's instructions. Place the K-D apparatus on a hot water bath (15 - 20°C above the boiling point of the solvent) so that the concentrator tube is partially immersed in the hot water and the entire lower rounded surface of the flask is bathed with hot vapor. Adjust the vertical position of the apparatus and the water temperature, as required, to complete the concentration in 10 - 20 minutes. At the proper rate of distillation the balls of the column will actively chatter, but the chambers will not flood. When the apparent volume of liquid reaches 1 mL, remove the K-D apparatus from the water bath and allow it to drain and cool for at least 10 minutes.

7.4.2 Remove the Snyder column and rinse the flask and its lower joints into the concentrator tube with 1 - 2 mL of diethyl ether. The extract may be further concentrated by using either the micro Snyder column technique (Sec. 7.4.3) or nitrogen blowdown technique (Sec. 7.4.4).

7.4.3 Micro Snyder column technique

7.4.3.1 Add another one or two clean boiling chips to the concentrator tube and attach a two-ball micro Snyder column. Prewet the column by adding about 0.5 mL of diethyl ether to the top of the column. Place the K-D apparatus in a hot water bath so that the concentrator tube is partially immersed in the hot water. Adjust the vertical position of the apparatus and the water temperature, as required, to complete the concentration in 5-10 minutes. At the proper rate of distillation the balls of the column will actively chatter, but the chambers will not flood. When the apparent volume of liquid reaches 0.5 mL, remove the K-D apparatus from the water bath and allow it to drain and cool for at least 10 minutes. Remove the Snyder column, rinse the flask and its lower

joints with about 0.2 mL of diethyl ether and add to the concentrator tube. Proceed to Sec. 7.4.5.

7.4.4 Nitrogen blowdown

7.4.4.1 Place the concentrator tube in a warm water bath (approximately 35°C) and evaporate the solvent volume to the required level using a gentle stream of clean, dry nitrogen (filtered through a column of activated carbon).

CAUTION: Do not use plasticized tubing between the carbon trap and the sample.

7.4.4.2 The internal wall of the tube must be rinsed down several times with diethyl ether during the operation. During evaporation, the solvent level in the tube must be positioned to prevent water from condensing into the sample (i.e., the solvent level should be below the level of the water bath). Under normal operating conditions, the extract should not be allowed to become dry. Proceed to Sec. 7.4.5.

7.4.5 Dilute the extract with 1 mL of isooctane and 0.5 mL of methanol. Dilute to a final volume of 4 mL with diethyl ether. The sample is now ready for methylation with diazomethane. If PFB derivation is being performed, dilute to 4 mL with acetone.

7.5 Esterification - For diazomethane derivatization proceed with Sec. 7.5.1. For PFB derivatization proceed with Sec. 7.5.2.

7.5.1 Diazomethane derivatization - Two methods may be used for the generation of diazomethane: the bubbler method (see Figure 1), Sec. 7.5.1.1, and the Diazald kit method, Sec. 7.5.1.2.

CAUTION: Diazomethane is a carcinogen and can explode under certain conditions.

The bubbler method is suggested when small batches of samples (10 - 15) require esterification. The bubbler method works well with samples that have low concentrations of herbicides (e.g., aqueous samples) and is safer to use than the Diazald kit procedure. The Diazald kit method is good for large quantities of samples needing esterification. The Diazald kit method is more effective than the bubbler method for soils or samples that may contain high concentrations of herbicides (e.g., samples such as soils that may result in yellow extracts following hydrolysis may be difficult to handle by the bubbler method).

The diazomethane derivatization procedures described below will react efficiently with all of the chlorinated herbicides described in this method and should be used only by experienced analysts, due to the potential hazards associated with its use.

The following precautions should be taken:

- Use a safety screen.
- Use mechanical pipetting aides.
- Do not heat above 90°C - EXPLOSION may result.
- Avoid grinding surfaces, ground-glass joints, sleeve bearings, and glass stirrers - EXPLOSION may result.

Store away from alkali metals - EXPLOSION may result.
Solutions of diazomethane decompose rapidly in the presence of solid materials such as copper powder, calcium chloride, and boiling chips.

7.5.1.1 Bubbler method - Assemble the diazomethane bubbler (see Figure 1).

7.5.1.1.1 Add 5 mL of diethyl ether to the first test tube. Add 1 mL of diethyl ether, 1 mL of carbitol, 1.5 mL of 37% KOH, and 0.1 - 0.2 g of Diazald to the second test tube. Immediately place the exit tube into the concentrator tube containing the sample extract. Apply nitrogen flow (10 mL/min) to bubble diazomethane through the extract for 10 minutes or until the yellow color of diazomethane persists. The amount of Diazald used is sufficient for esterification of approximately three sample extracts. An additional 0.1 - 0.2 g of Diazald may be added (after the initial Diazald is consumed) to extend the generation of the diazomethane. There is sufficient KOH present in the original solution to perform a maximum of approximately 20 minutes of total esterification.

7.5.1.1.2 Remove the concentrator tube and seal it with a Neoprene or PTFE stopper. Store at room temperature in a hood for 20 minutes.

7.5.1.1.3 Destroy any unreacted diazomethane by adding 0.1 - 0.2 g of silicic acid to the concentrator tube. Allow to stand until the evolution of nitrogen gas has stopped. Adjust the sample volume to 10.0 mL with hexane. Stopper the concentrator tube or transfer 1 mL of sample to a GC vial, and store refrigerated if further processing will not be performed immediately. Analyze by gas chromatography.

7.5.1.1.4 Extracts should be stored at 4°C away from light. Preservation study results indicate that most analytes are stable for 28 days; however, it is recommended that the methylated extracts be analyzed immediately to minimize the trans-esterification and other potential reactions that may occur.

7.5.1.2 Diazald kit method - Instructions for preparing diazomethane are provided with the generator kit.

7.5.1.2.1 Add 2 mL of diazomethane solution and let the sample stand for 10 minutes with occasional swirling. The yellow color of diazomethane should be evident and should persist for this period.

7.5.1.2.2 Rinse the inside wall of the ampule with 700 µL of diethyl ether. Reduce the sample volume to approximately 2 mL to remove excess diazomethane by allowing the solvent to evaporate spontaneously at room temperature. Alternatively, 10 mg of silicic acid can be added to destroy the excess diazomethane.

7.5.1.2.3 Dilute the sample to 10.0 mL with hexane. Analyze by gas chromatography. It is recommended that the methylated extracts be analyzed immediately to minimize the trans-esterification and other potential reactions that may occur.

7.5.2 PFB derivatization

7.5.2.1 Add 30 μL of 10% K_2CO_3 and 200 μL of 3% PFBBr in acetone. Close the tube with a glass stopper and mix on a vortex mixer. Heat the tube at 60°C for 3 hours.

7.5.2.2 Evaporate the solution to 0.5 mL with a gentle stream of nitrogen. Add 2 mL of hexane and repeat evaporation just to dryness at ambient temperature.

7.5.2.3 Redissolve the residue in 2 mL of toluene:hexane (1:6) for column cleanup.

7.5.2.4 Top a silica column (Bond Elut™ or equivalent) with 0.5 cm of anhydrous sodium sulfate. Prewet the column with 5 mL hexane and let the solvent drain to the top of the adsorbent. Quantitatively transfer the reaction residue to the column with several rinsings of the toluene:hexane solution (total 2 - 3 mL).

7.5.2.5 Elute the column with sufficient toluene:hexane to collect 8 mL of eluent. Discard this fraction, which contains excess reagent.

7.5.2.6 Elute the column with toluene:hexane (9:1) to collect 8 mL of eluent containing PFB derivatives in a 10-mL volumetric flask. Dilute to 10 mL with hexane. Analyze by GC/ECD.

7.6 Gas chromatographic conditions (recommended)

7.6.1 Narrow-bore columns

Temperature program:	60°C to 300°C, at 4°C/min
Helium carrier flow:	30 cm/sec
Injection volume:	2 μL , splitless, 45 sec delay
Injector temperature:	250°C
Detector temperature:	320°C

7.6.2 Wide-bore columns

Temperature program:	0.5 minute at 150°C, 150°C to 270°C, at 5°C/min
Helium carrier flow:	7 mL/min
Injection volume:	1 μL
Injector temperature:	250°C
Detector temperature:	320°C

7.7 Calibration

The procedure for internal or external calibration may be used. Refer to Method 8000 for a description of each of these procedures. Use Table 1 for guidance on selecting the lowest point on the calibration curve.

7.8 Gas chromatographic analysis of samples

7.8.1 Refer to Method 8000. If the internal standard calibration technique is used, add 10 μL of internal standard to the sample prior to injection.

7.8.2 Follow Method 8000 for instructions on the analysis sequence, appropriate dilutions, establishing daily retention time windows, and identification criteria. Include a mid-concentration standard after each group of 10 samples in the analysis sequence.

7.8.3 An example of a chromatogram for a methylated chlorophenoxy herbicide is shown in Figure 2. Tables 2 and 3 present retention times for the target analytes after esterification, using the diazomethane derivatization procedure and the PFBBr derivatization procedure, respectively.

7.8.4 Record the sample volume injected and the resulting peak sizes (in area units or peak heights).

7.8.5 Using either the internal or external calibration procedure (Method 8000), determine the identity and quantity of each component peak in the sample chromatogram which corresponds to the compounds used for calibration purposes.

7.8.6 If calibration standards have been analyzed in the same manner as the samples (e.g., have undergone hydrolysis and esterification), then the calculation of concentration given in Method 8000 should be used. However, if calibration is performed using standards made from methyl ester compounds (compounds not esterified by application of this method), then the calculation of concentration must include a correction for the molecular weight of the methyl ester versus the acid herbicide.

7.8.7 If peak detection and identification are prevented due to interferences, further cleanup is required. Before using any cleanup procedure, the analyst must process a series of standards through the procedure to validate elution patterns and the absence of interferences from reagents.

7.9 GC/MS confirmation

7.9.1 GC/MS techniques should be judiciously employed to support qualitative identifications made with this method. Refer to Method 8270 for the appropriate GC/MS operating conditions and analysis procedures.

7.9.2 When available, chemical ionization mass spectra may be employed to aid the qualitative identification process.

7.9.3 Should these MS procedures fail to provide satisfactory results, additional steps may be taken before reanalysis. These steps may include the use of alternate GC columns or additional cleanup.

8.0 QUALITY CONTROL

8.1 Refer to Chapter One and Method 8000 for specific quality control (QC) procedures. Quality control procedures to ensure the proper operation of the various sample preparation and/or sample introduction techniques can be found in Method 3500. Each laboratory should maintain a

formal quality assurance program. The laboratory should also maintain records to document the quality of the data generated.

8.2 Quality control procedures necessary to evaluate the GC system operation are found in Method 8000, Sec. 7.0 and include evaluation of retention time windows, calibration verification and chromatographic analysis of samples.

8.3 Initial Demonstration of Proficiency - Each laboratory must demonstrate initial proficiency with each sample preparation and determinative method combination it utilizes, by generating data of acceptable accuracy and precision for target analytes in a clean matrix. The laboratory must also repeat the following operations whenever new staff are trained or significant changes in instrumentation are made. See Method 8000, Sec. 8.0 for information on how to accomplish this demonstration.

8.4 Sample Quality Control for Preparation and Analysis - The laboratory must also have procedures for documenting the effect of the matrix on method performance (precision, accuracy, and detection limit). At a minimum, this includes the analysis of QC samples including a method blank, matrix spike, a duplicate, and a laboratory control sample (LCS) in each analytical batch and the addition of surrogates to each field sample and QC sample.

8.4.1 Before processing any samples, the analyst should demonstrate, through the analysis of a method blank, that interferences from the analytical system, glassware, and reagents are under control. Each time a set of samples is analyzed or there is a change in reagents, a method blank should be analyzed as a safeguard against chronic laboratory contamination. The blanks should be carried through all stages of sample preparation and measurement.

8.4.2 Documenting the effect of the matrix should include the analysis of at least one matrix spike and one duplicate unspiked sample or one matrix spike/matrix spike duplicate pair. The decision on whether to prepare and analyze duplicate samples or a matrix spike/matrix spike duplicate must be based on a knowledge of the samples in the sample batch. If samples are expected to contain target analytes, then laboratories may use one matrix spike and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes, laboratories should use a matrix spike and matrix spike duplicate pair.

8.4.3 A Laboratory Control Sample (LCS) should be included with each analytical batch. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS is spiked with the same analytes at the same concentrations as the matrix spike. When the results of the matrix spike analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix.

8.4.4 See Method 8000, Sec. 8.0 for the details on carrying out sample quality control procedures for preparation and analysis.

8.5 Surrogate recoveries - The laboratory must evaluate surrogate recovery data from individual samples versus the surrogate control limits developed by the laboratory. See Method 8000, Sec. 8.0 for information on evaluating surrogate data and developing and updating surrogate limits.

8.6 It is recommended that the laboratory adopt additional quality assurance practices for use with this method. The specific practices that are most productive depend upon the needs of the

laboratory and the nature of the samples. Whenever possible, the laboratory should analyze standard reference materials and participate in relevant performance evaluation studies.

9.0 METHOD PERFORMANCE

9.1 In single laboratory studies using organic-free reagent water and clay/still bottom samples, the mean recoveries presented in Tables 4 and 5 were obtained for diazomethane derivatization. The standard deviations of the percent recoveries of these measurements are also in Tables 4 and 5.

9.2 Table 6 presents relative recoveries of the target analytes obtained using the PFBBr derivatization procedure with spiked water samples.

^a EDL = estimated detection limit; defined as either the MDL, or a concentration of analyte in a sample yielding a peak in the final extract with signal-to-noise ratio of approximately 5, whichever value is higher.

^b Detection limits determined from standard solutions corrected back to 50-g samples, extracted and concentrated to 10 mL, with 5 µL injected. Chromatography using narrow-bore capillary column, 0.25 µm film, 5% phenyl/95% methyl silicone.

^c The minimum amount of analyte to give a Finnigan INCOS FIT value of 800 as the methyl derivative vs. the spectrum obtained from 50 ng of the respective free acid herbicide.

^d From Method 1658, "The Determination of Phenoxy-Acid Herbicides in Municipal and Industrial Wastewater", Methods for the Determination of Nonconventional Pesticides in Municipal and Industrial Wastewater, EPA-821-R-93-010-A, the USEPA Office of Water, Engineering and Analysis Division. MDLs were obtained with an electrolytic conductivity detector.

^e DCPA monoacid and diacid metabolites included in method scope; DCPA diacid metabolite used for validation studies. DCPA is a dimethyl ester.

Semivolatile Organics

SW-846 Method 8270D

METHOD 8270D

SEMIVOLATILE ORGANIC COMPOUNDS
BY GAS CHROMATOGRAPHY/MASS SPECTROMETRY (GC/MS)

SW-846 is not intended to be an analytical training manual. Therefore, method procedures are written based on the assumption that they will be performed by analysts who are formally trained in at least the basic principles of chemical analysis and in the use of the subject technology.

In addition, SW-846 methods, with the exception of required method use for the analysis of method-defined parameters, are intended to be guidance methods which contain general information on how to perform an analytical procedure or technique which a laboratory can use as a basic starting point for generating its own detailed Standard Operating Procedure (SOP), either for its own general use or for a specific project application. The performance data included in this method are for guidance purposes only, and are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

1.0 SCOPE AND APPLICATION

1.1 This method is used to determine the concentration of semivolatile organic compounds in extracts prepared from many types of solid waste matrices, soils, air sampling media and water samples. Direct injection of a sample may be used in limited applications. The following RCRA analytes have been determined by this method:

Compounds	CAS No ^a	Appropriate Preparation Techniques ^b

KEY TO ANALYTE LIST

AW = Adsorption to walls of glassware during extraction and storage.

CP = Nonreproducible chromatographic performance.

DC = Unfavorable distribution coefficient.

HE = Hydrolysis during extraction accelerated by acidic or basic conditions.

HS = Hydrolysis during storage potential.

LR = Low response.

ND = Not determined.

OE = Oxidation during extraction accelerated by basic conditions.

OS = Oxidation during storage potential.

X = Historically, adequate recovery can be obtained by this technique. However, actual recoveries may vary depending on the extraction efficiency, the number of constituents being analyzed concurrently, and the analytical instrumentation.

1.2 In addition to the sample preparation methods listed in the above analyte list, Method 3535 describes a solid-phase extraction procedure that may be applied to the extraction of semivolatiles from TCLP leachates (see Tables 16 and 17 of this method for performance data). Method 3542 describes sample preparation for semivolatile organic compounds in air sampled by Method 0010 (see Table 11 of this method for surrogate performance data), Method 3545 describes an automated solvent extraction device for semivolatiles in solids (see Table 12 of this method for performance data), Method 3561 describes a supercritical fluid device for the extraction of PAHs from solids (see Tables 13, 14, and 15 of this method for performance data), and Method 3546 provides an extraction procedure employing commercially available microwave equipment to extract semivolatiles while using less solvent and taking less time than procedures such as a Soxhlet extraction (see Tables 19 through 23 of this method for the applicable performance data). (The tabulated data are provided for guidance purposes only.)

1.3 This method can be used to quantitate most neutral, acidic, and basic organic compounds that are soluble in methylene chloride (or other suitable solvents provided that the desired performance data can be generated) and are capable of being eluted, without derivatization, as sharp peaks from a gas chromatographic fused-silica capillary column coated with a slightly polar silicone. Such compounds include polynuclear aromatic hydrocarbons, chlorinated hydrocarbons and pesticides, phthalate esters, organophosphate esters, nitrosamines, haloethers, aldehydes, ethers, ketones, anilines, pyridines, quinolines, aromatic

nitro compounds, and phenols, including nitrophenols. See Table 1 for a list of compounds and their characteristic ions that have been evaluated.

In most cases, this method is not appropriate for the quantitation of multicomponent analytes, e.g., Aroclors, Toxaphene, Chlordane, etc., because of limited sensitivity for those analytes. When these analytes have been identified by another technique, Method 8270 may be appropriate for confirmation of the identification of these analytes when concentration in the extract permits. Refer to Methods 8081 and 8082 for guidance on calibration and quantitation of multicomponent analytes such as the Aroclors, Toxaphene, and Chlordane.

1.4 The following compounds may require special treatment when being determined by this method:

1.4.1 Benzidine may be subject to oxidative losses during solvent concentration and its chromatographic behavior is poor.

1.4.2 Under the alkaline conditions of the extraction step from aqueous matrices, α -BHC, γ -BHC, Endosulfan I and II, and Endrin are subject to decomposition. Neutral extraction should be performed if these compounds are expected to be present.

1.4.3 Hexachlorocyclopentadiene is subject to thermal decomposition in the inlet of the gas chromatograph, chemical reaction in acetone solution, and photochemical decomposition.

1.4.4 N-nitrosodimethylamine is difficult to separate from the solvent under the chromatographic conditions described.

1.4.5 N-nitrosodiphenylamine decomposes in the gas chromatographic inlet and cannot be separated from diphenylamine. For this reason, it is acceptable to report the combined result for n-nitrosodiphenylamine and diphenylamine for either of these compounds as a combined concentration.

1.4.6 1,2-Diphenylhydrazine is unstable even at room temperature and readily converts to azobenzene. Given the stability problems, it would be acceptable to calibrate for 1,2-diphenylhydrazine using azobenzene. Under these poor compound separation circumstances the results for either of these compounds should be reported as a combined concentration.

1.4.7 Pentachlorophenol, 2,4-dinitrophenol, 4-nitrophenol, benzoic acid, 4,6-dinitro-2-methylphenol, 4-chloro-3-methylphenol, 2-nitroaniline, 3-nitroaniline, 4-nitroaniline, and benzyl alcohol are subject to erratic chromatographic behavior, especially if the GC system is contaminated with high boiling material.

1.4.8 Pyridine may perform poorly at the GC injection port temperatures listed in this method. Lowering the injection port temperature may reduce the amount of degradation. However, the analyst must use caution in modifying the injection port temperature, as the performance of other analytes may be adversely affected. Therefore, if pyridine is to be determined in addition to other target analytes, it may be necessary to perform separate analyses. In addition, pyridine may be lost during the evaporative concentration of the sample extract. As a result, many of the extraction methods listed above may yield low recoveries unless great care is exercised during the concentration steps. For this reason, analysts may wish to consider the use of extraction techniques such as pressurized fluid extraction (Method 3545), microwave extraction (Method 3546),

or supercritical fluid extraction, which involve smaller extract volumes, thereby reducing or eliminating the need for evaporative concentration techniques for many applications.

1.4.9 Toluene diisocyanate rapidly hydrolyzes in water (half-life of less than 30 min). Therefore, recoveries of this compound from aqueous matrices should not be expected. In addition, in solid matrices, toluene diisocyanate often reacts with alcohols and amines to produce urethane and ureas and consequently cannot usually coexist in a solution containing these materials.

1.4.10 In addition, analytes in the list provided above are flagged when there are limitations caused by sample preparation and/or chromatographic problems.

1.5 The lower limits of quantitation for this method when determining an individual compound are approximately 660 µg/kg (wet weight) for soil/sediment samples, 1-200 mg/kg for wastes (dependent on matrix and method of preparation), and 10 µg/L for ground water samples (see Table 2). Lower limits of quantitation will be proportionately higher for sample extracts that require dilution to avoid saturation of the detector. The lower limits of quantitation listed in Table 2 are provided for guidance and may not always be achievable.

1.6 Prior to employing this method, analysts are advised to consult the base method for each type of procedure that may be employed in the overall analysis (e.g., Methods 3500, 3600, 5000, and 8000) for additional information on quality control procedures, development of QC acceptance criteria, calculations, and general guidance. Analysts also should consult the disclaimer statement at the front of the manual and the information in Chapter Two for guidance on the intended flexibility in the choice of methods, apparatus, materials, reagents, and supplies, and on the responsibilities of the analyst for demonstrating that the techniques employed are appropriate for the analytes of interest, in the matrix of interest, and at the levels of concern.

In addition, analysts and data users are advised that, except where explicitly specified in a regulation, the use of SW-846 methods is *not* mandatory in response to Federal testing requirements. The information contained in this method is provided by EPA as guidance to be used by the analyst and the regulated community in making judgments necessary to generate results that meet the data quality objectives for the intended application.

1.7 Use of this method is restricted to use by, or under supervision of, personnel appropriately experienced and trained in the use of gas chromatograph/mass spectrometers and skilled in the interpretation of mass spectra. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 The samples are prepared for analysis by gas chromatography/mass spectrometry (GC/MS) using the appropriate sample preparation (refer to Method 3500) and, if necessary, sample cleanup procedures (refer to Method 3600).

2.2 The semivolatile compounds are introduced into the GC/MS by injecting the sample extract into a gas chromatograph (GC) equipped with a narrow-bore fused-silica capillary column. The GC column is temperature-programmed to separate the analytes, which are then detected with a mass spectrometer (MS) connected to the gas chromatograph.

2.3 Analytes eluted from the capillary column are introduced into the mass spectrometer via a jet separator or a direct connection. Identification of target analytes is

accomplished by comparing their mass spectra with the electron impact (or electron impact-like) spectra of authentic standards. Quantitation is accomplished by comparing the response of a major (quantitation) ion relative to an internal standard using an appropriate calibration curve for the intended application.

2.4 This method includes specific calibration and quality control steps that supersede the general recommendations provided in Method 8000.

3.0 DEFINITIONS

Refer to Chapter One and the manufacturer's instructions for definitions that may be relevant to this procedure.

4.0 INTERFERENCES

4.1 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All of these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks. Specific selection of reagents and purification of solvents by distillation in all-glass systems may be necessary. Refer to each method to be used for specific guidance on quality control procedures and to Chapter Four for general guidance on the cleaning of glassware. Also refer to Method 8000 for a discussion of interferences.

4.2 Raw GC/MS data from all blanks, samples, and spikes must be evaluated for interferences. Determine if the source of interference is in the preparation and/or cleanup of the samples and take corrective action to eliminate the problem.

4.3 Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed. To reduce carryover, the sample syringe must be rinsed with solvent between sample injections. Whenever an unusually concentrated sample is encountered, it should be followed by the analysis of solvent to check for cross-contamination.

5.0 SAFETY

This method does not address all safety issues associated with its use. The laboratory is responsible for maintaining a safe work environment and a current awareness file of OSHA regulations regarding the safe handling of the chemicals listed in this method. A reference file of material safety data sheets (MSDSs) should be available to all personnel involved in these analyses.

6.0 EQUIPMENT AND SUPPLIES

The mention of trade names or commercial products in this manual is for illustrative purposes only, and does not constitute an EPA endorsement or exclusive recommendation for use. The products and instrument settings cited in SW-846 methods represent those products and settings used during method development or subsequently evaluated by the Agency. Glassware, reagents, supplies, equipment, and settings other than those listed in this manual may be employed provided that method performance appropriate for the intended application has been demonstrated and documented.

This section does not list common laboratory glassware (e.g., beakers and flasks).

6.1 Gas chromatograph/mass spectrometer system

6.1.1 Gas chromatograph -- An analytical system equipped with a temperature-programmable gas chromatograph suitable for splitless injection and all required accessories, including syringes, analytical columns, and gases. The capillary column should be directly coupled to the source.

6.1.2 Column -- 30-m x 0.25-mm ID (or 0.32-mm ID) 0.25, 0.5, or 1- μ m film thickness silicone-coated fused-silica capillary column (J&W Scientific DB-5 or equivalent). The columns listed in this section were the columns used in developing the method. The listing of these columns in this method is not intended to exclude the use of other columns that may be developed. Laboratories may use these columns or other capillary columns provided that the laboratories document method performance data (e.g., chromatographic resolution, analyte breakdown, and sensitivity) that are appropriate for the intended application.

6.1.3 Mass spectrometer

6.1.3.1 Capable of scanning from 35 to 500 amu every 1 sec or less, using 70 volts (nominal) electron energy in the electron impact ionization mode. The mass spectrometer must be capable of producing a mass spectrum for decafluorotriphenylphosphine (DFTPP) which meets the criteria as outlined in Sec. 11.3.1.

6.1.3.2 An ion trap mass spectrometer may be used if it is capable of axial modulation to reduce ion-molecule reactions and can produce electron impact-like spectra that match those in the EPA/NIST Library. The mass spectrometer must be capable of producing a mass spectrum for DFTPP which meets the criteria as outlined in Sec. 11.3.1

6.1.4 GC/MS interface -- Any GC-to-MS interface may be used that gives acceptable calibration points for each compound of interest and achieves acceptable tuning performance criteria. For a narrow-bore capillary column, the interface is usually capillary-direct into the mass spectrometer source.

6.1.5 Data system -- A computer system should be interfaced to the mass spectrometer. The system must allow the continuous acquisition and storage on machine-readable media of all mass spectra obtained throughout the duration of the chromatographic program. The computer should have software that can search any GC/MS data file for ions of a specific mass and that can plot such ion abundances versus time or scan number. This type of plot is defined as an Extracted Ion Current Profile (EICP). Software should also be available that allows integrating the abundances in any EICP between specified time or scan-number limits. The most recent version of the EPA/NIST Mass Spectral Library should also be available.

6.1.6 Guard column (optional) -- (J&W deactivated fused-silica, 0.25-mm ID x 6-m, or equivalent) between the injection port and the analytical column joined with column connectors (Agilent Catalog No. 5062-3556, or equivalent).

6.2 Syringe -- 10- μ L.

- 6.3 Volumetric flasks, Class A -- Appropriate sizes equipped with ground-glass stoppers.
- 6.4 Balance -- Analytical, capable of weighing 0.0001 g.
- 6.5 Bottles -- Glass equipped with polytetrafluoroethylene (PTFE)-lined screw caps or crimp tops.

7.0 REAGENTS AND STANDARDS

7.1 Reagent-grade chemicals must be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. Reagents should be stored in glass to prevent the leaching of contaminants from plastic containers.

7.2 Organic-free reagent water -- All references to water in this method refer to organic-free reagent water.

7.3 Standard solutions

The following sections describe the preparation of stock, intermediate, and working standards for the compounds of interest. This discussion is provided as an example, and other approaches and concentrations of the target compounds may be used, as appropriate for the intended application. See Method 8000 for additional information on the preparation of calibration standards.

7.4 Stock standard solutions (1000 mg/L) -- Standard solutions can be prepared from pure standard materials or purchased as certified solutions.

7.4.1 Prepare stock standard solutions by accurately weighing about 0.0100 g of pure material. Dissolve the material in pesticide quality acetone or other suitable solvent and dilute to volume in a 10-mL volumetric flask. Larger volumes can be used at the convenience of the analyst. When compound purity is assayed to be 96% or greater, the weight may be used without correction to calculate the concentration of the stock standard. Commercially-prepared stock standards may be used at any concentration if they are certified by the manufacturer or by an independent source.

7.4.2 Transfer the stock standard solutions into bottles equipped with PTFE-lined screw-caps. Store, protected from light, at #6 EC or as recommended by the standard manufacturer. Stock standard solutions should be checked frequently for signs of degradation or evaporation, especially just prior to preparing calibration standards from them.

7.4.3 Stock standard solutions must be replaced after 1 year or sooner if comparison with quality control check samples indicates a problem.

7.4.4 It is recommended that nitrosamine compounds be placed together in a separate calibration mix and not combined with other calibration mixes. When using a premixed certified standard, consult the manufacturer's instructions for additional guidance.

7.4.5 Mixes with hydrochloride salts may contain hydrochloric acid, which can cause analytical difficulties. When using a premixed certified standard, consult the manufacturer's instructions for additional guidance.

7.5 Internal standard solutions -- The internal standards recommended are 1,4-dichlorobenzene- d_4 , naphthalene- d_8 , acenaphthene- d_{10} , phenanthrene- d_{10} , chrysene- d_{12} , and perylene- d_{12} (see Table 5). Other compounds may be used as internal standards as long as the criteria in Sec. 11.3.2 are met.

7.5.1 Dissolve 0.200 g of each compound with a small volume of carbon disulfide. Transfer to a 50-mL volumetric flask and dilute to volume with methylene chloride so that the final solvent is approximately 20% carbon disulfide. Most of the compounds are also soluble in small volumes of methanol, acetone, or toluene, except for perylene- d_{12} . The resulting solution will contain each standard at a concentration of 4,000 ng/ μ L. Each 1-mL sample extract undergoing analysis should be spiked with 10 μ L of the internal standard solution, resulting in a concentration of 40 ng/ μ L of each internal standard. Store away from any light source at #6 EC when not in use (-10 EC is recommended). When using premixed certified solutions, store according to the manufacturer's documented holding time and storage temperature recommendations.

7.5.2 If a more sensitive mass spectrometer is employed to achieve lower quantitation levels, a more dilute internal standard solution may be required. Area counts of the internal standard peaks should be between 50-200% of the area of the target analytes in the mid-point calibration analysis.

7.6 GC/MS tuning standard -- A methylene chloride solution containing 50 ng/ μ L of decafluorotriphenylphosphine (DFTPP) should be prepared. The standard should also contain 50 ng/ μ L each of 4,4'-DDT, pentachlorophenol, and benzidine to verify injection port inertness and GC column performance. Alternate concentrations may be used to compensate for different injection volumes if the total amount injected is 50 ng or less. Store away from any light source at #6 EC when not in use (-10 EC is recommended). If a more sensitive mass spectrometer is employed to achieve lower quantitation levels, a more dilute tuning solution may be necessary. When using premixed certified solutions, store according to the manufacturer's documented holding time and storage temperature recommendations.

7.7 Calibration standards -- A minimum of five calibration standards should be prepared at different concentrations. At least one of the calibration standards should correspond to a sample concentration at or below that necessary to meet the data quality objectives of the project. The remaining standards should correspond to the range of concentrations found in actual samples but should not exceed the working range of the GC/MS system. Each standard and/or series of calibration standards prepared at a given concentration should contain all the desired project-specific target analytes for which quantitation and quantitative results are to be reported by this method.

7.7.1 It is the intent of EPA that all target analytes for a particular analysis be included in the calibration standard(s). These target analytes may not include the entire list of analytes (Sec. 1.1) for which the method has been demonstrated. However, the laboratory shall not report a quantitative result for a target analyte that was not included in the calibration standard(s).

7.7.2 Each 1-mL aliquot of calibration standard should be spiked with 10 μ L of the internal standard solution prior to analysis. All standards should be stored away from any light source at #6 EC when not in use (-10 EC is recommended), and should be freshly prepared once a year, or sooner if check standards indicate a problem. The calibration

verification standard should be prepared, as necessary, and stored at #6 EC. When using premixed certified solutions, store according to the manufacturer's documented holding time and storage temperature recommendations.

7.8 Surrogate standards -- The recommended surrogates are phenol- d_6 , 2-fluorophenol, 2,4,6-tribromophenol, nitrobenzene- d_5 , 2-fluorobiphenyl, and p-terphenyl- d_{14} . See Method 3500 for instructions on preparing the surrogate solutions.

NOTE: In the presence of samples containing residual chlorine, phenol- d_6 has been known to react to form chlorinated phenolic compounds that are not detected as the original spiked surrogate. Sample preservation precautions outlined in Chapter Four should be used when residual chlorine is known to be present in order to minimize degradation of deuterated phenols or any other susceptible target analyte.

7.8.1 Surrogate standard check -- Determine what the appropriate concentration should be for the blank extracts after all extraction, cleanup, and concentration steps. Inject this concentration into the GC/MS to determine recovery of surrogate standards. It is recommended that this check be done whenever a new surrogate spiking solution is prepared.

NOTE: Method 3561 (SFE Extraction of PAHs) recommends the use of bromobenzene and p-quaterphenyl to better cover the range of PAHs listed in the method.

7.8.2 If a more sensitive mass spectrometer is employed to achieve lower quantitation levels, a more dilute surrogate solution may be necessary.

7.9 Matrix spike and laboratory control standards -- See Method 3500 for instructions on preparing the matrix spike standard. The same standard may be used as the laboratory control standard (LCS) and the spiking solution should be the same source as used for the initial calibration standards to restrict the influence of standard accuracy on the determination of recovery through preparation and analysis.

7.9.1 Matrix spike check -- Determine what concentration should be in the blank extracts after all extraction, cleanup, and concentration steps. Inject this concentration into the GC/MS to determine recovery. It is recommended that this check be done whenever a new matrix spiking solution is prepared.

7.9.2 If a more sensitive mass spectrometer is employed to achieve lower quantitation levels, a more dilute matrix and LCS spiking solution may be necessary.

7.9.3 Some projects may require the spiking of the specific compounds of interest, since the spiking compounds listed in Method 3500 would not be representative of the compounds of interest required for the project. When this occurs, the matrix and LCS spiking standards should be prepared in methanol, with each compound present at a concentration appropriate for the project.

7.10 Solvents -- Acetone, hexane, methylene chloride, isooctane, carbon disulfide, toluene, and other appropriate solvents. All solvents should be pesticide quality or equivalent. Solvents may be degassed prior to use.

8.0 SAMPLE COLLECTION, PRESERVATION, AND STORAGE

8.1 See the introductory material to Chapter Four, "Organic Analytes."

8.2 Store the sample extracts at #6 EC, protected from light, in sealed vials (e.g., screw-cap vials or crimp-capped vials) equipped with unpierced PTFE-lined septa.

9.0 QUALITY CONTROL

9.1 Refer to Chapter One for guidance on quality assurance (QA) and quality control (QC) protocols. When inconsistencies exist between QC guidelines, method-specific QC criteria take precedence over both technique-specific criteria and those criteria given in Chapter One, and technique-specific QC criteria take precedence over the criteria in Chapter One. Any effort involving the collection of analytical data should include development of a structured and systematic planning document, such as a Quality Assurance Project Plan (QAPP) or a Sampling and Analysis Plan (SAP), which translates project objectives and specifications into directions for those that will implement the project and assess the results. Each laboratory should maintain a formal quality assurance program. The laboratory should also maintain records to document the quality of the data generated. All data sheets and quality control data should be maintained for reference or inspection.

9.2 Refer to Method 8000 for specific determinative method QC procedures. Refer to Method 3500 or 5000 for QC procedures to ensure the proper operation of the various sample preparation techniques. If an extract cleanup procedure is performed, refer to Method 3600 for the appropriate QC procedures. Any more specific QC procedures provided in this method will supersede those noted in Methods 8000, 5000, 3500, or 3600.

9.3 Quality control procedures necessary to evaluate the GC system operation are found in Method 8000 and include evaluation of retention time windows, calibration verification and chromatographic analysis of samples. In addition, discussions regarding the instrument QC requirements listed below can be found in the referenced sections of this method:

- The GC/MS must be tuned to meet the recommended DFTPP criteria prior to the initial calibration and for each 12-hr period during which analyses are performed. See Secs. 11.3.1 and 11.4.1 for further details.
- There must be an initial calibration of the GC/MS system as described in Sec. 11.3. In addition, the initial calibration curve should be verified immediately after performing the standard analyses using a second source standard (prepared using standards different from the calibration standards). The suggested acceptance limits for this initial calibration verification analysis are 70 - 130%. Alternative acceptance limits may be appropriate based on the desired project-specific data quality objectives. Quantitative sample analyses should not proceed for those analytes that fail the second source standard initial calibration verification. However, analyses may continue for those analytes that fail the criteria with an understanding these results could be used for screening purposes and would be considered estimated values.
- The GC/MS system must meet the calibration verification acceptance criteria in Sec. 11.4, each 12 hrs.
- The RRT of the sample component must fall within the RRT window of the standard component provided in Sec. 11.6.1.

9.4 Initial demonstration of proficiency

Each laboratory must demonstrate initial proficiency with each sample preparation and determinative method combination it utilizes by generating data of acceptable accuracy and precision for target analytes in a clean matrix. The laboratory must also repeat the following operations whenever new staff members are trained or significant changes in instrumentation are made. See Method 8000 for information on how to accomplish a demonstration of proficiency.

9.5 Initially, before processing any samples, the analyst should demonstrate that all parts of the equipment in contact with the sample and reagents are interference-free. This is accomplished through the analysis of a method blank. As a continuing check, each time samples are extracted, cleaned up, and analyzed, a method blank must be prepared and analyzed for the compounds of interest as a safeguard against chronic laboratory contamination. If a peak is observed within the retention time window of any analyte that would prevent the determination of that analyte, determine the source and eliminate it, if possible, before processing the samples. The blanks should be carried through all stages of sample preparation and analysis. When new reagents or chemicals are received, the lab should monitor the preparation and/or analysis blanks associated with samples for any signs of contamination. It is not necessary to test every new batch of reagents or chemicals prior to sample preparation if the source shows no prior problems. However, if reagents are changed during a preparation batch, separate blanks need to be prepared for each set of reagents.

9.6 Sample quality control for preparation and analysis

The laboratory must also have procedures for documenting the effect of the matrix on method performance (precision, accuracy, method sensitivity). At a minimum, this should include the analysis of QC samples including a method blank, a matrix spike, a duplicate, and a laboratory control sample (LCS) in each analytical batch and the addition of surrogates to each field sample and QC sample when surrogates are used. Any method blanks, matrix spike samples, and replicate samples should be subjected to the same analytical procedures (Sec. 11.0) as those used on actual samples.

9.6.1 Documenting the effect of the matrix should include the analysis of at least one matrix spike and one duplicate unspiked sample or one matrix spike/matrix spike duplicate pair. The decision on whether to prepare and analyze duplicate samples or a matrix spike/matrix spike duplicate must be based on a knowledge of the samples in the sample batch. If samples are expected to contain target analytes, laboratories may use a matrix spike and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes, then laboratories should use a matrix spike and matrix spike duplicate pair. Consult Method 8000 for information on developing acceptance criteria for the MS/MSD.

9.6.2 A laboratory control sample (LCS) should be included with each analytical batch. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS is spiked with the same analytes at the same concentrations as the matrix spike, when appropriate. When the results of the matrix spike analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix. Consult Method 8000 for information on developing acceptance criteria for the LCS.

9.6.3 Also see Method 8000 for the details on carrying out sample quality control procedures for preparation and analysis. In-house method performance criteria for

evaluating method performance should be developed using the guidance found in Method 8000.

9.7 Surrogate recoveries

If surrogates are used, the laboratory should evaluate surrogate recovery data from individual samples versus the surrogate control limits developed by the laboratory. See Method 8000 for information on evaluating surrogate data and developing and updating surrogate limits. Procedures for evaluating the recoveries of multiple surrogates and the associated corrective actions should be defined in an approved project plan.

9.8 The experience of the analyst performing GC/MS analyses is invaluable to the success of the methods. Each day that analysis is performed, the calibration verification standard should be evaluated to determine if the chromatographic system is operating properly. Questions that should be asked are: Do the peaks look normal? Is the response obtained comparable to the response from previous calibrations? Careful examination of the standard chromatogram can indicate whether the column is still performing acceptably, the injector is leaking, the injector septum needs replacing, etc. When any changes are made to the system (e.g., the column is changed, a septum is changed), see the guidance in Method 8000 regarding whether recalibration of the system must take place.

9.9 It is recommended that the laboratory adopt additional quality assurance practices for use with this method. The specific practices that are most productive depend upon the needs of the laboratory and the nature of the samples. Whenever possible, the laboratory should analyze standard reference materials and participate in relevant performance evaluation studies.

10.0 CALIBRATION AND STANDARDIZATION

See Sec 11.3 for information on calibration and standardization.

11.0 PROCEDURE

11.1 Sample preparation

11.1.1 Samples are normally prepared by one of the following methods prior to GC/MS analysis.

<u>Matrix</u>	<u>Methods</u>
Air (particulates and sorbent resin)	3542
Water (including TCLP leachates)	3510, 3520, 3535
Soil/sediment	3540, 3541, 3545, 3546, 3550, 3560, 3561
Waste	3540, 3541, 3545, 3546, 3550, 3560, 3561, 3580

11.1.2 In very limited applications, direct injection of the sample into the GC/MS system with a 10- μ L syringe may be appropriate. The quantitation limit is very high (approximately 10,000 μ g/L). Therefore, it is only appropriate where concentrations in excess of 10,000 μ g/L are expected.

11.2 Extract cleanup -- Cleanup procedures may not be necessary for a relatively clean sample matrix, but most extracts from environmental and waste samples will require additional preparation before analysis. The specific cleanup procedure used will depend on the nature of the sample to be analyzed and the data quality objectives for the measurements. General guidance for sample extract cleanup is provided in this section and in Method 3600.

Extracts may be cleaned up by any of the following methods prior to GC/MS analysis.

<u>Analytes of Interest</u>	<u>Methods</u>
Aniline and aniline derivatives	3620
Phenols	3630, 3640, 8041 ^a
Phthalate esters	3610, 3620, 3640
Nitrosamines	3610, 3620, 3640
Organochlorine pesticides	3610, 3620, 3630, 3640, 3660
PCBs	3620, 3630, 3660, 3665
Nitroaromatics and cyclic ketones	3620, 3640
Polynuclear aromatic hydrocarbons	3611, 3630, 3640
Haloethers	3620, 3640
Chlorinated hydrocarbons	3620, 3640
Organophosphorus pesticides	3620
Petroleum waste	3611, 3650
All base, neutral, and acid priority pollutants	3640

^a Method 8041 includes a derivatization technique and a GC/ECD analysis, if interferences are encountered on GC/FID.

11.3 Initial calibration

Establish the GC/MS operating conditions, using the following recommendations as guidance.

Mass range:	35-500 amu
Scan time:	# 1 sec/scan
Initial temperature:	40 EC, hold for 4 min
Temperature program:	40-320 EC at 10 EC/min
Final temperature:	320 EC, hold until 2 min after benzo[g,h,i]perylene elutes
Injector temperature:	250-300 EC
Transfer line temperature:	250-300 EC
Source temperature:	According to manufacturer's specifications
Injector:	Grob-type, splitless
Injection volume:	1-2 µL
Carrier gas:	Hydrogen at 50 cm/sec or helium at 30 cm/sec
Ion trap only:	Set axial modulation, manifold temperature, and emission current to manufacturer's recommendations

Split injection is allowed if the sensitivity of the mass spectrometer is sufficient.

11.3.1 The GC/MS system must be hardware-tuned such that injecting 50 ng or less of DFTPP meets the manufacturer's specified acceptance criteria or as listed in Table 3. The tuning criteria as outlined in Table 3 were developed using quadrupole mass spectrometer instrumentation and it is recognized that other tuning criteria may be more effective depending on the type of instrumentation, e.g., Time-of-Flight, Ion Trap, etc. In

these cases it would be appropriate to follow the manufacturer's tuning instructions or some other consistent tuning criteria. However, no matter which tuning criteria is selected, the system calibration must not begin until the tuning acceptance criteria are met with the sample analyses performed under the same conditions as the calibration standards.

11.3.1.1 In the absence of specific recommendations on how to acquire the mass spectrum of DFTPP from the instrument manufacturer, the following approach should be used: Three scans (the peak apex scan and the scans immediately preceding and following the apex) are acquired and averaged. Background subtraction is required, and must be accomplished using a single scan acquired within 20 scans of the elution of DFTPP. The background subtraction should be designed only to eliminate column bleed or instrument background ions. Do not subtract part of the DFTPP peak or any other discrete peak that does not coelute with DFTPP.

11.3.1.2 Use the DFTPP mass intensity criteria in the manufacturer's instructions as primary tuning acceptance criteria or those in Table 3 as default tuning acceptance criteria if the primary tuning criteria are not available. Alternatively, other documented tuning criteria may be used (e.g. CLP, or Method 625), provided that method performance is not adversely affected. The analyst is always free to choose criteria that are tighter than those included in this method or to use other documented criteria provided they are used consistently throughout the initial calibration, calibration verification, and sample analyses.

NOTE: All subsequent standards, samples, MS/MSDs, and blanks associated with a DFTPP analysis must use the identical mass spectrometer instrument conditions.

11.3.1.3 The GC/MS tuning standard solution should also be used to assess GC column performance and injection port inertness. Degradation of DDT to DDE and DDD should not exceed 20%. (See Method 8081 for the percent breakdown calculation.) Benzidine and pentachlorophenol should be present at their normal responses, and should not exceed a tailing factor of 2 given by the following equation:

$$\text{TailingFactor} = \frac{BC}{AB}$$

Where the peak is defined as follows: AC is the width at 10% height; DE is the height of peak and B is the height at 10% of DE. This equation compares the width of the back half of the peak to the width of the front half of the peak at 10% of the height. (See Figure 1 for an example tailing factor calculation.)

11.3.1.4 If degradation is excessive and/or poor chromatography is noted, the injection port may require cleaning. It may also be necessary to break off the first 6 to 12 in. of the capillary column. The use of a guard column (Sec. 6.1.6) between the injection port and the analytical column may help prolong analytical column performance life.

11.3.2 The internal standards selected in Sec. 7.5 should permit most of the components of interest in a chromatogram to have retention times of 0.80-1.20 relative to one of the internal standards. Use the base peak ion from the specific internal standard as the primary ion for quantitation (see Table 1). If interferences are noted, use the next most intense ion as the quantitation ion (e.g., for 1,4-dichlorobenzene- d_4 , use m/z 150 for quantitation).

11.3.3 Analyze 1-2 μL of each calibration standard (containing the compounds for quantitation and the appropriate surrogates and internal standards) and tabulate the area of the primary ion against concentration for each target analyte (as indicated in Table 1). A set of at least five calibration standards is necessary (see Sec. 7.7 and Method 8000). Alternate injection volumes may be used if the applicable quality control requirements for using this method are met. The injection volume must be the same for all standards and sample extracts. Figure 2 shows a chromatogram of a calibration standard containing base/neutral and acid analytes.

11.3.4 Initial calibration calculations

Calculate response factors (RFs) for each target analyte relative to one of the internal standards (see Table 5) as follows:

$$\text{RF} = \frac{A_s \times C_{is}}{A_{is} \times C_s}$$

where:

A_s = Peak area (or height) of the analyte or surrogate.

A_{is} = Peak area (or height) of the internal standard.

C_s = Concentration of the analyte or surrogate, in $\mu\text{g/L}$.

C_{is} = Concentration of the internal standard, in $\mu\text{g/L}$.

11.3.4.1 Calculate the mean response factor and the relative standard deviation (RSD) of the response factors for each target analyte using the following equations. The RSD should be less than or equal to 20% for each target analyte. It is also recommended that a minimum response factor for the most common target analytes, as noted in Table 4, be demonstrated for each individual calibration level as a means to ensure that these compounds are behaving as expected. In addition, meeting the minimum response factor criteria for the lowest calibration standard is critical in establishing and demonstrating the desired sensitivity. Due to the large number of compounds that may be analyzed by this method, some compounds will fail to meet this criteria. For these occasions, it is acknowledged that the failing compounds may not be critical to the specific project and therefore they may be used as qualified data or estimated values for screening purposes. The analyst should also strive to place more emphasis on meeting the calibration criteria for those compounds that are critical project compounds, rather than meeting the criteria for those less important compounds.

$$\text{mean RF} = \overline{RF} = \frac{\sum_{i=1}^n RF_i}{n}$$

$$SD = \sqrt{\frac{\sum_{i=1}^n (RF_i - \overline{RF})^2}{n-1}}$$

$$RSD = \frac{SD}{\overline{RF}} \times 100$$

where:

RF_i = RF for each of the calibration standards

\overline{RF} = mean RF for each compound from the initial calibration

n = Number of calibration standards, e.g., 5

11.3.4.2 If more than 10% of the compounds included with the initial calibration exceed the 20% RSD limit and do not meet the minimum correlation coefficient (0.99) for alternate curve fits, then the chromatographic system is considered too reactive for analysis to begin. Clean or replace the injector liner and/or capillary column, then repeat the calibration procedure beginning with Sec. 11.3.

11.3.5 Evaluation of retention times -- The relative retention time (RRT) of each target analyte in each calibration standard should agree within 0.06 RRT units. Late-eluting target analytes usually have much better agreement.

$$RRT = \frac{\text{Retention time of the analyte}}{\text{Retention time of the internal standard}}$$

11.3.6 Linearity of target analytes -- If the RSD of any target analyte is 20% or less, then the relative response factor is assumed to be constant over the calibration range, and the average relative response factor may be used for quantitation (Sec. 11.7.2).

11.3.6.1 If the RSD of any target analyte is greater than 20%, refer to Method 8000 for additional calibration options. One of the options must be applied to GC/MS calibration in this situation, or a new initial calibration must be performed. The average RF should not be used for compounds that have an RSD greater than 20% unless the concentration is reported as estimated.

11.3.6.2 When the RSD exceeds 20%, the plotting and visual inspection of a calibration curve can be a useful diagnostic tool. The inspection may indicate analytical problems, including errors in standard preparation, the presence of active sites in the chromatographic system, analytes that exhibit poor chromatographic behavior, etc.

11.3.6.3 Due to the large number of compounds that may be analyzed by this method, some compounds may fail to meet either the 20% RSD, minimum correlation coefficient criteria (0.99), or the acceptance criteria for alternative calibration procedures in Method 8000. Any calibration method described in Method 8000 may be used, but it should be used consistently. It is considered inappropriate once the calibration analyses are completed to select an alternative calibration procedure in order to pass the recommended criteria on a case-by-case basis. If compounds fail to meet these criteria, the associated concentrations may still be determined but they must be reported as estimated. In order to report non-detects, it must be demonstrated that there is adequate sensitivity to detect the failed compounds at the applicable lower quantitation limit.

11.4 GC/MS calibration verification -- Calibration verification consists of three steps that are performed at the beginning of each 12-hr analytical shift.

11.4.1 Prior to the analysis of samples or calibration standards, inject 50 ng or less of the DFTPP standard into the GC/MS system. The resultant mass spectrum for DFTPP must meet the criteria as outlined in Sec. 11.3.1 before sample analysis begins. These criteria must be demonstrated each 12-hr shift during which samples are analyzed.

11.4.2 The initial calibration function for each target analyte should be checked immediately after the first occurrence in the region of the middle of the calibration range with a standard from a source different from that used for the initial calibration. The value determined from the second source check should be within 30% of the expected concentration. An alternative recovery limit may be appropriate based on the desired project-specific data quality objectives. Quantitative sample analyses should not proceed for those analytes that fail the second source standard initial calibration verification. However, analyses may continue for those analytes that fail the criteria with an understanding these results could be used for screening purposes and would be considered estimated values.

11.4.3 The initial calibration (Sec. 11.3) for each compound of interest should be verified once every 12 hrs prior to sample analysis, using the introduction technique and conditions used for samples. This is accomplished by analyzing a calibration standard (containing all the compounds for quantitation) at a concentration either near the midpoint concentration for the calibrating range of the GC/MS or near the action level for the project. The results must be compared against the most recent initial calibration curve and should meet the verification acceptance criteria provided in Secs. 11.4.5 through 11.4.7.

NOTE: The DFTPP and calibration verification standard may be combined into a single standard as long as both tuning and calibration verification acceptance criteria for the project can be met without interferences.

11.4.4 A method blank should be analyzed prior to sample analyses in order to ensure that the total system (introduction device, transfer lines and GC/MS system) is free of contaminants. If the method blank indicates contamination, then it may be appropriate to analyze a solvent blank to demonstrate that the contamination is not a result of carryover from standards or samples. See Method 8000 for information regarding method blank performance criteria.

11.4.5 Calibration verification standard criteria

11.4.5.1 Each of the most common target analytes in the calibration verification standard should meet the minimum response factors as noted in Table 4. This criteria is particularly important when the common target analytes are also critical project-required compounds. This is the same check that is applied during the initial calibration.

11.4.5.2 If the minimum response factors are not met, the system should be evaluated, and corrective action should be taken before sample analysis begins. Possible problems include standard mixture degradation, injection port inlet contamination, contamination at the front end of the analytical column, and active sites in the column or chromatographic system.

11.4.5.3 All target compounds of interest must be evaluated using a 20% criterion. Use percent difference when performing the average response factor model calibration. Use percent drift when calibrating using a regression fit model. Refer to Method 8000 for guidance on calculating percent difference and drift.

11.4.5.4 If the percent difference or percent drift for a compound is less than or equal to 20%, then the initial calibration for that compound is assumed to be valid. Due to the large numbers of compounds that may be analyzed by this method, it is expected that some compounds will fail to meet the criterion. If the criterion is not met (i.e., greater than 20% difference or drift) for more than 20% of the compounds included in the initial calibration, then corrective action must be taken prior to the analysis of samples. In cases where compounds fail, they may still be reported as non-detects if it can be demonstrated that there was adequate sensitivity to detect the compound at the applicable quantitation limit. For situations when the failed compound is present, the concentrations must be reported as estimated values.

11.4.5.5 Problems similar to those listed under initial calibration could affect the ability to pass the calibration verification standard analysis. If the problem cannot be corrected by other measures, a new initial calibration must be generated. The calibration verification criteria must be met before sample analysis begins.

11.4.5.6 The method of linear regression analysis has the potential for a significant bias to the lower portion of a calibration curve, while the relative percent difference and quadratic methods of calibration do not have this potential bias. When calculating the calibration curves using the linear regression model, a minimum quantitation check on the viability of the lowest calibration point should be performed by re-fitting the response from the low concentration calibration standard back into the curve (see Method 8000 for additional details). It is not necessary to re-analyze a low concentration standard, rather the data system can recalculate the concentrations as if it were an unknown sample. The recalculated concentration of the low calibration point should be within $\pm 30\%$ of the standard's true concentration. Other recovery criteria may be applicable depending on the project's data quality objectives and for those situations the minimum quantitation check criteria should be outlined in a laboratory standard operating procedure, or a project-specific Quality Assurance Project Plan. Analytes which do not meet the minimum quantitation calibration re-fitting criteria should be considered "out of control" and corrective action such as redefining the lower limit of quantitation

and/or reporting those "out of control" target analytes as estimated when the concentration is at or near the lowest calibration point may be appropriate.

11.4.6 Internal standard retention time -- The retention times of the internal standards in the calibration verification standard must be evaluated immediately after or during data acquisition. If the retention time for any internal standard changes by more than 30 sec from that in the mid-point standard level of the most recent initial calibration sequence, then the chromatographic system must be inspected for malfunctions and corrections must be made, as required. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

11.4.7 Internal standard response -- If the EICP area for any of the internal standards in the calibration verification standard changes by a factor of two (-50% to +100%) from that in the mid-point standard level of the most recent initial calibration sequence, the mass spectrometer must be inspected for malfunctions and corrections must be made, as appropriate. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

11.5 GC/MS analysis of samples

11.5.1 It is highly recommended that sample extracts be screened on a GC/FID or GC/PID using the same type of capillary column used in the GC/MS system. This will minimize contamination of the GC/MS system from unexpectedly high concentrations of organic compounds.

11.5.2 Allow the sample extract to warm to room temperature. Just prior to analysis, add 10 μL of the internal standard solution to the 1 mL of concentrated sample extract obtained from sample preparation.

11.5.3 Inject an aliquot of the sample extract into the GC/MS system, using the same operating conditions that were used for the calibration (Sec. 11.3). The volume to be injected should include an appropriate concentration that is within the calibration range of base/neutral and acid surrogates using the surrogate solution as noted in Sec. 7.8. The injection volume must be the same volume that was used for the calibration standards.

11.5.4 If the response for any quantitation ion exceeds the initial calibration range of the GC/MS system, the sample extract must be diluted and reanalyzed. Additional internal standard solution must be added to the diluted extract to maintain the same concentration as in the calibration standards (usually 40 $\text{ng}/\mu\text{L}$, or other concentrations as appropriate, if a more sensitive GC/MS system is being used). Secondary ion quantitation should be used only when there are sample interferences with the primary ion.

NOTE: It may be a useful diagnostic tool to monitor internal standard retention times in all samples, spikes, blanks, and standards to effectively check drifting, method performance, poor injection execution, and anticipate the need for system inspection and/or maintenance. Internal standard responses (area counts) must be monitored in all samples, spikes, blanks for similar reasons. If the EICP area for any of the internal standards in samples, spikes and blanks changes by a factor of two (-50% to +100%) from the areas determined in the continuing calibration analyzed that day, corrective action must be taken. The samples, spikes or blanks should be reanalyzed or the data should be qualified.

11.5.4.1 When ions from a compound in the sample saturate the detector, this analysis should be followed by the analysis of an instrument blank consisting of clean solvent. If the blank analysis is not free of interferences, then the system must be decontaminated. Sample analysis may not resume until the blank analysis is demonstrated to be free of interferences. Contamination from one sample to the next on the instrument usually takes place in the syringe. If adequate syringe washes are employed, then carryover from high concentration samples can usually be avoided.

11.5.4.2 All dilutions should keep the response of the major constituents (previously saturated peaks) in the upper half of the linear range of the curve.

11.5.5 The use of selected ion monitoring (SIM) is acceptable for applications requiring quantitation limits below the normal range of electron impact mass spectrometry. However, SIM may provide a lesser degree of confidence in the compound identification, since less mass spectral information is available. Using the primary ion for quantitation and the secondary ions for confirmation set up the collection groups based on their retention times. The selected ions are nominal ions and most compounds have small mass defect, usually less than 0.2 amu, in their spectra. These mass defects should be used in the acquisition table. The dwell time may be automatically calculated by the laboratory's GC/MS software or manually calculated using the following formula. The total scan time should be less than 1,000 msec and produce at least 5 to 10 scans per chromatographic peak. The start and stop times for the SIM groups are determined from the full scan analysis using the formula below:

$$\text{Dwell Time for the Group} = \frac{\text{Scan Time (msec)}}{\text{Total Ions in the Group}}$$

Additional guidance for performing SIM analyses, in particular for PAHs and phenol target analyte compounds, can be found in the most recent CLP semivolatile organic methods statement of work (SOW). See the SIM sections from the following CLP SOW for further details: [EPA CLP Organics SOW](#). (Reference 14)

11.6 Analyte identification

11.6.1 The qualitative identification of compounds determined by this method is based on retention time and on comparison of the sample mass spectrum, after background correction, with characteristic ions in a reference mass spectrum. The reference mass spectrum must be generated by the laboratory using the conditions of this method. The characteristic ions from the reference mass spectrum are defined as the three ions of greatest relative intensity, or any ions over 30% relative intensity, if less than three such ions occur in the reference spectrum. Compounds are identified when the following criteria are met.

11.6.1.1 The intensities of the characteristic ions of a compound must maximize in the same scan or within one scan of each other. Selection of a peak by a data system target compound search routine where the search is based on the presence of a target chromatographic peak containing ions specific for the

target compound at a compound-specific retention time will be accepted as meeting this criterion.

11.6.1.2 The RRT of the sample component is within ± 0.06 RRT units of the RRT of the standard component.

11.6.1.3 The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum. (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%.) Use professional judgement in interpretation where interferences are observed.

11.6.1.4 Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 50% of the average of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. The resolution should be verified on the mid-point concentration of the initial calibration as well as the laboratory designated continuing calibration verification level if closely eluting isomers are to be reported (e.g., benzo(b)fluoranthene and benzo(k)fluoranthene).

11.6.1.5 Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e., a broadened peak with shoulder(s) or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important.

11.6.1.6 Examination of extracted ion current profiles of appropriate ions can aid in the selection of spectra and in qualitative identification of compounds. When analytes coelute (i.e., only one chromatographic peak is apparent), the identification criteria may be met, but each analyte spectrum will contain extraneous ions contributed by the coeluting compound.

11.6.2 For samples containing components not associated with the calibration standards, a library search may be made for the purpose of tentative identification. The necessity to perform this type of identification will be determined by the purpose of the analyses being conducted. Data system library search routines should not use normalization routines that would misrepresent the library or unknown spectra when compared to each other.

For example, the RCRA permit or waste delisting requirements may require the reporting of non-target analytes. Only after visual comparison of sample spectra with the nearest library searches may the analyst assign a tentative identification. Guidelines for tentative identification are:

- (1) Relative intensities of major ions in the reference spectrum (ions > 10% of the most abundant ion) should be present in the sample spectrum.
- (2) The relative intensities of the major ions should agree within $\pm 30\%$. (Example: For an ion with an abundance of 50% in the standard spectrum, the corresponding sample ion abundance must be between 20 and 80%.)

- (3) Molecular ions present in the reference spectrum should be present in the sample spectrum.
- (4) Ions present in the sample spectrum but not in the reference spectrum should be reviewed for possible background contamination or presence of coeluting compounds.
- (5) Ions present in the reference spectrum but not in the sample spectrum should be reviewed for possible subtraction from the sample spectrum because of background contamination or coeluting peaks. Data system library reduction programs can sometimes create these discrepancies.

11.7 Quantitation

11.7.1 Once a target compound has been identified, the quantitation of that compound will be based on the integrated abundance of the primary characteristic ion from the EICP.

11.7.1.1 It is highly recommended to use the integration produced by the software if the integration is correct because the software should produce more consistent integrations. However, manual integrations may be necessary when the software does not produce proper integrations because baseline selection is improper; the correct peak is missed; a coelution is integrated; the peak is partially integrated; etc. The analyst is responsible for ensuring that the integration is correct whether performed by the software or done manually.

11.7.1.2 Manual integrations should not be substituted for proper maintenance of the instrument or setup of the method (e.g. retention time updates, integration parameter files, etc). The analyst should seek to minimize manual integration by properly maintaining the instrument, updating retention times, and configuring peak integration parameters.

11.7.2 If the RSD of a compound's response factor is 20% or less, then the concentration in the extract may be determined using the average response factor (~~RF~~) from initial calibration data (Sec. 11.3.4). See Method 8000 for the equations describing internal standard calibration and either linear or non-linear calibrations.

11.7.3 Where applicable, the concentration of any non-target analytes identified in the sample (Sec. 11.6.2) should be estimated. The same formula as in Sec. 11.3.4 should be used with the following modifications: The areas A_x and A_{is} should be from the total ion chromatograms, and the RF for the compound should be assumed to be 1.

11.7.4 The resulting concentration should be reported indicating that the value is an estimate. Use the nearest internal standard free of interferences.

11.7.5 Quantitation of multicomponent compounds (e.g., Toxaphene, Aroclors, etc.) is beyond the scope of Method 8270. Normally, quantitation is performed using a GC/ECD, for example by using Methods 8081 or 8082. However, this method (8270) may be used to confirm the identification of these compounds, when the concentrations are at least 10 ng/ μ L in the concentrated sample extract.

11.7.6 Quantitation of multicomponent parameters such as diesel range organics (DROs) and total petroleum hydrocarbons (TPH) using the Method 8270 recommended internal standard quantitation technique is beyond the scope of this method. Typically,

analyses for these parameters are performed using GC/FID or GC with a MS detector capability that is available with Method 8015.

11.7.7 Structural isomers that produce very similar mass spectra should be quantitated as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 50% of the average of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs. The resolution should be verified on the mid-point concentration of the initial calibration as well as the laboratory designated continuing calibration verification level if closely eluting isomers are to be reported (e.g., benzo(b)fluoranthene and benzo(k)fluoranthene).

12.0 DATA ANALYSIS AND CALCULATIONS

See Sec. 11.7 and Method 8000 for information on data analysis and calculations.

13.0 METHOD PERFORMANCE

13.1 Performance data and related information are provided in SW-846 methods only as examples and guidance. The data do not represent required performance criteria for users of the methods. Instead, performance criteria should be developed on a project-specific basis, and the laboratory should establish in-house QC performance criteria for the application of this method. These performance data are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

13.2 Single laboratory initial demonstration of capability data were generated from five replicate measurements using a modified continuous liquid-liquid extractor (Method 3520) with hydrophobic membrane. In this case only a single acid pH extraction was performed using the CLP calibration criteria and the applicable CLP target analytes. These data are presented in Table 6. Laboratories should generate their own acceptance criteria depending on the extraction and instrument conditions. (See Method 8000.)

13.3 Chromatograms from calibration standards analyzed with Day 0 and Day 7 samples were compared to detect possible deterioration of GC performance. These recoveries (using Method 3510 extraction) are presented in Table 7. These data are provided for guidance purposes only.

13.4 Method performance data using Method 3541 (automated Soxhlet extraction) are presented in Tables 8 and 9. Single laboratory accuracy and precision data were obtained for semivolatiles organics in a clay soil by spiking at a concentration of 6 mg/kg for each compound. The spiking solution was mixed into the soil during addition and then allowed to equilibrate for approximately 1 hour prior to extraction. The spiked samples were then extracted by Method 3541 (Automated Soxhlet). Three extractions were performed and each extract was analyzed by gas chromatography/mass spectrometry following Method 8270. The low recovery of the more volatile compounds is probably due to volatilization losses during equilibration. These data as listed were taken from Reference 7 and are provided for guidance purposes only.

13.5 Surrogate precision and accuracy data are presented in Table 10 from a field dynamic spiking study based on air sampling by Method 0010. The trapping media were prepared for analysis by Method 3542 and subsequently analyzed by this method (8270). These data are provided for guidance purposes only.

13.6 Single laboratory precision and bias data using Method 3545 (pressurized fluid extraction) for semivolatile organic compounds are presented in Table 11. The samples were conditioned spiked samples prepared and certified by a commercial supplier that contained 57 semivolatile organics at three concentrations (250, 2500, and 12,500 µg/kg) on three types of soil (clay, loam and sand). Spiked samples were extracted both by the Dionex Accelerated Solvent Extraction system and by the Perstorp Environmental Soxtec™ (automated Soxhlet). The data in Table 11 represent seven replicate extractions and analyses for each individual sample and were taken from Reference 9. The average recoveries from the three matrices for all analytes and all replicates relative to the automated Soxhlet data are as follows: clay 96.8%, loam 98.7% and sand 102.1%. The average recoveries from the three concentrations also relative to the automated Soxhlet data are as follows: low - 101.2%, mid - 97.2% and high - 99.2%. These data are provided for guidance purposes only.

13.7 Single laboratory precision and bias data using Method 3561 (SFE extraction of PAHs with a variable restrictor and solid trapping material) were obtained for the method analytes by the extraction of two certified reference materials (EC-1, a lake sediment from Environment Canada and HS-3, a marine sediment from the National Science and Engineering Research Council of Canada, both naturally-contaminated with PAHs). The SFE instrument used for these extractions was a Hewlett-Packard Model 7680. Analysis was by GC/MS. Average recoveries from six replicate extractions range from 85 to 148% (overall average of 100%) based on the certified value (or a Soxhlet value if a certified value was unavailable for a specific analyte) for the lake sediment. Average recoveries from three replicate extractions range from 73 to 133% (overall average of 92%) based on the certified value for the marine sediment. The data are found in Tables 12 and 13 and were taken from Reference 10. These data are provided for guidance purposes only.

13.8 Single laboratory precision and accuracy data using Method 3561 (SFE extraction of PAHs with a fixed restrictor and liquid trapping) were obtained for twelve of the method analytes by the extraction of a certified reference material (a soil naturally contaminated with PAHs). The SFE instrument used for these extractions was a Dionex Model 703-M. Analysis was by GC/MS. Average recoveries from four replicate extractions range from 60 to 122% (overall average of 89%) based on the certified value. The instrument conditions that were utilized to extract a 3.4 g sample were as follows: Pressure -- 300 atm; time -- 60 min.; extraction fluid -- CO₂; modifier -- 10% 1:1 (v/v) methanol/methylene chloride; Oven temperature -- 80 °C; Restrictor temperature -- 120 °C; and, trapping fluid -- chloroform (methylene chloride has also been used). The data are found in Table 14 and were taken from Reference 11. These data are provided for guidance purposes only.

13.9 Tables 15 and 16 contain single-laboratory precision and accuracy data for solid-phase extraction of TCLP buffer solutions spiked at two levels and extracted using Method 3535. These data are provided for guidance purposes only.

13.10 Table 17 contains multiple-laboratory data for solid-phase extraction of spiked TCLP soil leachates extracted using Method 3535. These data are provided for guidance purposes only.

13.11 Tables 18 through 22 contain single-laboratory PAH recovery data for microwave extraction of contaminated soils and standard reference materials using Method 3546. These data are provided for guidance purposes only.

14.0 POLLUTION PREVENTION

14.1 Pollution prevention encompasses any technique that reduces or eliminates the quantity and/or toxicity of waste at the point of generation. Numerous opportunities for pollution prevention exist in laboratory operations. The EPA has established a preferred hierarchy of environmental management techniques that places pollution prevention as the management option of first choice. Whenever feasible, laboratory personnel should use pollution prevention techniques to address their waste generation. When wastes cannot be feasibly reduced at the source, the Agency recommends recycling as the next best option.

14.2 For information about pollution prevention that may be applicable to laboratories and research institutions consult *Less is Better: Laboratory Chemical Management for Waste Reduction* available from the American Chemical Society's Department of Government Relations and Science Policy, 1155 16th St., N.W. Washington, D.C. 20036, <http://www.acs.org>.

15.0 WASTE MANAGEMENT

The Environmental Protection Agency requires that laboratory waste management practices be conducted consistent with all applicable rules and regulations. The Agency urges laboratories to protect the air, water, and land by minimizing and controlling all releases from hoods and bench operations, complying with the letter and spirit of any sewer discharge permits and regulations, and by complying with all solid and hazardous waste regulations, particularly the hazardous waste identification rules and land disposal restrictions. For further information on waste management, consult *The Waste Management Manual for Laboratory Personnel* available from the American Chemical Society at the address listed in Sec. 14.2.

TABLE 2
(continued)

- ^a Sample lower limits of quantitation are highly matrix-dependent and those listed here are provided for guidance and may not always be achievable.
- ^b Lower limits of quantitation listed for soil/sediment are based on wet weight. When data are reported on a dry weight basis, the lower limits will be higher based on the % dry weight of each sample. These lower limits are based on a 30-g sample and gel permeation chromatography cleanup.

ND = Not Determined

NA = Not Applicable

Other Matrices

Factor^c

High-concentration soil and sludges by ultrasonic extractor
Non-water miscible waste

7.5
75

^cLower limit of quantitation = (Lower limit of quantitation for low soil/sediment given above in Table 2) x (Factor)

TABLE 3

DFTPP KEY IONS AND ION ABUNDANCE CRITERIA^{a,b}

Mass	Ion Abundance Criteria
51	10-80% of Base Peak
68	< 2% of mass 69
70	< 2% of mass 69
127	10-80% of Base Peak
197	< 2% of mass 198
198	Base peak, or > 50% of Mass 442
199	5-9% of mass 198
275	10-60% of Base Peak
365	> 1% of mass 198
441	present but < 24% of mass 442
442	Base Peak, or > 50% of mass 198
443	15-24% of mass 442

^a The majority of the data are taken from Reference 13 (Method 525.2).

^b The criteria in this table are intended to be used as default criteria for quadrupole instrumentation if optimized manufacturer's operating conditions are not available. Alternate tuning criteria may be employed (e.g., CLP or Method 625), provided that method performance is not adversely affected. See Sec. 11.3.1

\bar{x} = Average recovery for five initial demonstration of capability measurements, in µg/L

^a Extraction using acidic pH only with a modified continuous liquid-liquid extractor with hydrophobic membrane according to Method 3520. These values are for guidance only. Appropriate derivation of acceptance criteria for similar extraction conditions may result in much different recovery ranges. See Method 8000 for information on developing and updating acceptance criteria for method performance.

Benzo(e)pyrene	87,610	3.9	N/R
Benzo(a)pyrene	128,330	3.9	110,000
Perylene	35,260	4.3	N/R
Indeno(123-cd)pyrene	63,900	5.0	25,000
Dibenz(a,h)anthracene	17,290	6.9	N/R
Benzo(ghi)perylene	42,720	6.9	20,000

*n = 4

Soil samples obtained from US EPA Emergency Response Center archive bank through their contract laboratory REAC (Edison, NJ). The standard Soxhlet extraction procedures were performed by REAC three years earlier; this long storage period is believed to account for the low naphthalene recovery data in the present study

REAC data labeled N/R = not reported

TABLE 19

SINGLE-LABORATORY PAH RECOVERY DATA FROM HS-5 MARINE SEDIMENT MATERIALS, USING METHOD 3546 (MICROWAVE EXTRACTION)

Compound	Certified Value (µg/kg)	Confidence Interval (µg/kg)	Recovery (%)

TABLE 22

SINGLE-LABORATORY PAH RECOVERY DATA FROM SRM 1941 MARINE SEDIMENT,
USING METHOD 3546 (MICROWAVE EXTRACTION)

Compound	Certified Value ($\mu\text{g}/\text{kg}$)	Recovery (%)
Naphthalene	1010	97.4
Fluorene	100	100.0
Phenanthrene	490	102.0
Fluoranthene	980	116.7
Pyrene	810	97.3
Benz(a)anthracene	430	89.8
Chrysene	380	130.3
Benzo(b)fluoranthene	740	95.8
Benzo(k)fluoranthene	360	130.2
Benz(e)pyrene	550	81.0
Benzo(a)pyrene	630	76.0
Perylene	450	72.4
Indeno(123-cd)pyrene	500	126.0
Dibenz(a,h)anthracene	110	78.7
Benz(ghi)perylene	530	85.2

n = 3

All RSDs < 10%

FIGURE 1
TAILING FACTOR CALCULATION

Example calculation: Peak Height = DE = 100 mm
10% Peak Height = BD = 10 mm
Peak Width at 10% Peak Height = AC = 23 mm
AB = 11 mm
BC = 12 mm

Therefore: Tailing Factor = $\frac{12}{11} = 1.1$

FIGURE 2
GAS CHROMATOGRAM OF BASE/NEUTRAL AND ACID CALIBRATION STANDARD

No. L-9

Semivolatile Organics SIM

SW-846 Method 8270D

METHOD 8270D

SEMIVOLATILE ORGANIC COMPOUNDS BY GAS CHROMATOGRAPHY/MASS SPECTROMETRY (GC/MS)

SW-846 is not intended to be an analytical training manual. Therefore, method procedures are written based on the assumption that they will be performed by analysts who are formally trained in at least the basic principles of chemical analysis and in the use of the subject technology.

In addition, SW-846 methods, with the exception of required method use for the analysis of method-defined parameters, are intended to be guidance methods which contain general information on how to perform an analytical procedure or technique which a laboratory can use as a basic starting point for generating its own detailed Standard Operating Procedure (SOP), either for its own general use or for a specific project application. The performance data included in this method are for guidance purposes only, and are not intended to be and must not be used as absolute QC acceptance criteria for purposes of laboratory accreditation.

1.0 SCOPE AND APPLICATION

1.1 This method is used to determine the concentration of semivolatile organic compounds in extracts prepared from many types of solid waste matrices, soils, air sampling media and water samples. Direct injection of a sample may be used in limited applications. The following RCRA analytes have been determined by this method:

Compounds	CAS No ^a	Appropriate Preparation Techniques ^b				
		3510	3520	3540/ 3541	3550	3580
Acenaphthene	83-32-9	X	X	X	X	X

KEY TO ANALYTE LIST

- AW = Adsorption to walls of glassware during extraction and storage.
- CP = Nonreproducible chromatographic performance.
- DC = Unfavorable distribution coefficient.
- HE = Hydrolysis during extraction accelerated by acidic or basic conditions.
- HS = Hydrolysis during storage potential.
- LR = Low response.
- ND = Not determined.
- OE = Oxidation during extraction accelerated by basic conditions.
- OS = Oxidation during storage potential.
- X = Historically, adequate recovery can be obtained by this technique. However, actual recoveries may vary depending on the extraction efficiency, the number of constituents being analyzed concurrently, and the analytical instrumentation.

1.2 In addition to the sample preparation methods listed in the above analyte list, Method 3535 describes a solid-phase extraction procedure that may be applied to the extraction of semivolatiles from TCLP leachates (see Tables 16 and 17 of this method for performance data). Method 3542 describes sample preparation for semivolatile organic compounds in air sampled by Method 0010 (see Table 11 of this method for surrogate performance data), Method 3545 describes an automated solvent extraction device for semivolatiles in solids (see Table 12 of this method for performance data), Method 3561 describes a supercritical fluid device for the extraction of PAHs from solids (see Tables 13, 14, and 15 of this method for performance data), and Method 3546 provides an extraction procedure employing commercially available microwave equipment to extract semivolatiles while using less solvent and taking less time than procedures such as a Soxhlet extraction (see Tables 19 through 23 of this method for the applicable performance data). (The tabulated data are provided for guidance purposes only.)

1.3 This method can be used to quantitate most neutral, acidic, and basic organic compounds that are soluble in methylene chloride (or other suitable solvents provided that the desired performance data can be generated) and are capable of being eluted, without derivatization, as sharp peaks from a gas chromatographic fused-silica capillary column coated with a slightly polar silicone. Such compounds include polynuclear aromatic hydrocarbons, chlorinated hydrocarbons and pesticides, phthalate esters, organophosphate esters, nitrosamines, haloethers, aldehydes, ethers, ketones, anilines, pyridines, quinolines, aromatic

nitro compounds, and phenols, including nitrophenols. See Table 1 for a list of compounds and their characteristic ions that have been evaluated.

In most cases, this method is not appropriate for the quantitation of multicomponent analytes, e.g., Aroclors, Toxaphene, Chlordane, etc., because of limited sensitivity for those analytes. When these analytes have been identified by another technique, Method 8270 may be appropriate for confirmation of the identification of these analytes when concentration in the extract permits. Refer to Methods 8081 and 8082 for guidance on calibration and quantitation of multicomponent analytes such as the Aroclors, Toxaphene, and Chlordane.

1.4 The following compounds may require special treatment when being determined by this method:

1.4.1 Benzidine may be subject to oxidative losses during solvent concentration and its chromatographic behavior is poor.

1.4.2 Under the alkaline conditions of the extraction step from aqueous matrices, α -BHC, γ -BHC, Endosulfan I and II, and Endrin are subject to decomposition. Neutral extraction should be performed if these compounds are expected to be present.

1.4.3 Hexachlorocyclopentadiene is subject to thermal decomposition in the inlet of the gas chromatograph, chemical reaction in acetone solution, and photochemical decomposition.

1.4.4 N-nitrosodimethylamine is difficult to separate from the solvent under the chromatographic conditions described.

1.4.5 N-nitrosodiphenylamine decomposes in the gas chromatographic inlet and cannot be separated from diphenylamine. For this reason, it is acceptable to report the combined result for n-nitrosodiphenylamine and diphenylamine for either of these compounds as a combined concentration.

1.4.6 1,2-Diphenylhydrazine is unstable even at room temperature and readily converts to azobenzene. Given the stability problems, it would be acceptable to calibrate for 1,2-diphenylhydrazine using azobenzene. Under these poor compound separation circumstances the results for either of these compounds should be reported as a combined concentration.

1.4.7 Pentachlorophenol, 2,4-dinitrophenol, 4-nitrophenol, benzoic acid, 4,6-dinitro-2-methylphenol, 4-chloro-3-methylphenol, 2-nitroaniline, 3-nitroaniline, 4-nitroaniline, and benzyl alcohol are subject to erratic chromatographic behavior, especially if the GC system is contaminated with high boiling material.

1.4.8 Pyridine may perform poorly at the GC injection port temperatures listed in this method. Lowering the injection port temperature may reduce the amount of degradation. However, the analyst must use caution in modifying the injection port temperature, as the performance of other analytes may be adversely affected. Therefore, if pyridine is to be determined in addition to other target analytes, it may be necessary to perform separate analyses. In addition, pyridine may be lost during the evaporative concentration of the sample extract. As a result, many of the extraction methods listed above may yield low recoveries unless great care is exercised during the concentration steps. For this reason, analysts may wish to consider the use of extraction techniques such as pressurized fluid extraction (Method 3545), microwave extraction (Method 3546),

or supercritical fluid extraction, which involve smaller extract volumes, thereby reducing or eliminating the need for evaporative concentration techniques for many applications.

1.4.9 Toluene diisocyanate rapidly hydrolyzes in water (half-life of less than 30 min). Therefore, recoveries of this compound from aqueous matrices should not be expected. In addition, in solid matrices, toluene diisocyanate often reacts with alcohols and amines to produce urethane and ureas and consequently cannot usually coexist in a solution containing these materials.

1.4.10 In addition, analytes in the list provided above are flagged when there are limitations caused by sample preparation and/or chromatographic problems.

1.5 The lower limits of quantitation for this method when determining an individual compound are approximately 660 µg/kg (wet weight) for soil/sediment samples, 1-200 mg/kg for wastes (dependent on matrix and method of preparation), and 10 µg/L for ground water samples (see Table 2). Lower limits of quantitation will be proportionately higher for sample extracts that require dilution to avoid saturation of the detector. The lower limits of quantitation listed in Table 2 are provided for guidance and may not always be achievable.

1.6 Prior to employing this method, analysts are advised to consult the base method for each type of procedure that may be employed in the overall analysis (e.g., Methods 3500, 3600, 5000, and 8000) for additional information on quality control procedures, development of QC acceptance criteria, calculations, and general guidance. Analysts also should consult the disclaimer statement at the front of the manual and the information in Chapter Two for guidance on the intended flexibility in the choice of methods, apparatus, materials, reagents, and supplies, and on the responsibilities of the analyst for demonstrating that the techniques employed are appropriate for the analytes of interest, in the matrix of interest, and at the levels of concern.

In addition, analysts and data users are advised that, except where explicitly specified in a regulation, the use of SW-846 methods is *not* mandatory in response to Federal testing requirements. The information contained in this method is provided by EPA as guidance to be used by the analyst and the regulated community in making judgments necessary to generate results that meet the data quality objectives for the intended application.

1.7 Use of this method is restricted to use by, or under supervision of, personnel appropriately experienced and trained in the use of gas chromatograph/mass spectrometers and skilled in the interpretation of mass spectra. Each analyst must demonstrate the ability to generate acceptable results with this method.

2.0 SUMMARY OF METHOD

2.1 The samples are prepared for analysis by gas chromatography/mass spectrometry (GC/MS) using the appropriate sample preparation (refer to Method 3500) and, if necessary, sample cleanup procedures (refer to Method 3600).

2.2 The semivolatile compounds are introduced into the GC/MS by injecting the sample extract into a gas chromatograph (GC) equipped with a narrow-bore fused-silica capillary column. The GC column is temperature-programmed to separate the analytes, which are then detected with a mass spectrometer (MS) connected to the gas chromatograph.

2.3 Analytes eluted from the capillary column are introduced into the mass spectrometer via a jet separator or a direct connection. Identification of target analytes is

accomplished by comparing their mass spectra with the electron impact (or electron impact-like) spectra of authentic standards. Quantitation is accomplished by comparing the response of a major (quantitation) ion relative to an internal standard using an appropriate calibration curve for the intended application.

2.4 This method includes specific calibration and quality control steps that supersede the general recommendations provided in Method 8000.

3.0 DEFINITIONS

Refer to Chapter One and the manufacturer's instructions for definitions that may be relevant to this procedure.

4.0 INTERFERENCES

4.1 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All of these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks. Specific selection of reagents and purification of solvents by distillation in all-glass systems may be necessary. Refer to each method to be used for specific guidance on quality control procedures and to Chapter Four for general guidance on the cleaning of glassware. Also refer to Method 8000 for a discussion of interferences.

4.2 Raw GC/MS data from all blanks, samples, and spikes must be evaluated for interferences. Determine if the source of interference is in the preparation and/or cleanup of the samples and take corrective action to eliminate the problem.

4.3 Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed. To reduce carryover, the sample syringe must be rinsed with solvent between sample injections. Whenever an unusually concentrated sample is encountered, it should be followed by the analysis of solvent to check for cross-contamination.

5.0 SAFETY

This method does not address all safety issues associated with its use. The laboratory is responsible for maintaining a safe work environment and a current awareness file of OSHA regulations regarding the safe handling of the chemicals listed in this method. A reference file of material safety data sheets (MSDSs) should be available to all personnel involved in these analyses.

6.0 EQUIPMENT AND SUPPLIES

The mention of trade names or commercial products in this manual is for illustrative purposes only, and does not constitute an EPA endorsement or exclusive recommendation for use. The products and instrument settings cited in SW-846 methods represent those products and settings used during method development or subsequently evaluated by the Agency. Glassware, reagents, supplies, equipment, and settings other than those listed in this manual may be employed provided that method performance appropriate for the intended application has been demonstrated and documented.

This section does not list common laboratory glassware (e.g., beakers and flasks).

6.1 Gas chromatograph/mass spectrometer system

6.1.1 Gas chromatograph -- An analytical system equipped with a temperature-programmable gas chromatograph suitable for splitless injection and all required accessories, including syringes, analytical columns, and gases. The capillary column should be directly coupled to the source.

6.1.2 Column -- 30-m x 0.25-mm ID (or 0.32-mm ID) 0.25, 0.5, or 1- μ m film thickness silicone-coated fused-silica capillary column (J&W Scientific DB-5 or equivalent). The columns listed in this section were the columns used in developing the method. The listing of these columns in this method is not intended to exclude the use of other columns that may be developed. Laboratories may use these columns or other capillary columns provided that the laboratories document method performance data (e.g., chromatographic resolution, analyte breakdown, and sensitivity) that are appropriate for the intended application.

6.1.3 Mass spectrometer

6.1.3.1 Capable of scanning from 35 to 500 amu every 1 sec or less, using 70 volts (nominal) electron energy in the electron impact ionization mode. The mass spectrometer must be capable of producing a mass spectrum for decafluorotriphenylphosphine (DFTPP) which meets the criteria as outlined in Sec. 11.3.1.

6.1.3.2 An ion trap mass spectrometer may be used if it is capable of axial modulation to reduce ion-molecule reactions and can produce electron impact-like spectra that match those in the EPA/NIST Library. The mass spectrometer must be capable of producing a mass spectrum for DFTPP which meets the criteria as outlined in Sec. 11.3.1

6.1.4 GC/MS interface -- Any GC-to-MS interface may be used that gives acceptable calibration points for each compound of interest and achieves acceptable tuning performance criteria. For a narrow-bore capillary column, the interface is usually capillary-direct into the mass spectrometer source.

6.1.5 Data system -- A computer system should be interfaced to the mass spectrometer. The system must allow the continuous acquisition and storage on machine-readable media of all mass spectra obtained throughout the duration of the chromatographic program. The computer should have software that can search any GC/MS data file for ions of a specific mass and that can plot such ion abundances versus time or scan number. This type of plot is defined as an Extracted Ion Current Profile (EICP). Software should also be available that allows integrating the abundances in any EICP between specified time or scan-number limits. The most recent version of the EPA/NIST Mass Spectral Library should also be available.

6.1.6 Guard column (optional) -- (J&W deactivated fused-silica, 0.25-mm ID x 6-m, or equivalent) between the injection port and the analytical column joined with column connectors (Agilent Catalog No. 5062-3556, or equivalent).

6.2 Syringe -- 10- μ L.

- 6.3 Volumetric flasks, Class A -- Appropriate sizes equipped with ground-glass stoppers.
- 6.4 Balance -- Analytical, capable of weighing 0.0001 g.
- 6.5 Bottles -- Glass equipped with polytetrafluoroethylene (PTFE)-lined screw caps or crimp tops.

7.0 REAGENTS AND STANDARDS

7.1 Reagent-grade chemicals must be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. Reagents should be stored in glass to prevent the leaching of contaminants from plastic containers.

7.2 Organic-free reagent water -- All references to water in this method refer to organic-free reagent water.

7.3 Standard solutions

The following sections describe the preparation of stock, intermediate, and working standards for the compounds of interest. This discussion is provided as an example, and other approaches and concentrations of the target compounds may be used, as appropriate for the intended application. See Method 8000 for additional information on the preparation of calibration standards.

7.4 Stock standard solutions (1000 mg/L) -- Standard solutions can be prepared from pure standard materials or purchased as certified solutions.

7.4.1 Prepare stock standard solutions by accurately weighing about 0.0100 g of pure material. Dissolve the material in pesticide quality acetone or other suitable solvent and dilute to volume in a 10-mL volumetric flask. Larger volumes can be used at the convenience of the analyst. When compound purity is assayed to be 96% or greater, the weight may be used without correction to calculate the concentration of the stock standard. Commercially-prepared stock standards may be used at any concentration if they are certified by the manufacturer or by an independent source.

7.4.2 Transfer the stock standard solutions into bottles equipped with PTFE-lined screw-caps. Store, protected from light, at #6 EC or as recommended by the standard manufacturer. Stock standard solutions should be checked frequently for signs of degradation or evaporation, especially just prior to preparing calibration standards from them.

7.4.3 Stock standard solutions must be replaced after 1 year or sooner if comparison with quality control check samples indicates a problem.

7.4.4 It is recommended that nitrosamine compounds be placed together in a separate calibration mix and not combined with other calibration mixes. When using a premixed certified standard, consult the manufacturer's instructions for additional guidance.

7.4.5 Mixes with hydrochloride salts may contain hydrochloric acid, which can cause analytical difficulties. When using a premixed certified standard, consult the manufacturer's instructions for additional guidance.

7.5 Internal standard solutions -- The internal standards recommended are 1,4-dichlorobenzene- d_4 , naphthalene- d_8 , acenaphthene- d_{10} , phenanthrene- d_{10} , chrysene- d_{12} , and perylene- d_{12} (see Table 5). Other compounds may be used as internal standards as long as the criteria in Sec. 11.3.2 are met.

7.5.1 Dissolve 0.200 g of each compound with a small volume of carbon disulfide. Transfer to a 50-mL volumetric flask and dilute to volume with methylene chloride so that the final solvent is approximately 20% carbon disulfide. Most of the compounds are also soluble in small volumes of methanol, acetone, or toluene, except for perylene- d_{12} . The resulting solution will contain each standard at a concentration of 4,000 ng/ μ L. Each 1-mL sample extract undergoing analysis should be spiked with 10 μ L of the internal standard solution, resulting in a concentration of 40 ng/ μ L of each internal standard. Store away from any light source at #6 EC when not in use (-10 EC is recommended). When using premixed certified solutions, store according to the manufacturer's documented holding time and storage temperature recommendations.

7.5.2 If a more sensitive mass spectrometer is employed to achieve lower quantitation levels, a more dilute internal standard solution may be required. Area counts of the internal standard peaks should be between 50-200% of the area of the target analytes in the mid-point calibration analysis.

7.6 GC/MS tuning standard -- A methylene chloride solution containing 50 ng/ μ L of decafluorotriphenylphosphine (DFTPP) should be prepared. The standard should also contain 50 ng/ μ L each of 4,4'-DDT, pentachlorophenol, and benzidine to verify injection port inertness and GC column performance. Alternate concentrations may be used to compensate for different injection volumes if the total amount injected is 50 ng or less. Store away from any light source at #6 EC when not in use (-10 EC is recommended). If a more sensitive mass spectrometer is employed to achieve lower quantitation levels, a more dilute tuning solution may be necessary. When using premixed certified solutions, store according to the manufacturer's documented holding time and storage temperature recommendations.

7.7 Calibration standards -- A minimum of five calibration standards should be prepared at different concentrations. At least one of the calibration standards should correspond to a sample concentration at or below that necessary to meet the data quality objectives of the project. The remaining standards should correspond to the range of concentrations found in actual samples but should not exceed the working range of the GC/MS system. Each standard and/or series of calibration standards prepared at a given concentration should contain all the desired project-specific target analytes for which quantitation and quantitative results are to be reported by this method.

7.7.1 It is the intent of EPA that all target analytes for a particular analysis be included in the calibration standard(s). These target analytes may not include the entire list of analytes (Sec. 1.1) for which the method has been demonstrated. However, the laboratory shall not report a quantitative result for a target analyte that was not included in the calibration standard(s).

7.7.2 Each 1-mL aliquot of calibration standard should be spiked with 10 μ L of the internal standard solution prior to analysis. All standards should be stored away from any light source at #6 EC when not in use (-10 EC is recommended), and should be freshly prepared once a year, or sooner if check standards indicate a problem. The calibration

verification standard should be prepared, as necessary, and stored at #6 EC. When using premixed certified solutions, store according to the manufacturer's documented holding time and storage temperature recommendations.

7.8 Surrogate standards -- The recommended surrogates are phenol- d_6 , 2-fluorophenol, 2,4,6-tribromophenol, nitrobenzene- d_5 , 2-fluorobiphenyl, and p-terphenyl- d_{14} . See Method 3500 for instructions on preparing the surrogate solutions.

NOTE: In the presence of samples containing residual chlorine, phenol- d_6 has been known to react to form chlorinated phenolic compounds that are not detected as the original spiked surrogate. Sample preservation precautions outlined in Chapter Four should be used when residual chlorine is known to be present in order to minimize degradation of deuterated phenols or any other susceptible target analyte.

7.8.1 Surrogate standard check -- Determine what the appropriate concentration should be for the blank extracts after all extraction, cleanup, and concentration steps. Inject this concentration into the GC/MS to determine recovery of surrogate standards. It is recommended that this check be done whenever a new surrogate spiking solution is prepared.

NOTE: Method 3561 (SFE Extraction of PAHs) recommends the use of bromobenzene and p-quaterphenyl to better cover the range of PAHs listed in the method.

7.8.2 If a more sensitive mass spectrometer is employed to achieve lower quantitation levels, a more dilute surrogate solution may be necessary.

7.9 Matrix spike and laboratory control standards -- See Method 3500 for instructions on preparing the matrix spike standard. The same standard may be used as the laboratory control standard (LCS) and the spiking solution should be the same source as used for the initial calibration standards to restrict the influence of standard accuracy on the determination of recovery through preparation and analysis.

7.9.1 Matrix spike check -- Determine what concentration should be in the blank extracts after all extraction, cleanup, and concentration steps. Inject this concentration into the GC/MS to determine recovery. It is recommended that this check be done whenever a new matrix spiking solution is prepared.

7.9.2 If a more sensitive mass spectrometer is employed to achieve lower quantitation levels, a more dilute matrix and LCS spiking solution may be necessary.

7.9.3 Some projects may require the spiking of the specific compounds of interest, since the spiking compounds listed in Method 3500 would not be representative of the compounds of interest required for the project. When this occurs, the matrix and LCS spiking standards should be prepared in methanol, with each compound present at a concentration appropriate for the project.

7.10 Solvents -- Acetone, hexane, methylene chloride, isooctane, carbon disulfide, toluene, and other appropriate solvents. All solvents should be pesticide quality or equivalent. Solvents may be degassed prior to use.

8.0 SAMPLE COLLECTION, PRESERVATION, AND STORAGE

8.1 See the introductory material to Chapter Four, "Organic Analytes."

8.2 Store the sample extracts at #6 EC, protected from light, in sealed vials (e.g., screw-cap vials or crimp-capped vials) equipped with unpierced PTFE-lined septa.

9.0 QUALITY CONTROL

9.1 Refer to Chapter One for guidance on quality assurance (QA) and quality control (QC) protocols. When inconsistencies exist between QC guidelines, method-specific QC criteria take precedence over both technique-specific criteria and those criteria given in Chapter One, and technique-specific QC criteria take precedence over the criteria in Chapter One. Any effort involving the collection of analytical data should include development of a structured and systematic planning document, such as a Quality Assurance Project Plan (QAPP) or a Sampling and Analysis Plan (SAP), which translates project objectives and specifications into directions for those that will implement the project and assess the results. Each laboratory should maintain a formal quality assurance program. The laboratory should also maintain records to document the quality of the data generated. All data sheets and quality control data should be maintained for reference or inspection.

9.2 Refer to Method 8000 for specific determinative method QC procedures. Refer to Method 3500 or 5000 for QC procedures to ensure the proper operation of the various sample preparation techniques. If an extract cleanup procedure is performed, refer to Method 3600 for the appropriate QC procedures. Any more specific QC procedures provided in this method will supersede those noted in Methods 8000, 5000, 3500, or 3600.

9.3 Quality control procedures necessary to evaluate the GC system operation are found in Method 8000 and include evaluation of retention time windows, calibration verification and chromatographic analysis of samples. In addition, discussions regarding the instrument QC requirements listed below can be found in the referenced sections of this method:

- The GC/MS must be tuned to meet the recommended DFTPP criteria prior to the initial calibration and for each 12-hr period during which analyses are performed. See Secs. 11.3.1 and 11.4.1 for further details.
- There must be an initial calibration of the GC/MS system as described in Sec. 11.3. In addition, the initial calibration curve should be verified immediately after performing the standard analyses using a second source standard (prepared using standards different from the calibration standards). The suggested acceptance limits for this initial calibration verification analysis are 70 - 130%. Alternative acceptance limits may be appropriate based on the desired project-specific data quality objectives. Quantitative sample analyses should not proceed for those analytes that fail the second source standard initial calibration verification. However, analyses may continue for those analytes that fail the criteria with an understanding these results could be used for screening purposes and would be considered estimated values.
- The GC/MS system must meet the calibration verification acceptance criteria in Sec. 11.4, each 12 hrs.
- The RRT of the sample component must fall within the RRT window of the standard component provided in Sec. 11.6.1.

9.4 Initial demonstration of proficiency

Each laboratory must demonstrate initial proficiency with each sample preparation and determinative method combination it utilizes by generating data of acceptable accuracy and precision for target analytes in a clean matrix. The laboratory must also repeat the following operations whenever new staff members are trained or significant changes in instrumentation are made. See Method 8000 for information on how to accomplish a demonstration of proficiency.

9.5 Initially, before processing any samples, the analyst should demonstrate that all parts of the equipment in contact with the sample and reagents are interference-free. This is accomplished through the analysis of a method blank. As a continuing check, each time samples are extracted, cleaned up, and analyzed, a method blank must be prepared and analyzed for the compounds of interest as a safeguard against chronic laboratory contamination. If a peak is observed within the retention time window of any analyte that would prevent the determination of that analyte, determine the source and eliminate it, if possible, before processing the samples. The blanks should be carried through all stages of sample preparation and analysis. When new reagents or chemicals are received, the lab should monitor the preparation and/or analysis blanks associated with samples for any signs of contamination. It is not necessary to test every new batch of reagents or chemicals prior to sample preparation if the source shows no prior problems. However, if reagents are changed during a preparation batch, separate blanks need to be prepared for each set of reagents.

9.6 Sample quality control for preparation and analysis

The laboratory must also have procedures for documenting the effect of the matrix on method performance (precision, accuracy, method sensitivity). At a minimum, this should include the analysis of QC samples including a method blank, a matrix spike, a duplicate, and a laboratory control sample (LCS) in each analytical batch and the addition of surrogates to each field sample and QC sample when surrogates are used. Any method blanks, matrix spike samples, and replicate samples should be subjected to the same analytical procedures (Sec. 11.0) as those used on actual samples.

9.6.1 Documenting the effect of the matrix should include the analysis of at least one matrix spike and one duplicate unspiked sample or one matrix spike/matrix spike duplicate pair. The decision on whether to prepare and analyze duplicate samples or a matrix spike/matrix spike duplicate must be based on a knowledge of the samples in the sample batch. If samples are expected to contain target analytes, laboratories may use a matrix spike and a duplicate analysis of an unspiked field sample. If samples are not expected to contain target analytes, then laboratories should use a matrix spike and matrix spike duplicate pair. Consult Method 8000 for information on developing acceptance criteria for the MS/MSD.

9.6.2 A laboratory control sample (LCS) should be included with each analytical batch. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS is spiked with the same analytes at the same concentrations as the matrix spike, when appropriate. When the results of the matrix spike analysis indicate a potential problem due to the sample matrix itself, the LCS results are used to verify that the laboratory can perform the analysis in a clean matrix. Consult Method 8000 for information on developing acceptance criteria for the LCS.

9.6.3 Also see Method 8000 for the details on carrying out sample quality control procedures for preparation and analysis. In-house method performance criteria for

evaluating method performance should be developed using the guidance found in Method 8000.

9.7 Surrogate recoveries

If surrogates are used, the laboratory should evaluate surrogate recovery data from individual samples versus the surrogate control limits developed by the laboratory. See Method 8000 for information on evaluating surrogate data and developing and updating surrogate limits. Procedures for evaluating the recoveries of multiple surrogates and the associated corrective actions should be defined in an approved project plan.
